Triple Quadrupole GC/MS System Verification - Tune

Instrument Name	MS47 / US2116V309	**MS Model**	7010B
Tune Date & Time	8/19/2024 2:49:55 PM	**Source**	EI High Efficiency
Tune File	D:\MassHunter\GCMS\1\7010\atunes.eihs.tune.xml Modified		

Instrument Actuals

Ionization mode	EI+
Source Temp.	300 °C
MS1 Quad Temp.	150 °C
MS2 Quad Temp.	150 °C
Filament Current	100.1 µA

Vacuum

Rough Vac	1.48E+2 mTorr
High Vac	7.95E-5 Torr
Turbo 1 Speed	100.0 %
Turbo 1 Power	20.3 W

GC Gas Flow

Quench Flow	2.250 mL/min	Column 1	1.200 mL/min
Collision Cell	1.500 mL/min	Column 2	0.000 mL/min

MS1 Checktune Results

	Value	Limit	Result
Low mass assignment (target 69.00, actual 69.00)	0.00	<= 0.20	OK
Mid mass assignment (target 264.00, actual 264.00)	0.00	<= 0.20	OK
High mass assignment (target 502.00, actual 502.00)	0.00	<= 0.20	OK
Low mass isotope position (target 70.00, actual 70.00)	0.00	<= 0.20	OK
Mid mass isotope position (target 265.00, actual 265.00)	0.00	<= 0.20	OK
High mass isotope position (target 503.00, actual 503.00)	0.00	<= 0.20	OK
Low mass isotope ratio	1.20%	>= 0.5% and <= 1.6%	OK
Mid mass isotope ratio	5.76%	>= 4.2% and <= 6.9%	OK
High mass isotope ratio	9.76%	>= 7.9% and <= 12.3%	OK
Ratio of mid mass to low mass	27.44%	>= 5.0%	OK
Ratio of high mass to low mass	3.81%	>= 0.8%	OK
Low mass precursor ratio	0.24%	<= 3.00%	OK
Mid mass precursor ratio	0.10%	<= 6.00%	OK
High mass precursor ratio	0.05%	<= 12.00%	OK

MS2 Checktune Results

Low mass assignment (target 69.00, actual 69.00)	0.00	<= 0.20	OK
Mid mass assignment (target 264.00, actual 264.00)	0.00	<= 0.20	OK
High mass assignment (target 502.00, actual 502.00)	0.00	<= 0.20	OK
Low mass isotope position (target 70.00, actual 70.00)	0.00	<= 0.20	OK
Mid mass isotope position (target 265.00, actual 265.08)	0.08	<= 0.20	OK
High mass isotope position (target 503.00, actual 503.02)	0.02	<= 0.20	OK
Low mass isotope ratio	1.24%	>= 0.5% and <= 1.6%	OK
Mid mass isotope ratio	5.45%	>= 4.2% and <= 6.9%	OK
High mass isotope ratio	9.45%	>= 7.9% and <= 12.3%	OK
Low mass precursor ratio	0.00%	<= 3.00%	OK
Mid mass precursor ratio	0.00%	<= 6.00%	OK
High mass precursor ratio	0.15%	<= 12.00%	OK

Detector

EMV	1133	<= 2900	OK
Maximum gain factor	8516	>= 100	OK

Bench Sheet Review Check List	
☑	Hold times met; if no, reason:
☑	Prep date, time, method, department, product code correct
☑	Spike information and Q.C. correct (insufficient volume or mass recorded if no Q.C.)
☑	Weights/Volumes and units correct on raw and final bench sheets
☑	Sample IDs have been checked - bottle numbers appended if required
☑	Names present for: started by, completed by, relinquished by, and witnessed by
☑	Extract storage recorded
☑	Additional prep sheet completely filled out (NA or line out blanks)
☑	All clean-ups have been noted on additional prep sheet

Phenanthrene	7.46	+0.01	1187176	855.19	1600		Y
Pyrene	8.63	+0.01	837233	449.06	850		Y

Prep Amount:	10.464 g	**Dilution:**	1
Prep Final Amount:	10.00 mL	**Basis Factor:**	50.50

U: Undetected at or above MDL
J: Analyte detected above MDL, but below MRL
B: Hit above MRL also found in Method Blank
E: Analyte concentration above high point of ICAL
N: Presumptive evidence of compound

D: Result from dilution
m: Manual integration performed
d: Compound manually deleted
NR: Analyte not reported from this analysis

*: Result fails acceptance criteria
#: Acceptance criteria not applicable
?: Insufficient information to determine acceptance
e: Result >= MRL, but MRL less than low point of ICAL
c: check for co-elution

U: Undetected at or above MDL
J: Analyte detected above MDL, but below MRL
B: Hit above MRL also found in Method Blank
E: Analyte concentration above high point of ICAL
N: Presumptive evidence of compound

D: Result from dilution
m: Manual integration performed
d: Compound manually deleted
NR: Analyte not reported from this analysis

*: Result fails acceptance criteria
#: Acceptance criteria not applicable
?: Insufficient information to determine acceptance
e: Result >= MRL, but MRL less than low point of ICAL
c: check for co-elution

U: Undetected at or above MDL
J: Analyte detected above MDL, but below MRL
B: Hit above MRL also found in Method Blank
E: Analyte concentration above high point of ICAL
N: Presumptive evidence of compound

D: Result from dilution
m: Manual integration performed
d: Compound manually deleted
NR: Analyte not reported from this analysis

*: Result fails acceptance criteria
#: Acceptance criteria not applicable
?: Insufficient information to determine acceptance
e: Result >= MRL, but MRL less than low point of ICAL
c: check for co-elution

Surrogate Compounds

Parameter Name	RT	RT Dev	Response	Solution Conc	Rpt?
Fluoranthene-d10	8.41		633554	463.61	Y
Fluorene-d10	6.62		329929	420.59	Y
Terphenyl-d14	8.75		688224	386.26	Y

Target Compounds

Parameter Name	RT	RT Dev	Response	Solution Conc	Rpt?
2-Methylnaphthalene	5.27		343311	395.17	Y
Acenaphthene	6.21		318666	409.13	Y
Acenaphthylene	6.07		518208	427.43	Y
Anthracene	7.49		531847	437.87	Y
Benz(a)anthracene	9.90		923174	440.11	Y
Benzo(a)pyrene	12.77		954153	489.34	Y
Benzo(b)fluoranthene	11.91		1082278	443.10	Y
Benzo(g,h,i)perylene	15.67		1043594	389.16	Y
Benzo(k)fluoranthene	11.97		1009432	437.59	Y
Chrysene	9.95		872989	437.14	Y
Dibenz(a,h)anthracene	15.33		1036380	452.43	Y
Fluoranthene	8.43		651861	434.91	Y
Fluorene	6.65		369852	413.07	Y

U: Undetected at or above MDL
J: Analyte detected above MDL, but below MRL
B: Hit above MRL also found in Method Blank
E: Analyte concentration above high point of ICAL
N: Presumptive evidence of compound

D: Result from dilution
m: Manual integration performed
d: Compound manually deleted
NR: Analyte not reported from this analysis

*: Result fails acceptance criteria
#: Acceptance criteria not applicable
?: Insufficient information to determine acceptance
e: Result >= MRL, but MRL less than low point of ICAL
c: check for co-elution

The following Stage 2A review was performed on the requested analyses. No results were rejected, and analytical completeness is 100%.

Narrative and Completeness Review – The case narrative and data package were checked for completeness. No completeness issues were noted.

Qualification: None required.

Sample Delivery and Condition – All samples arrived at the laboratory with temperatures within 0-6°C or were frozen. Some sample containers were cracked and the samples were transferred to new containers. Some samples were noted to be missing the dates and times, in which case the laboratory logged these samples in accordance with the information on the custody form.

Qualification: None required.

Holding Times – All samples were frozen. The samples collected in July 2022 were prepared more than 1 year outside of 1 year holding time for frozen samples. Due to the stable nature of PCDD/PCDFs, it is the judgment that all results from July 2022 samples can be accepted with the qualification of J-HTPX (detections) or UJ-HTPX (non-detections). The samples collected in August 2022 were prepared within 2 years of collection and all results from August 2022 should be qualified J-HTP (detections) or UJ-HTP (non-detections).

Qualification: **All results for July 2022 samples are qualified of J-HTPX (detections) or UJ-HTPX (non-detections)**. **All results for August 2022 samples are qualified of J-HTP (detections) or UJ-HTP (non-detections)**.

Method Blanks – The method blank for preparation batch 56594 was contaminated with several analytes, including:

- 0.162 pg/g of 1,2,3,7,8-PeCDD, leading to a qualification limit of 0.81 pg/g
- 1.15 pg/g of 1,2,3,4,6,7,8,9-OCDD, leading to a qualification limit of 5.75 pg/g
- 0.138 pg/g of 1,2,3,4,7,8-HxCDF, leading to a qualification limit of 0.69 pg/g
- 0.104 pg/g of 2,3,4,6,7,8-HxCDF, leading to a qualification limit of 0.52 pg/g
- 0.404 pg/g of 1,2,3,4,6,7,8-HpCDF, leading to a qualification limit of 2.02 pg/g

The following detected results were below the associated qualification limit and should be qualified U:

- The 1,2,3,7,8-PeCDD results for samples SIB-SC-B31-7-8-07/10/2022 and SIB-SC-B32-8-9-07/25/2022
- The 1,2,3,4,6,7,8,9-OCDD results for samples SIB-SC-B31-7-8-07/10/2022, SIB-SC-B31-10-11-07/10/2022, and SIB-SC-B34-0-1-08/22/2022
- The 1,2,3,4,7,8-HxCDF results for samples SIB-SC-B31-7-8-07/10/2022, SIB-SC-B31-8-9-07/10/2022, SIB-SC-B31-9-10-07/10/2022, SIB-SC-B31-11-12-07/10/2022, SIB-SC-B31-13-13.7-07/10/2022, SIB-SC-B32-8-9-07/25/2022, and SIB-SC-B35-0-1-07/07/2022
- The 2,3,4,6,7,8-HxCDF results for sample SIB-SC-B31-7-8-07/10/2022
- The 1,2,3,4,6,7,8-HpCDF result for samples SIB-SC-B31-6-7-07/10/2022, SIB-SC-B31-7-8-07/10/2022, SIB-SC-B31-8-9-07/10/2022, SIB-SC-B31-9-10-07/10/2022, SIB-SC-B31-10-11-07/10/2022, SIB-SC-B31-11-12-07/10/2022, SIB-SC-B31-12-13-07/10/2022, SIB-SC-B31-13-13.7-07/10/2022, SIB-SC-B32-7-8-07/25/2022, SIB-SC-B34-0-1-08/22/2022, SIB-SC-B34-8-9-08/22/2022, SIB-SC-B34-9-9.7-08/22/2022, and SIB-SC-B35-0-1-07/07/2022

The method blank for batch 56680 was contaminated with several analytes, including:

- 0.496 pg/g of 1,2,3,4,6,7,8,9-OCDD, leading to a qualification limit of 2.48 pg/g
- 0.138 pg/g of 1,2,3,7,8-PeCDF, leading to a qualification limit of 0.69 pg/g
- 0.134 pg/g of 2,3,4,7,8-PeCDF, leading to a qualification limit of 0.67 pg/g
- 0.174 pg/g of 1,2,3,6,7,8-HxCDF, leading to a qualification limit of 0.87 pg/g
- 0.288 pg/g of 1,2,3,4,6,7,8-HpCDF, leading to a qualification limit of 1.44 pg/g

The 1,2,3,4,6,7,8-HpCDF results for samples SIB-SC-B35-6-7-07/07/2022, SIB-SC-B35-7-8-07/07/2022, SIB-SC-B35-8-9-07/07/2022, SIB-SC-B35-9-10-07/07/2022, SIB-SC-B35-10-11-07/07/2022, SIB-SC-B35-11-12-07/07/2022, SIB-SC-B35-12-13-07/07/2022, and SIB-SC-B35-14-14.7-07/07/2022 should be qualified U.

Qualification: **The following results were qualified U-MBL; the detect_flag for the affected results is changed from Y to N.**

- **The 1,2,3,7,8-PeCDD results for samples SIB-SC-B31-7-8-07/10/2022 and SIB-SC-B32-8-9-07/25/2022**
- **The 1,2,3,4,6,7,8,9-OCDD results for samples SIB-SC-B31-7-8-07/10/2022, SIB-SC-B31-10-11-07/10/2022, and SIB-SC-B34-0-1-08/22/2022**
- **1,2,3,4,7,8-HxCDF results for samples SIB-SC-B31-7-8-07/10/2022, SIB-SC-B31-8-9-07/10/2022, SIB-SC-B31-9-10-07/10/2022, SIB-SC-B31-11-12-07/10/2022, SIB-SC-B31-13-13.7-07/10/2022, SIB-SC-B32-8-9-07/25/2022, and SIB-SC-B35-0-1-07/07/2022**
- **The 2,3,4,6,7,8-HxCDF result for sample SIB-SC-B31-7-8-07/10/2022**
- **The 1,2,3,4,6,7,8-HpCDF results for samples SIB-SC-B31-6-7-07/10/2022, SIB-SC-B31-7-8-07/10/2022, SIB-SC-B31-8-9-07/10/2022, SIB-SC-B31-9-10-07/10/2022, SIB-SC-B31-10-11-07/10/2022, SIB-SC-B31-11-12-07/10/2022, SIB-SC-B31-12-13-07/10/2022, SIB-SC-B31-13-13.7-07/10/2022, SIB-SC-B32-7-8-07/25/2022, SIB-SC-B34-0-1-08/22/2022, SIB-SC-B34-8-9-08/22/2022, SIB-SC-B34-9-9.7-08/22/2022, and SIB-SC-B35-0-1-07/07/2022**
- **The 1,2,3,4,6,7,8-HpCDF results for samples SIB-SC-B35-6-7-07/07/2022, SIB-SC-B35-7-8-07/07/2022, SIB-SC-B35-8-9-07/07/2022, SIB-SC-B35-9-10-07/07/2022, SIB-SC-B35-10-11-07/07/2022, SIB-SC-B35-11-12-07/07/2022, SIB-SC-B35-11-12-07/07/2022, SIB-SC-B35-14-14.7-07/07/2022 should be qualified U.**

Rinsate Blanks – Equipment rinse blank EB01-07/12/2022 (results reported in SDG 20046) is associated with all sample collected on July 7, 10, and 12, 2022 and equipment blank EB05-07/26/2022 (results reported in SDG 20123) is associated with all samples collected on July 25, 2022. Both equipment blanks were free from contamination.

Equipment rinse blank EB09-08242022 (results reported in SDG 20283) is associated with all samples in this SDG that were collected on 8/22/22. This rinse blank was contaminated with 14 PCDD/PCDFs. The OCDD and 1,2,3,4,6,7,8-HpCDF results are attributable to aqueous preparation batch contamination and are not considered to be the result of cross-contamination in the field; however, this equipment blank was contaminated with 12 other PCDD/PCDF analytes. Due to the differences in preparation factors between aqueous and solid samples, the HGL reviewer determined that a concentration reported as X pg/L in the rinse blank corresponds approximately to a relative soil concentration of X/10 pg/g. The contamination in the equipment blank and the corresponding soil action levels are presented in the following table.

Analyte	Aqueous Concentration (pg/L)	Equivalent Soil Concentration (pg/g)	Soil Qualification Level (pg/g)
1,2,3,7,8-PeCDD	2.36	0.236	1.18
1,2,3,4,7,8-HxCDD	1.58	0.158	0.790
1,2,3,6,7,8-HxCDD	1.58	0.158	0.790
1,2,3,7,8,9-HxCDD	1.84	0.184	0.920
1,2,3,4,6,7,8-HpCDD	1.39	0.139	0.695
1,2,3,7,8-PeCDF	2.78	0.278	1.39
2,3,4,7,8-PeCDF	2.34	0.234	1.17
1,2,3,4,7,8-HxCDF	2.32	0.232	1.16
1,2,3,6,7,8-HxCDF	1.97	0.197	0.985
2,3,4,6,7,8-HxCDF	1.15	0.115	0.575
1,2,3,7,8,9-HxCDF	1.37	0.137	0.685
1,2,3,4,7,8,9-HpCDF	1.37	0.137	0.685

The 1,2,3,7,8,9-HxCDD result for sample SIB-SC-B34-7-8-08/22/2022 and the 1,2,3,6,7,8-HxCDD and 1,2,3,7,8,9-HxCDD results for sample SIB-SC-B34-8-9-08/22/2022 should be qualified U. All other results associated with this equipment rinse blank were non-detections or detected results greater than the qualification level.

Qualification: **The 1,2,3,7,8,9-HxCDD result for sample SIB-SC-B34-7-8-08/22/2022 and the 1,2,3,6,7,8-HxCDD and 1,2,3,7,8,9-HxCDD results for sample SIB-SC-B34-8-9-08/22/2022 are qualified U-EBL.**

Laboratory Control Sample (LCS) and Laboratory Control Sample Duplicate (LCSD) – LCS/LCSD %Rs were within QAPP control limits. All RPDs were within QAPP control limits.

Qualification: None required.

Surrogates – All surrogates were within control limits.

Qualification: None required.

Matrix Spike/Matrix Spike Duplicate (MS/MSD) – An MS/MSD was performed using sample SIB-SC-B31-6-7-07/10/2022. All %Rs and RPDs were within control limits.

Qualification: None required.

Field Duplicate – No field duplicates were submitted with this SDG.

Qualification: None required.

Compound Quantitation – Analyte non-detections were reported as the EDL and qualified U. Analytes detected between the EDL and PQL were reported as J-qualified results by the laboratory. These J qualifiers were retained unless superseded by a more severe qualifier.

If a detected analyte has an ion ratio outside the characteristic ion ratio window, the result is reported as an estimated maximum potential concentration. All results reported as an EMPC (a "K" flag is present in the laboratory qualifier) are qualified J-EMPC unless superseded by a higher priority qualifier.

2,3,7,8-TCDF is not fully resolved on the DB-5MS column; when detected above the PQL on the DB-5MS column, the result was confirmed on a DB-225 column using the instrument ID listed in the case narrative. In cases where two results are reported for 2,3,7,8-TCDF for a sample, the result from the DB-225 column is selected for use and the result from the DB-5MS is qualified DNR-EXC.

Qualification: **The following results are qualified:**

- **All results reported with a laboratory qualifier of only K are qualified J with reason code EMPC. All results reported with a laboratory qualifier of BJK or JK are qualified as simply J to remove non-standard informational qualifiers and to be replaced with a valid final qualifier.**
- **All 2,3,7,8-TCDF results reported from the DB-5MS column that are paired with a 2,3,7,8-TCDF result from the DB-225 column are qualified DNR, reason code EXC; note that the reportable_result field for these results are populated with "Yes" by the laboratory and are changed to "No" for the affected results.**

Qualification Summary Table (results in pg/g):

In addition to the qualifiers assigned below, all detected results <PQL retain the J qualifier assigned by the laboratory. All non-standard qualifiers assigned by the laboratory are removed and are not included as the final qualifier.

Sample	Analyte	Lab Value	Lab Qualifier	Validated Value	Validated Qualifier	Reason Code

The following Stage 2A review was performed on the requested analyses. No results were rejected, and analytical completeness is 100%.

Narrative and Completeness Review – The case narrative and data package were checked for completeness. The narrative noted internal standard and ICV/CCV discrepancies. All this has been noted but falls outside of a 2A validation.

Qualification: None required.

Sample Delivery and Condition – All samples arrived intact at the laboratory with temperatures between 0-6°C or frozen and were properly preserved. Lab noted cooler arrived without signed and dated custody seals, and without a temperature blank. No additional qualification required.

Qualification: None required.

Holding Times –The narrative noted that PCB Aroclors samples were frozen to extend holding times; this is in accordance with the QAPP archiving protocols. All Aroclor samples were extracted approximately 12 months beyond the 1-year holding time for frozen Aroclors sample preparation. There is no holding time for PCBs in soil/sediment samples and no qualification is required.

Qualification: None required.

Method Blanks – All method blanks were free from contamination.

Qualification: None required.

Rinsate Blanks – Equipment rinse blanks EB01-07/12/2022, EB05-07/26/2022, and EB08-08/21/2022 (results reported in SDGs 22G0258, 22G0436, and 22H0491) are associated with all sample results reported in this SDG. All rinse blanks were free from contamination.

Qualification: None required.

Laboratory Control Sample (LCS) and Laboratory Control Sample Duplicate (LCSD) – All LCS/LCSD %Rs and RPDs were within QAPP control limits. A standard reference material was also reported for each preparation batch; all SRM %Rs met the control limits.

Qualification: None required.

Surrogates – All surrogate %R were within QAPP control limits except for:

- The original analysis of sample SIB-SC-E24-7-8-07/12/2022 showed a high %R for surrogate decachlorobiphenyl on column 1 and a low %R on column 2. All detected results reported for this analysis are reported from column 2 and should be qualified J-SSL. All non-detected results reported for this analysis are reported from column 1 and do not require qualification.
- The 5x diluted analysis of sample SIB-SC-E24-7-8-07/12/2022 had three of the four reported surrogate %Rs below the control limits; no results from this analysis are reported and all results for this analysis should be qualified DNR-EXC.
- Sample SIB-SC-E24-8-9-07/12/2022 had a high %R for surrogate decachlorobiphenyl on column 1 and a low %R for surrogate decachlorobiphenyl on column 2. All detected results reported for

this analysis are reported from column 2 and should be qualified J-SSL. All non-detected results reported for this analysis are reported from column 1 and do not require qualification.

- Sample SIB-SC-J06-8-9-07/26/2022 did not report surrogate values due to intense dilution effects. This sample was analyzed at a 100x dilution.

Qualification: **The following results were adjusted to change the reported_result field from Yes to No: all results from the 5x diluted analysis of sample SIB-SC-E24-7-8-07/12/2022. These results are qualified DNR-EXC.**

The following detected results were qualified J-SSL: Aroclors 1248, 1254, and 1260 for samples SIB-SC-E24-8-9-07/12/2022 and the original analysis of sample SIB-SC-E24-7-8-07/12/2022.

- **Aroclors 1248, 1254, and 1260 for the 5x dilution reanalysis of sample SIB-SC-E24-7-8-07/12/2022 with reason code SSL.**

Matrix Spike/Matrix Spike Duplicate (MS/MSD) – The MS and MSD performed on sample SIB-SC-B31-7-8-07/10/2022 had all %Rs and RPDs in control. The MS and MSD performed on sample SIB-SC-J06-8-9-07/26/2022 had a low %R for Aroclor-1260 in the MS and high %Rs for Aroclor 1016 in the MS and for Aroclors 1016 and 1260 in the MSD; the Aroclor 1260 RPD was above the control limit. The parent sample was analyzed at 100x dilution due to elevated concentrations of multiple Aroclors and matrix effects. The matrix effects confirmed are in the MS/MSD; however, since the parent sample was diluted 100x, these matrix effects should be mitigated and in the judgment of the HGL reviewer, no qualification is required.

The laboratory included a standard reference matrix sample in each preparation batch. All SRM %Rs were in control.

Qualification: None required.

Field Duplicate – A field duplicate was not submitted with the samples in this SDG.

Qualification: None required.

Laboratory Duplicate – A laboratory duplicate was not performed in this SDG.

Qualification: None required.

Compound Quantitation – Analyte results were reported with the associated DL, LOD, and LOQ in the DoD format instead of with the associated MDL and RL. Non-detected results were reported on the hardcopy as <#, where # corresponds to the LOD. The HGL reviewer confirmed that the value associated with non-detected results in the EDD is the MDL, in accordance with the project reporting requirements. Analytes detected between the MDL and LOQ were reported as J-qualified results by the laboratory. These J qualifiers were retained unless superseded by a more severe qualifier.

Qualification: None required.

Qualification Summary Table (concentrations in µg/kg):

Sample	Analyte	Lab Value	Lab Qualifier	Validated Value	Validated Qualifier	Reason Code
SIB-SC-E24-8-9-07/12/2022	Aroclor 1248	101	H, P1	101	J	SSL

The following Stage 2A review was performed on the requested analyses. No results were rejected, and analytical completeness is 100%.

Narrative and Completeness Review – The case narrative and data package were checked for completeness. No completeness issues were noted.

Qualification: None required.

Sample Delivery and Condition – Sample delivery and condition were checked; no issues were found.

Qualification: None required.

Holding Times – All samples were prepared outside their acceptable holding times; however, this is acceptable for pesticides and PAHs. Due to pesticides and PAHs potentially not being environmentally stable over an extended period of time, all detects should be qualified J and all non-detects should be qualified UJ.

Qualification: **All detects should be qualified J, and all non-detects should be qualified UJ.**

Method Blanks – The method blank for Method 1699M was free from contamination and no qualification is required.

The method blank for Method 8270D had 0.35 ug/kg benz(a)anthracene, 0.49 ug/kg naphthalene, and 0.36 ug/kg pyrene present leading to qualification limits of 1.75 ug/kg, 2.45 ug/kg, and 1.8 ug/kg, respectively. All associated results are detections >5x the qualification limits and no qualification of sample results is required.

Qualification: None required.

Rinsate Blanks – There was not a rinsate blank associated with this SDG. No qualification required.

Qualification: None required.

Laboratory Control Sample (LCS) – LCS %Rs for Method 1699M were within QAPP control limits, except for 2,4'-DDT which was at 124% and 4,4'-DDT which was at 144%. No qualification is required since the sample results did not yield any detections for these two analytes.

All LCS %Rs for Method 8270D were within QAPP control limits. No qualification is required.

Qualification: None required.

Surrogates – All surrogates for Method 1699M were within control limits, except for the following:

- Endrin-13C12 which was at 156% for sample SIB-SC-E24-8-9-07/12/2022.
- Endrin-13C12 which was at 172% for sample SIB-SC-E24-9-10-07/12/2022.
- 4,4'-DDT-d4 which was at 1334% and S_Endrin-13C12 which was at 165% for sample SIB-SC-J06-8-9-07/26/2022.

All results associated with high pesticide surrogate results are non-detections. All surrogates for Method 8270D were within control limits. No qualification is required for either method.

Qualification: None required.

Matrix Spike/Matrix Spike Duplicate (MS/MSD) – An MS/MSD was performed for Method 1699M using sample SIB-SC-E24-7-8-07/12/2022. All %R and RPD values were within control limits except for the following:

- Aldrin %R for the MS was 892% and the %R for the MSD was 723%
- 2,4'-DDD %R for the MS was 137% and the %R for the MSD was 162%
- 4,4'-DDD %R for the MSD was 163%
- 2,4'-DDT %R for the MSD was 37% and the RPD was 75%
- 4,4'-DDT %R for the MSD was 0% and the RPD was not calculated
- cis-Nonachlor %R for the MS was 45% and the %R for the MSD was 49%
- Oxychlordane %R for the MS and MSD was 0% and the RPD was not calculated.

The following qualifications should be applied:

- 4,4'-DDD result for sample SIB-SC-E24-7-8-07/12/2022 should be qualified J.
- 2,4'-DDT result for sample SIB-SC-E24-7-8-07/12/2022 should be qualified UJ.
- 4,4'-DDT result for sample SIB-SC-E24-7-8-07/12/2022 should be qualified UJ; although the MSD %R was 0%, the MS %R was in control.
- cis-Nonachlor results for sample SIB-SC-E24-7-8-07/12/2022 should be qualified UJ.
- Oxychlordane results for sample SIB-SC-E24-7-8-07/12/2022 should be qualified R.

An MS/MSD was performed for Method 8270D using sample SIB-SC-E24-7-8-07/12/2022. All %R and RPD values are within control limits, except the following:

- 2-methylnapthalene %R for the MS was 102%

The following qualifications should be applied:

- 2-methylnaphthalene result for sample SIB-SC-E24-7-8-07/12/2022 should be qualified J.

- ***Qualification:*** **The 4,4'-DDD results for sample SIB-SC-E24-7-8-07/12/2022 is qualified J-MSH. The 2,4'-DDT and cis-nonachlor results for sample SIB-SC-E24-7-8-07/12/2022 are qualified UJ-MSL. The 4,4'-DDT result for sample SIB-SC-E24-7-8-07/12/2022 is qualified UJ, reason code MSLX. The oxychlordane result for sample SIB-SC-E24-7-8-07/12/2022 is qualified R-MSLX. The 2-methylnaphthalene result for sample SIB-SC-E24-7-8-07/12/2022 is qualified J-MSH.**

Field Duplicate – No field duplicates were submitted with this SDG.

Qualification: None required.

Compound Quantitation – Analyte non-detections were reported as ND and qualified U. Analytes detected between the MDL and MRL were reported as J-qualified results by the laboratory. These J qualifiers were retained unless superseded by a more severe qualifier.

Qualification: None Required.

Qualification Summary Table (results in ug/kg):

In addition to the qualifiers assigned below, all detected results <MRL retain the J qualifier assigned by the laboratory. All non-standard qualifiers assigned by the laboratory are removed and are not included as the final qualifier.

Sample	Analyte	Lab Value	Lab Qualifier	Validated Value	Validated Qualifier	Reason Code
SIB-SC-E24-7-8-07/12/2022	4,4'-DDD	6.1	--	6.1	J	MSH, HTP

APPENDIX C

HABITAT IMPACT EVALUATION TECHNICAL MEMORANDUM

EARLIER SUBMITTAL TO EPA (SEPTEMBER 17, 2025)

This page was intentionally left blank.

HABITAT IMPACT EVALUATION TECHNICAL MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
REMEDIAL DESIGN SERVICES, SWAN ISLAND BASIN PROJECT AREA
CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

1.0 INTRODUCTION AND PURPOSE

This Habitat Impact Evaluation (HIE) assesses the net effect the Remedial Action (RA) would have on habitat conditions within the Swan Island Basin (SIB) Project Area. This HIE provides the basis for the U.S. Environmental Protection Agency (EPA) to determine whether the RA would be "self-mitigating" with respect to impacts to Waters of the U.S. and associated ecological functions within the SIB Project Area.

The SIB Project Area is within the Portland Harbor Superfund Site (PHSS) in Portland, Multnomah County, Oregon. This HIE evaluates habitat impacts that would result from the RA for the SIB Project Area to support EPA's determination whether the RA will require compensatory mitigation to address unavoidable impacts to habitats. The habitat-related requirements specified in the PHSS Record of Decision (ROD) (EPA, 2017) and the Administrative Settlement Agreement and Order on Consent (ASAOC) (EPA, 2021a) are incorporated into the Pre-Final 90% RD. The ROD anticipates that application of those requirements should result in an RA that yields a net improvement in overall habitat conditions compared to existing pre-RA baseline habitat conditions.

The purpose of this HIE is to complete a quantitative analysis of habitat impacts to either confirm the project will be self-mitigating or to determine that compensatory mitigation is needed and provide a basis for determining the amount and type of mitigation required. This HIE was performed as described in the Remedial Design Work Plan (RDWP), which was approved by EPA on February 28, 2025. The baseline habitat conditions data supporting this HIE were reported and evaluated in the Pre-Design Investigation (PDI) Evaluation Report (ER) (HGL, 2024). The anticipated post-RA habitat conditions are based on the final surface conditions specified in the Pre-Final 90% RD.

This HIE is conducted following the Remedial Design Guidelines and Considerations (RDGC) (EPA, 2021b) to demonstrate that the RA as envisioned in the Pre-Final 90% Remedial Design (RD) will comply with action-specific or location-specific applicable or relevant and appropriate requirements (ARARs) pertaining to habitat and ecological functions within the SIB Project Area. This memorandum presents the evaluation of the net effect of the RA on habitat conditions by comparing the anticipated post-RA habitat conditions to pre-RA baseline habitat conditions within the SIB Project Area. Post-RA habitat conditions used in this evaluation reflect the application of required habitat avoidance and minimization measures outlined in the 2021 Programmatic Biological Assessment (BA) (EPA, 2021c), the 2025 Programmatic Biological Opinion (BO) (NMFS, 2025), the RDGC (EPA, 2021b), and the PHSS ROD (EPA, 2017).

1.1 SITE DESCRIPTION AND HISTORY

The SIB Project Area is the active cleanup area within the PHSS that lies between approximately river mile (RM) 8.1 and RM 9.2 on the northeast side of the Willamette River. The SIB Project Area is approximately 1.1 miles in length and 139 acres in size and includes riverbanks from the top of the bank to the river. The SIB Project Area is adjacent to a federal navigation channel within the main channel of the Willamette River. The navigation channel has an authorized maintained depth of -45 feet (ft) Columbia River Datum (CRD), extending from the confluence of the Lower Willamette River with the Columbia River to RM 11.6. The U.S. Army Corps of Engineers (USACE) maintains the navigation channel, which does not extend into SIB.

The SIB Project Area is bounded by the uplands of Swan Island and Mocks Bottom to the southwest and northeast, respectively. Land use within and adjacent to the SIB Project Area includes light industrial, heavy industrial, and commercial. SIB is an active navigable industrial waterway, and the shoreline hosts many structures supporting light and heavy industrial activities. Except for slopes along the riverbanks, the basin upland topography is generally flat, with elevations varying between +34 ft and +44 ft North American Vertical Datum of 1988 (NAVD88)[1].

The Portland Harbor reach of the Willamette River, including the SIB Project Area, has been dredged, redirected, straightened, filled, and deepened. Most of the riverbank has been filled, stabilized, and engineered for industrial-type operations with riprap, bulkheads, and overwater piers and docks.

1.2 HABITAT EQUIVALENCY ANALYSIS METHODS AND APPROACH

The RDGC, in Appendix B Topic 9 – Habitat Mitigation (EPA, 2021b), presents EPA guidance and framework on how to apply a habitat equivalency analysis (HEA) model approach to perform a quantitative comparison of post-RA habitat conditions to pre-RA baseline habitat conditions. The National Marine Fisheries Service (NMFS) previously prepared a HEA model for the PHSS in cooperation with the Portland Harbor Trustee Council (EPA, 2021b). EPA distributed an updated HEA model template spreadsheet to the SIB RD Team by email on August 14, 2025. The updated HEA model incorporated the time component of the HEA to ensure that the scoring results consider the temporary functional loss of habitats during RA implementation, and the time required for post-RA habitat conditions to reach full ecological function (0 to 5 years for the habitat types anticipated at the SIB Project Area). The quantitative HEA is the tool EPA uses to evaluate if the RA is "self-mitigating" by determining if RA implementation would result in a positive or negative HEA score reported in "Discounted Service Acre Years" (DSAYs). A positive total DSAY score would indicate that the RA is "self-mitigating," while a negative total DSAY score would indicate that additional compensatory mitigation is needed to address the net impacts of RA implementation. The quantity of additional compensatory mitigation would be determined by the ecological deficit calculated by the HEA model.

[1] 5.28 ft NAVD88 = 0 ft CRD. CRD is used as the nautical chart datum for the Lower Willamette River. CRD is a reference plane that the U.S. Army Corps of Engineers (USACE) established in 1912 by observing low water elevations at various points along the Columbia and Willamette rivers (USACE, 1966). Consequently, CRD is not a fixed/level datum but slopes upward as one moves upstream. River users can obtain the depth on a chart and apply tide or river-level gauge readings, relative to CRD, to compute actual water depth. Low water values are used for navigation charting to provide conservative depth values in the event accurate tide data is not available to the river user.

The HEA model is a spreadsheet-based habitat analysis tool designed to support an ecological valuation of diverse habitat types in various states of ecological health or degradation. The model functions by tabulating the acreage of different habitat types, assigning a habitat score to each unit, and summing the products of collective areas and scores. In addition, the effects of time are incorporated into the HEA calculation by considering the duration of temporary impacts incurred during RA implementation and the time required for post-RA habitat conditions to reach full ecological function. This tabulation and calculation are performed for both pre-RA baseline conditions and post-RA habitat conditions based on the final surface conditions shown in the Pre-Final 90% RD. Habitat scores are affected by certain physical attributes of the habitat units such as vegetation conditions, slope, sediment surface composition, presence of riprap or other armoring, and presence of pilings or structures. Details of the scoring system are shown on Table 1-1, which is based on Table B9-1 in Appendix B of the RDGC (EPA, 2021b) and the HEA model template spreadsheet distributed by EPA on August 14, 2025. The HEA model reports overall habitat values in units of DSAYs, which incorporate consideration of the ecological services provided by specific habitat types, the acreage of habitat that provides those services, and the time-variable habitat function scores as they are affected by temporary impacts during RA construction and the time required for post-RA habitats to reach full ecological function. Reported HEA scores are based on the individual line-item scores achieved when the habitat reaches full function, which is zero to five years for all applicable habitat improvements within the SIB Project Area. The HEA model identifies four habitat types based on elevation ranges with respect to defined water levels in the Willamette River.

- **Riparian Habitat Zone** – The riparian habitat zone includes the riverbanks from ordinary high water (OHW) up to the top of bank (SIB Project Area boundary). OHW is +20.1 ft NAVD88 as defined in the *Guidance for Riverbank Characterizations and Evaluations at the Portland Harbor Superfund Site* (EPA, 2025).
- **Active Channel Margin** – The active channel margin (ACM) habitat zone includes the zone where the edge of water meets the riverbanks. The ACM is defined as the elevation zone between ordinary low water (OLW) and OHW. OLW is defined as +7.3 ft NAVD88[2].
- **Main Channel, Shallow Water** – The main channel shallow water zone is defined as the shoreline between water depths of 0 ft (+7.3 ft NAVD88) and 20 ft (-12.7 ft NAVD88) when the river stage is at OLW[3].
- **Main Channel, Deep Water** – The main channel deep water zone is located below shallow water (below -12.7 ft NAVD88).

Each of these habitat zones is subdivided into specific categories for scoring as shown on Table 1-1.

[2] In earlier evaluations at PHSS, OLW was defined as +5.1 ft NAVD88 and OHW as +20.075 ft NAVD88 (Anchor QEA, 2012). However, in the HEA, the MLW elevation of +7.3 ft NAVD88, as measured at the U.S. Geological Survey 14211720, Morrison Street Bridge gage, is used as an approximation of OLW for SIB.

[3] The ROD uses the NMFS definition of the shallow water habitat zone as above -15 feet CRD (EPA, 2017). The most recent HEA model workbook distributed by EPA on August 14, 2025, defines the shallow water zone as an area of water depth below the OLW elevation. As such, the HEA uses the following elevations as the extent of the shallow water zone: +7.3 ft NAVD88 for water depth of 0 ft and -12.7 ft NAVD88 for water dept of 20 ft, when the river stage is at OLW.

The results of the baseline habitat condition survey included in the PDI ER (HGL, 2024) informed the development of inputs to the HEA for pre-RA baseline habitat conditions. Those model inputs include the acreage of habitat units within the SIB Project Area, and HEA habitat values for each of those habitat units developed using Table 1-1.

Inputs to the HEA model for post-RA habitat conditions were developed based on the Pre-Final 90% RD finished surface conditions superimposed on the map of habitat units. In the same approach used for the pre-RA baseline habitat conditions scenario, the HEA habitat values for post-RA habitat units were developed using Table 1-1.

The HEA model was used to evaluate habitat impacts and improvements as envisioned in the Pre-Final 90% RD. This HEA will be updated as part of the Final 100% RD milestone.

2.0 BASELINE HABITAT CONDITIONS

The habitat condition survey conducted during the PDI (PDI ER, Appendix J [HGL, 2024]) established the baseline existing habitat conditions within the SIB Project Area. Baseline habitat conditions were used to determine pre-RA baseline habitat scores in the HEA model analysis. The habitat areas within the SIB Project Area include four components that align with the vertical habitat types defined in the HEA model:

- riparian areas,
- ACM,
- shallow water habitat, and
- deep water habitat.

These components are defined and discussed below. Riparian areas and ACM are discussed together as part of baseline riverbank habitat conditions. Shallow water and deep water habitats are discussed together as baseline aquatic habitat conditions.

2.1 BASELINE RIVERBANK HABITAT CONDITIONS

For purposes of this analysis, riverbanks are characterized by two habitat zones comprised of riparian areas and the ACM. Riparian areas in the Lower Willamette ecosystem are typically dominated by a mix of black cottonwood and alder/conifer forest, while plant communities in the ACM are typically comprised of facultative scrub/shrub species such as Pacific willow. Riverbanks play a critical role in supporting the life history strategies of many native species of the Pacific Northwest. Influences of the riverbank region, which see diurnal, tidal, and seasonal influences, play an essential role in the viability, functionality, and availability of habitat for an array of native species. EPA has emphasized the importance of incorporating riparian and in-river improvements to support these essential functions in the RDGC, Section 4.

> "*For riverbanks, the planning process involves early coordination with the natural resource service agencies, National Marine Fisheries Service, and U.S. Fish and Wildlife Service to ensure incorporation of riparian and in-river habitat improvements into the riverbank remedial design process. The coordination process is described in PHSS ROD Section 15.2.2 as part of the*

requirements for compliance with location-specific ARARs during the implementation of cleanups. Failure to consult with the agencies early in the remedial design process could result in design changes that could delay a remediation project." (EPA, 2021b)

2.1.1 Riparian Habitat Conditions

The riparian area comprises all upland areas above OHW (+20.1 NAVD88 [+14.8 ft CRD]), up to 400 linear ft upland of the ACM. The SIB Project Area boundary extends only to the top of the riverbank, and riparian areas landward of that boundary are outside the scope of the RD. Riparian habitat provides allochthonous biotic inputs to the aquatic food web, a sediment and contaminant runoff filter, floodwater storage, slope stability, and erosion control.

The following are descriptions of project area-specific riparian area types, the extent, and general conditions (vegetation, slope, armoring, and presence of buildings, structures, and impervious surfaces) of the SIB Project Area derived from the PDI ER (HGL, 2024).

2.1.1.1 Riparian Types

Riparian areas within the SIB Project Area are bound by development consisting of commercial and industrial uses ranging between 0 and 100 ft above OHW. The areas between impervious surfaces and structures and OHW have been divided into the following types that align with the habitats and habitat characteristics shown on Table 1-1:

- Naturally vegetated forest, less than 400 ft from active channel margin – 1.11 acres
- Invasive species (e.g., Himalayan blackberry) – 2.08 acres
- Vegetated riprap – 4.30 acres
- Unvegetated/paved/buildings/riprap – 1.62 acres

Much of the tip of Swan Island, at the mouth of SIB, is formed with a sheet pile bulkhead and an overlying pile-supported wharf. The area beneath the wharf is not considered a riparian area for the purposes of the RD. The areas above OHW beneath the wharf consist of steep slopes shored by sheet pile walls.

2.1.1.2 Riparian Extent

Riparian zone habitats occupy 9.10 acres within the SIB Project Area. As described above, most of the riparian area footprint comprises commercially/industrially developed areas. The general extents of riparian habitat reported here were determined based on field estimates and GIS mapping reported in the baseline habitat survey included in the Habitat Conditions Survey Report (Appendix J of the PDI ER; HGL, 2024) and updated by the GIS spatial analysis applied to the Pre-Final 90% RD to develop inputs to the HEA model.

2.1.1.3 General Conditions

General riparian condition is poor through much of the SIB Project Area. Some stands of mature cottonwood exist, but are mostly present in small, scattered patches, offering little continuity. There is

one exception with the riparian forest located on the Mocks Bottom side of the SIB Project Area (Transects 070 to 079), near the head of the basin, as documented in the PDI ER (HGL, 2024)[4], in which there is a more extensive vegetated buffer on shallow slopes with an overstory consisting of mature native trees (black cottonwood, red alder, and Oregon white oak). In contrast to the overstory, the understory at this location is dominated by invasive species (Himalayan blackberry and English ivy). There are examples of some riparian improvement efforts in locations. However, invasive species are prevalent throughout the riparian zone within the SIB Project Area.

Surface substrate conditions are generally sandy loams with some gravels, largely protected by quarry spall and/or riprap armoring. In the more quiescent inner basin locations these sandy loams are largely unprotected.

2.1.2 Active Channel Margin

The ACM is the portion of the river's edge from the OHW mark to OLW (NOAA, 2017). Figure 3 of *Guidance for River Bank Characterizations and Evaluations at the Portland Harbor Superfund Site* (EPA, 2025) presents riverbank conceptual diagrams as cross sections and includes datum for OHW (+20.1 ft NAVD88), mean high water (MHW; +13.0 ft NAVD88), and mean low water (MLW) (+7.3 ft NAVD88).

The ACM provides canopy cover that serves as a shelter for wildlife (and aquatic species during extended high-water events), provides shade that regulates temperature in the shallow water areas, and contributes beneficial large woody debris (LWD) to the shoreline. The habitat in this area can be valuable to juvenile salmon by providing refuge from predators and a location to escape strong currents. Young-of-the-year (less than one year in age) Chinook move in association with the shoreline edge, and persistent vegetation can be significant to their survival. For the ACM to be considered vegetated, it should contain a facultative assemblage of water-tolerant trees and shrubs. Structural complexity in this zone, such as undulating or irregularly shaped shoreline interlaced with LWD and shade-protected topographic diversity, is desirable, both from a geomorphic perspective (sustained undulations create flow complexities) and from an aspect of providing locations for fish to escape from strong currents. The ACM is a preferred habitat for several key predator-prey relationships (NOAA, 2017). Ecological processes within the ACM are driven by tidal flux and riverine hydrology. Remedial technology assignments for the ACM designate and integrate into remedies for riverbank-contaminated sediments with special consideration to the ACM.

The following descriptions provide an overview of ACM conditions from the Habitat Conditions Survey Report (Appendix J of the PDI ER; HGL, 2024).

2.1.2.1 Characterization of the ACM

The ACM along SIB is divided into the following types that align with the "Habitat Characteristics" column in Table 1-1 baseline conditions in the column "Pre-RA Area (acres)":

- Sloped (<5H:1V or 11°), unarmored and vegetated (native) – 0.0 acres

[4] Riverbank transects are shown on Figure 2-1 "Habitat Conditions Survey Transects" in PDI ER Appendix J Habitat Conditions Survey Report.

- Sloped (<5H:1V or 11°), unarmored and vegetated (invasive) – 0.96 acres
- Sloped (>5H:1V or 11°), unarmored and vegetated (native) – 0.01 acres
- Sloped (>5H:1V or 11°), unarmored and vegetated (invasive) – 0.87 acres
- Sloped (<5H:1V), unarmored and unvegetated – 2.65 acres
- Sloped (>5H:1V), unarmored and unvegetated – 1.05 acres
- Riprapped – 5.60 acres
- Suspended structures over channel margins (e.g., docks) – 0.45 acres
- Floating structures (e.g., docks) – 0.01 acres

Suspended structures within the SIB ACM are summarized in Table 2-1. In addition to the suspended structures, much of the tip of Swan Island, at the mouth of SIB, is formed with a sheet pile bulkhead and an overlying pile-supported wharf, and the sheet pile and wooden retaining walls beneath the wharf structure extend into the ACM. The Quay Wall, at the northeastern tip of Swan Island, extends to OLW and is generally lacking an ACM.

2.1.2.2 Extent of the ACM

The ACM types in the SIB Project Area encompass 11.61 acres as modeled in the HEA. The acreages were estimated using field observations and GIS mapping reported in the baseline habitat survey included in the Habitat Conditions Survey Report (Appendix J of the PDI ER; HGL, 2024) and updated by the GIS spatial analysis applied to the Pre-Final 90% RD to develop inputs to the HEA model.

2.1.2.3 General Conditions

The ACM is highly variable throughout the SIB Project Area. It is generally described as dramatically simplified by heavy rock armoring and sparse vegetation when closely associated with industrial activity and moorage. Overwater structures obscure some of the most degraded channel margins. The steep, armored ACM slopes cover over 5 acres of the SIB shoreline.

Conversely, approximately half of the ACM (5.54 acres) can be described as relatively unarmored and in a more “natural” condition, albeit lacking structural complexity in wood, vegetation, and topography. Underlying substrate current conditions along the Swan Island shoreline are predominantly sandy loam, while underlying substrates along the Mocks Bottom shoreline are predominantly silt loam. The beach area at the head of the basin is composed of sand. Baseline and post-RA substrate conditions in the ACM are accounted in the HEA with acreage values reported in Table 1-1. Surficial substrates within the unarmored areas of the ACM are composed of gravel and sand in the lower elevations transitioning to riverbank soils in the upper elevations of the ACM.

2.2 BASELINE IN-WATER AQUATIC HABITAT CONDITIONS

In-water shoreline habitat units for this analysis comprise two principal physical units:

- Shallow Water Habitats
- Deep Water Habitats

In addition, two in-water habitat ecohydrological influences are considered:

- Water Quality
- Habitat Access

2.2.1 Shallow Water Habitat

Shallow water habitats are considered important for juvenile salmonids, because they provide food resources (benthic macroinvertebrates, zooplankton, and emergent insects) and refuge from predators in the main river. Although juvenile outmigrants may occupy the entire river, sub-yearling salmonids are expected to migrate close to the water surface and near the shoreline during rearing (within a few meters of the shoreline at water depths of less than 1 meter) (NMFS, 2005). Reducing current often associated with shallow water habitat provides an additional benefit to juvenile fish by significantly reducing their energy requirements. Because these small juveniles have relatively weak swimming capabilities, feeding is most effective in areas where current velocities are slow. Water velocities of 30 centimeters per second (cm/s) or less are considered best for optimal foraging opportunities (Bottom et al., 2001).

Shallow water habitats also play an important role in providing refugia habitats. Refugia habitats provide spatial and temporal resistance and resilience to aquatic-dependent organisms by sheltering them from impacts of natural and anthropogenic disturbances and offering opportunities for predator avoidance. In SIB, shallow water areas occur along the riverbanks and at the head of the basin, areas outside of the limits of maintenance dredging.

2.2.1.1 Extent

Shallow water areas encompass 22.79 acres of SIB based on data developed from a unified elevation model that integrated multiple data sources including light detection and ranging surveys (HGL, 2024) and refined for the 90% RD. While shallow water habitat areas are not static but change with the rise and fall of river height (flow) and tidal period, for this habitat evaluation, the shallow water area in SIB includes the area from the ACM lower edge (OLW [+7.3 ft NAVD88]) to a maximum depth of 20 ft below OLW (-12.7 ft NAVD88 [Figures 1-1a through 1-1f]).

2.2.1.2 General Conditions

Due to the industrial use of the SIB waterway and shoreline, shallow water habitat is extremely limited on the tip and most of the northeastern side of Swan Island. The most prevalent shallow water habitat in SIB occurs at the head of the basin, outside of the areas within the basin that are used for activities related to commercial vessels. Shallow water habitat also occurs along much of the Mocks Bottom shoreline of SIB in various conditions depending on the level of adjacent industrial development and ongoing activity. Baseline conditions for surficial substrates present in the shallow water habitat areas are predominantly natural substrates composed of gravel, sand, and silt. Some shallow water areas have derelict piling, and debris is present on the surface. Table 1-1 shows the changes in shallow water substate conditions that will result from the RA. Post RA shallow water substrates will include beach mix where slopes are flatter than 3H:1V (11.43 acres) and riprap on submerged slopes steeper than 3H:1V (9.30 acres). These areas and substrate types are incorporated into the HEA model.

2.2.2 Deep water Habitat

The way fish use deep water habitats may include rearing and migration with juvenile salmonids primarily foraging on zooplankton. Although ocean-type salmonids (i.e. sub yearling Chinook) may temporarily occupy these habitats, they are believed to prefer shallow-water habitat for rearing and migration. Deep water habitat is used primarily by those life phases that are more pelagic transitional, stream-type (yearling), and juveniles and adult salmonids from all species.

The deep water area includes the area of SIB with depths greater than 20 ft below OLW (HGL, 2024). This area's location is not static but changes with river height (flow) rise, fall, and tidal period. In SIB, deep water occurs in the basin interior and around dry docks and other dock areas where maintenance dredging occurs.

2.2.2.1 Extent

Deep water areas occupy 95.66 acres of the SIB Project Area as reported on Table 1-1. The reported extent of the deep water areas is based on defining deep water as areas of SIB with depths greater than 20 ft below OLW. While this definition yields a static deep water area of 95.66 acres for the HEA model, actual deep water acreage will vary based on river stage fluctuations.

2.2.2.2 General Condition

Much of the SIB is maintained as deep water to support the industrial uses of the waterway. Sediment evaluations conducted as part of the PDI (HGL, 2024), have determined that SIB sediments are predominantly soft mud with a relatively low bulk density, even at depth. Suspended structures, pilings, and dolphins are prevalent in deep water areas closer to the shoreline, where needed to support industrial activities or remnants of past industrial uses.

2.3 HABITAT SCORES FOR PRE-REMEDIAL ACTION BASELINE CONDITIONS

Habitat scores were assigned to the habitat types defined for the HEA model by NMFS and published in the RDGC, Appendix B, Table B-9. The areas for each habitat type were determined using spatial data (e.g., topography, bathymetry) in the Pre-Final 90% RD drawing set. The scores for each habitat type were determined using data published in the PDI ER pertaining to baseline habitat conditions, the riverbank conditions survey, and surface sediment data.

Table 1-1 shows the resulting habitat scores for pre-RA baseline conditions. The relatively low habitat scores reflect the generally degraded condition of most habitat within the SIB Project Area. Specific habitat degradation that strongly affected the scores includes the following:

- extensive and widespread invasive plant species within the riparian areas and ACM;
- widespread riprap and other forms of bank armoring on the riverbanks and in the ACM;
- derelict piling within the ACM and shallow water zones;
- shoreline and overwater structures.

Figures 2-1a through 2-1f illustrate the habitat areas and their baseline (pre-RA) scores within the SIB Project Area. Areas for each habitat type are reported on Table 1-1.

Figure 2-2 presents an infographic overview of substrates considered in the HEA. For the purpose of the HEA, rounded gravel "beach mix" and sand/silt placed as finished surface materials are considered natural substrates per EPA guidance (EPA, 2021b). Angular rock (e.g., riprap) placed as slope revetment, erosion protection layer, or other surface stabilization is considered an artificial substrate, and areas with those surface treatments are assigned a zero habitat score.

3.0 IMPACT ANALYSIS

The impact analysis applies the HEA model to compare post-RA habitat conditions to pre-RA baseline habitat conditions within the SIB Project Area. Post-RA habitat conditions used in this analysis are based on the final surface conditions specified in the Pre-Final 90% RD. Key considerations for determining HEA scores for post-RA habitat conditions include the following.

- **Vegetation conditions** – higher scores are assigned to areas with native vegetation rather than invasive species or unvegetated areas.
- **Slopes within the ACM** – higher scores are assigned to areas within the ACM that are sloped less than 5H:1V compared to slopes steeper than 5H:1V.
- **Riprap/Armor** – the presence of riprap or other bank armoring yields a score of 0.
- **Substrate** – natural material surface sediments yield a better score compared to sediments that are armored (e.g., riprapped) or adjacent to shorelines that are armored or protected by a seawall. For the purpose of the HEA, EPA considers beach mix and clean sand to be natural substrates. Riprap and armoring are not natural substrates.
- **Structures** – the presence of shoreline and overwater structures decreases the habitat score.
- **Piling** – the presence of piling results in a 50 percent reduction in the habitat score in affected areas.

The HEA incorporates the effects of time into the habitat scores related to impacts and habitat improvements. Time is incorporated and considered in the following ways:

- Duration of temporary construction impacts;
- Effects of ecological benefits and impacts in perpetuity; and
- Time required after RA completion for post-RA habitats to reach full ecological function.

In the Pre-Final 90% RD, the estimated RA construction duration is 9 years, with all in-water work adhering to in-water work periods (i.e., "fish windows") applicable within the Lower Willamette River. Temporary impacts are reduced through construction sequencing that limits active construction to discrete portions of the SIB Project Area. Construction duration is among the largest drivers of habitat impacts calculated by the HEA. The SIB RD Team plans to discuss potential ways to minimize impacts through adjusting the construction schedule. In the context of impact avoidance and minimization, potential adjustments to in-water work periods should be considered as a way of shortening the construction duration and associated ecological impacts.

The following sections discuss each of the habitat zones and the attributes considered in assigning habitat scores for the post-RA habitat conditions.

3.1 RIVERBANK ACTIONS AND IMPACTS

Riverbanks for purposes of this analysis include the riparian area and the ACM extending from the top of the riverbank to the lower ACM (+7.3 ft NAVD88). As reported in the PDI ER (HGL, 2024), soils within almost the entirety of the riverbanks and ACM within the SIB Project Area have concentrations of ROD contaminants of concern that exceed cleanup levels and many exceeding remedial action levels. Therefore, the majority of the riverbanks and ACM will require active remediation to meet Remedial Action Objectives (RAOs) across the entirety of the SIB Project Area. Remediation of the riverbanks and ACM will require removal of most existing vegetation, removal of existing bank armoring, removal of contaminated soil, and placement of clean material as a soil cover or cap depending on contaminant concentrations. Reapplication of heavy bank armoring (including riprap) is limited to locations that cannot be stabilized by bio-engineered design (i.e., bank surface stabilization using living native plant material, soil, and natural fiber erosion mats integrated to support plant establishment and long-term stability provided by the native plant community).

3.1.1 Riparian Area

This HIE evaluates impacts to the riparian area defined as the riverbanks located between the top of the riverbank and OHW (+20.1 ft NAVD88). Existing habitat conditions within the riparian area are dominated by invasive species plants and ubiquitous riprap or other forms of armoring and debris. Riverbank slopes above elevation +8 NAVD88 (which includes a portion of the ACM) will be planted with native vegetation as a final surface condition in locations where armoring is not required to resist wave erosion, protect infrastructure, or achieve geotechnical stability. The conversion of existing degraded riparian areas to native plant communities without riprap or armoring significantly improves the post-RA habitat conditions scores assigned to those riparian areas.

3.1.2 Active Channel Margin

The Pre-Final 90% RD specifies placement of an engineered cap within much of the ACM. In accordance with habitat requirements stipulated in the ROD and detailed in the RDGC, final surfaces for caps within habitat zones will be composed of a “beach mix” natural substrate composed of gravel and finer material. Compliance with seismic design requirements determined that rock revetment (angular rock) was required to ensure stability of slopes steeper than 3H:1V. The impacts of rock revetment placement in the ACM are accounted in the HEA model. Where beach mix is placed, the natural substrate will improve habitat conditions compared to existing portions of the ACM that contain riprap, other armoring, debris, or piling. Additionally, the proposed final grades within the ACM maximize the total area with slopes equal to or flatter than 5H:1V, which also improves the habitat scores assigned to those areas. Riverbank slopes above elevation +8 ft NAVD88 will be planted with native vegetation as a final surface condition in locations where armoring is not required to resist wave erosion, protect infrastructure, or achieve geotechnical and seismic stability.

3.2 AQUATIC IMPACTS

3.2.1 Shallow Water Habitat

The Pre-Final 90% RD specifies a combination of dredging and capping within the shallow water habitat zone to achieve RAOs. Similar to the remedial approach for the ACM, final surfaces for caps

within this habitat zone will be composed of a "beach mix" natural substrate composed of gravel and finer material less than 2.5 inches where feasible. On slopes steeper than 3H:1V, rock revetment (angular stone) is required to comply with seismic design requirements and ensure cap stability. Implementation of the RA will increase the extent of rock revetment within the shallow water habitat zone compared to baseline conditions. Larger aggregate at OLW within toe slope key material will vary in size depending on the steepness of the upper slope to both stabilize the slope and to provide wave dissipation. This approach complies with habitat requirements stipulated in the ROD and detailed in the RDGC. The natural substrate will improve habitat conditions compared to existing portions of the shallow water habitat zone that contain riprap, other armoring, debris, or piling. In the Pre-Final 90% RD, most shallow water slopes are proposed to be graded/filled to a minimum of 2.5H:1V, a slope expected to provide stability of smaller stream gravel material. The extent of riprap and other armoring within the shallow water habitat zone is much less compared to the riverbanks. Because this habitat zone is less degraded by riprap as a baseline condition, there is less potential ecological improvement available within this zone compared to opportunities within the riparian areas and ACM. While implementation of the RA will result in a net impact to the shallow water habitat zone, the design minimizes that impact by specifying a natural substrate (beach mix) where feasible.

3.2.2 Deep Water Habitat

The Pre-Final 90% RD specifies a combination of dredging and capping within 100 percent of the deep water habitat zone located within SIB. The final surface specified in the Pre-Final 90% RD will be the surface of the cap, which is an erosion resistance layer where needed and a biological layer (i.e., clean sand) where erosion protection is not required to protect the integrity of the cap. There is little opportunity to improve habitat conditions within the deep water habitat zone because nearly all of that zone already has a riverbed composed of low gradient slope sand and silt, which is considered to be a natural substrate (Figure 2-2). As a result, the strategy for this zone is to minimize further degradation by maximizing the area where the design specifies natural substrate materials for the final surface layer. The Pre-Final 90% RD reduced impacts to the deep water habitat zone by incorporating cap designs with a sand surface layer. The sand surface layer is applied consistently throughout the deep water habitat zone in two forms: (1) in areas subject to greater erosive forces, the cap design includes an erosion resistance layer composed of angular rock and topped with a layer of sand, and (2) in areas subject to lesser erosive forces, the cap design includes a thicker surface layer of sand that will provide erosion resistance by maintaining a dynamically stable condition. "Dynamically stable" means that temporary episodic scour can occur during a vessel transit, but the depth of scour is shallow enough, episodic, and not cumulative such that the chemical isolation layer at depth is protected. On submerged slopes flatter than 3H:1V, beach mix is sufficiently stable to resist erosion and provide a natural substrate. For slopes greater than 3H:1V, angular rock revetment is necessary to ensure geotechnical stability and comply with seismic design requirements. Habitat scores assigned to deep water habitats were determined primarily by the final surface material specified in the design, which reflects effective minimization of impacts to deep water habitats.

3.3 IMPACT DETERMINATION

A comparison of the individual and composite habitat scores for pre-RA baseline conditions and post-RA conditions as anticipated by the Pre-Final 90% RD is presented in Table 1-1. Habitat scores based

on the HEA methodology[5] were assigned to all habitat areas within the SIB Project Area for a total area of 139.17 acres, which includes both the in-water and riverbank portions of the Project Area. The HEA incorporates changes from pre-RA to post-RA habitat conditions and the variations in habitat score over time related to duration of construction and the time required for post-RA habitats to reach full ecological function (ranges from 0 to 5 years). The HEA score reflecting the post-RA habitat conditions and construction sequence/schedule envisioned by the Pre-Final 90% RD is -36.41DSAYS.

That HEA result considers the combined effects of RA habitat impacts; impact avoidance, minimization, and mitigation integrated into the RD; and the variability of habitat function over time in response to RA construction duration and the time required for post-RA habitat conditions to reach full function. The negative DSAY score indicates that the remedy as designed is not "self-mitigating" and will require additional compensatory mitigation for impacts to Waters of the U.S. and to Threatened and Endangered Species. Design modifications implemented between Pre-Final 90% RD and Final 100% RD may also contribute to improving the HEA score and reducing or eliminating the need for additional compensatory mitigation. Figures 3-1a through 3-1f illustrate the habitat scores assigned to habitat units for post-RA conditions. Figures 3-2a through 3-2f illustrate the HEA scores for post-RA conditions for habitat units within the SIB Project Area. Figures 3-2a through 3-2f illustrate that most of the net improvement in habitat conditions documented by this evaluation will be achieved within the riparian areas and ACM. It is notable that while opportunities to improve habitat conditions within the deep water zone are limited, the Pre-Final 90% RD minimizes impacts by applying sand material as a finished surface instead of the angular rock previously specified in the Draft 50% RD.

Unavoidable net impacts to shallow water habitat are included in the HEA analysis and drive the resulting negative DSAY score and need for compensatory mitigation. Those impacts are not associated with the "cap on grade" area at the head of SIB. The impacts are related to steep riverbanks extending to steep submerged slopes within the ACM and shallow water habitat zones along portions of Mocks Bottom and Swan Island shorelines. The estimated 9-year RA construction duration and the associated temporary construction impacts also contribute to the negative DSAY score suggesting that further impact reduction may be achieved through reducing construction duration. The SIB RD Team will discuss possible adjustments to in-water work periods as a component of reducing construction duration and reducing ecological impacts of RA implementation. The need for additional mitigation was anticipated and provided for in the ROD and RDGC as an allowable alternative to a "self-mitigating" remedy when such impacts cannot be practicably avoided.

The RD seeks to minimize further degradation within the shallow water and deep water habitat zones by limiting the extent of armor placement while specifying natural substrates on the finished leave surface wherever feasible without compromising the protectiveness and effectiveness of the remedy. Between the Draft 50% RD and the 90% RD, the design evolved to develop a cap solution for deep water habitats that provides a natural substrate instead of an erosion resistance layer composed of angular rock. Other notable design refinements reflected in the Pre-Final 90% RD include placement

[5] EPA published the HEA methodology in the Remedial Design Guidelines and Considerations (EPA, 2021a), Appendix B, Topic 9 "Habitat Mitigation." EPA distributed a HEA spreadsheet template to the SIB RD Team on May 20, 2025; an updated version of the HEA spreadsheet template that incorporated bug fixes was distributed on August 14, 2025.

of rock revetment (instead of beach mix) within the ACM and shallow zones on slopes greater than 3H:1V. That placement is necessary to ensure slope stability for seismic design requirements.[6,7]

The negative HEA score of -36.41 DSAYs indicates that the RA will need to include additional compensatory mitigation sufficient to address this score deficit. Two types of mitigation options are considered:

1. **On-site Mitigation** – the Pre-Final 90% RD incorporates feasible and practicable avoidance, minimization, and mitigation as integrated components of the SIB Project Area RD. After receiving EPA comments on the Pre-Final 90% RD, the SIB RD team will explore the potential for additional habitat mitigation in conversation with EPA.

2. **Mitigation Bank Credit Purchase** – mitigation bank credit purchase is allowed by the ROD and the RDGC. There are four existing mitigation banks that have service areas that include the PHSS. The SIB RD team contacted the operators of the Alder Creek Restoration Area mitigation bank located on the southern tip of Sauvie Island to request information about available and anticipated credit inventory and the estimated cost of credits measured in DSAYs. As of July 25, 2025, the Alder Creek Restoration Project has 487 DSAY credits available for sale and approximately 190 DSAY credits that will be released for sale in the future. The quoted pricing is $62,000 per DSAY. That information is confirmed in a web post by the Portland Harbor Natural Resource Trustee Council (2024). Dialogue with EPA and perhaps coordination with NMFS will be needed to confirm that the mitigation bank DSAY credits are suitable to apply to the HEA model calculated DSAY deficit characterizing impacts to Waters of the U.S. and impacts to Threatened and Endangered Species.

The specific mitigation proposal will be completed as part of the preparation of the Final 100% RD. If mitigation opportunities prove infeasible or impracticable, sufficient mitigation bank credit inventory is available to mitigate for the HEA score DSAY deficit calculated for the Pre-Final 90% RD post-RA conditions.

[6] Geotechnical Design Technical Memorandum (Volume I, Appendix I), Section 3.2 Seismic Design Parameters states, "The design-level earthquakes considered include the Contingency Level Event (CLE) and the Design Earthquake (DE), consistent with EPA and USACE guidance for critical infrastructure. The CLE is defined in the RDGC (EPA, 2021a) while the DE is based on ASCE 61-14 and ASCE 7-22."

[7] In a coordination meeting including EPA and the SIB RD Team on July 24, 2025, EPA indicated that there is some flexibility in the application of the seismic design guidance presented in the RDGC.

				Total	**139.17**	**139.17**		**(36.41)**

Notes:
[1] achieves 80% of full function within 10 years; this time is adequate because of flood protection
[2] cannot be created
The credit for simply removing pilings is limited to 0.1 and for removing covering structures is limited to 0.5.

< = less than; > = greater than; ° = degrees
sf = square feet
CRD = Columbia River Datum
DSAY = Discounted Service Acre Years
El = elevation
OHW = ordinary high water
OLW = ordinary low water
NA (n/a) = not applicable
NAVD88 = North American Vertical Datum of 1988
RA = Remedial Action
SIB = Swan Island Basin
TOB = top of [river]bank

Notes:
1. Remedial Design Guidance and Considerations (EPA, 2021) indicates that for habitat impact evaluation, rounded gravel (beach mix) and clean sand/silt placed as finished surface materials are considered natural substrates.
2. Angular rock used as slope revetment. Erosion resistance layer, or surface stabilization is not considered a natural substrate and receives a zero habitat score in the Habitat Equivalency Analysis.

RIVERBANK DESIGN TECHNICAL MEMORANDUM

This page was intentionally left blank.

RIVERBANK DESIGN TECHNICAL MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
REMEDIAL DESIGN SERVICES, SWAN ISLAND BASIN PROJECT AREA
CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

1.0 INTRODUCTION

This Riverbank Design Technical Memorandum (RDTM) presents a summary of the design basis and design criteria for riverbanks in the Swan Island Basin (SIB) Project Area for the Pre-Final 90% Remedial Design (RD). The Pre-Final 90% RD is conducted for the SIB Project Area within the Portland Harbor Superfund Site (PHSS) in Portland, Multnomah County, Oregon. The HydroGeoLogic, Inc. (HGL) team performed the work on behalf of the SIB RD Group based on the requirements of the PHSS Record of Decision (ROD) (EPA, 2017) and the Administrative Settlement Agreement and Order on Consent (EPA, 2021). The data used in the riverbanks design analyses were collected in accordance with the final Pre-Design Investigation (PDI) Work Plan, which the U.S. Environmental Protection Agency (EPA) approved in May 2022 (HGL, 2022) and were reported in the PDI Evaluation Report (ER), which the EPA approved in January 2025 (HGL, 2024a).

Section 2.0 of this RDTM describes the location and physical condition of riverbanks in the SIB Project Area, discusses Remedial Action Objective (RAO) 9, introduces the groundwater modeling memo, and describes the purpose of the riverbank remedial action (RA). Erosion, geotechnical, and habitat information that informs the riverbank remedial technologies selection and basis of the remedy design are summarized in Section 3.0. Section 4.0 presents riverbank design criteria. Attachment A to this RDTM provides a detailed description of the groundwater modeling performed to aid in the design of the riverbank RA. Attachment B provides the flood impact evaluation performed based on the details of the 90% RD, and Attachment C provides the details of the design of the chemical isolation layers (CILs) for riverbank areas.

2.0 EXISTING RIVERBANK INFORMATION AND DESIGN AREA

This section presents a description of the physical condition of SIB Project Area riverbanks, information on the extent of contamination, description of the RAO for PHSS riverbanks, and a summary of the habitat impact evaluation conducted for the SIB Project Area as it relates to the riverbanks.

2.1 PHYSICAL CHARACTERIZATION

SIB is bordered by approximately 2.3 miles of riverbanks bounded by uplands of Swan Island and Mocks Bottom to the southwest and northeast. The SIB Project Area encompasses riverbanks that extend from the top of bank (TOB), which varies in elevation within different portions of the SIB,

CORPORATE HEADQUARTERS
11107 Sunset Hills Road, Suite 400
Reston, Virginia 20190
703-478-5186

to mean high water (MHW) or +13 feet (ft) North American Vertical Datum of 1988 (NAVD88). Existing riverbank slopes in the SIB Project Area range from vertical walls (structures) and steep banks (e.g., steeper than 2.5H:1V) to gradual shoreline. These slopes are presently and predominantly armored with riprap and/or protected from erosion by dense vegetation, bulkheads or other shoreline structures. The shoreline at the head of the basin consists of a beach and boat ramp area. The Mocks Bottom shoreline is more vegetated than the Swan Island shoreline, which is primarily marine industrial facilities.

2.2 PRE-DESIGN INVESTIGATION INFORMATION

The PDI was conducted to perform visual assessments of riverbank conditions and to address data gaps. The physical conditions information collected provided information for the bank stability analysis, and soil samples collected from TOB, ordinary high water (OHW) mark, and at or below the mean low water (MLW) elevation provided detailed nature and extents of ROD contaminants of concern (COCs).

The visual assessment revealed the extent of shoreline development, varying slopes, erosion protection, erosion prone areas, and marine structures extending over and beyond the riverbanks. Features limiting riverbank access include 23 shoreline structures with limited access beneath adjacent to open land areas at TOB. Soil sampling and chemical analyses results indicate the presence of COCs including arsenic, mercury, polychlorinated biphenyls (PCBs), dioxin/furans, pesticides, and bis(2-ethylhexyl)phthalate. Soils containing concentrations of COCs exceeding ROD Table 17 cleanup levels (CULs) are widespread in surface and subsurface (limited dataset to 3 ft below ground surface [bgs]) soil samples (HGL, 2024a). To evaluate riverbank erosion, visual inspection and light detection and ranging (LiDAR) elevation data were analyzed for existing erosional features.

Bank Erosion Hazard Index (BEHI) model ratings indicate erosion probabilities range from low to extreme. Near Bank Stress (NBS) ratings which indicate erosion potential were calculated to be low for all riverbank transects analyzed (HGL, 2024a). Riverbank erosion conditions are discussed further in Section 3.2.

Section 6.6.6 of the ROD (EPA, 2017) includes remediation of contaminated riverbanks to protect the in-water remedy. Beyond the ROD-specified remedial riverbanks, additional areas were added for RD based on the PDI ER finding of widespread contamination in SIB Project Area riverbanks exceeding CULs contiguous with the Sediment Management Area.

2.3 GROUNDWATER INFORMATION AND MODELING

Though the discharge of impacted groundwater is not an identified concern for the SIB Project Area, the presence of riverbank soils with COC impacts above CULs warranted consideration of groundwater discharge through the riverbanks as a potential pathway for contaminant migration. The SIB RD team compiled and reviewed all available groundwater data within the vicinity of the Project Area and geological/stratigraphy information to provide an understanding of groundwater behavior in the SIB Project Area.

Attachment A provides a technical memorandum describing the information available and used to create and fit a two-dimensional numerical groundwater model that provides an understanding of the groundwater movement in the SIB Project Area.

Information from this model was used, in part, to determine the sediment cap and riverbank seepage scenarios that were used in the 90% RD analyses. Section 3.4.3 describes the chemical isolation design that was informed by the groundwater model.

2.4 REMEDIAL ACTION OBJECTIVE

The CULs for riverbank soil are presented in ROD Table 17 (EPA, 2017). The CULs are long term contaminant concentrations that need to be achieved to meet the RAO to reduce migration of COCs in riverbanks to sediment and surface water such that levels are acceptable for human health and ecological exposure (RAO 9). Based on the PDI results for COCs exceeding CULs, significant long term erosion potential for most of the SIB Project Area riverbanks require RA. In addition to CUL exceedances, concentrations of COCs exceeding ROD Table 21 remedial action levels (RALs) and principal threat waste (PTW) thresholds are prevalent throughout the riverbanks and must be remediated in accordance with ROD Figure 28 (EPA, 2017).

The design considerations and remedial technologies to be implemented for the RA to address the physical condition and extent of contamination to achieve the RAO are discussed in Sections 3.0 and 4.0 of this RDTM.

2.5 HABITAT IMPACT EVALUATION SUMMARY

The Habitat Impact Evaluation (HIE) Technical Memorandum (Volume I, Appendix C) uses a Habitat Equivalency Analysis (HEA) model to evaluate the net ecological benefits or impacts of RA implementation according to the Pre-Final 90% RD. The HEA model provides a structured framework for evaluating the ecological effects of RA implementation on Waters of the U.S. and on threatened and endangered species and their habitats within the SIB Project Area. The HIE informs remedial design by identifying specific places and surface treatments that avoid or minimize impacts or provide ecological benefits that mitigate for unavoidable impacts. Specific effects on riverbank design decisions considered and incorporated into the Pre-Final 90% RD are summarized below:

- Establish native riparian vegetation on riverbanks to the maximum extent feasible and practicable without compromising attainment of the RAO.
- Place natural materials (e.g., sand or beach mix, topsoil) on final grades within the riparian, active channel margin, shallow water, and deep water habitat zones.
- Remove derelict piling and related structural members from in-water and shoreline areas.
- Remove riprap, debris, and seawalls wherever feasible and practicable within the riparian, active channel margin, and shallow water zones.
- Limit the installation of new rock revetment to situations where it is required to maintain cap integrity by resisting erosive forces and ensuring geotechnical and seismic stability.

- Establish final grading within the active channel margin (ACM) and shallow water with slopes flatter than 5H:1V.

The HEA quantitatively considered the benefits and impacts of RA implementation across the range of habitats present within the SIB Project Area and determined there would be a deficit score reflecting a need for additional compensatory mitigation to make up for unavoidable impacts of the remedy and mitigation options are being considered for development between the Pre-Final 90% RD and the Final 100% RD.

3.0 RIVERBANK DESIGN CONSIDERATIONS

This section describes the approach to the RD for achieving RAO 9 for SIB Project Area riverbanks, including existing land use, ecological value, erosion, groundwater seepage, and geotechnical stability. The resulting design incorporated these considerations to produce remedial technology assignments.

3.1 REMEDIAL DESIGN TO ACHIEVE THE REMEDIAL ACTION OBJECTIVE

The portions of the SIB Project Area at and above the upper boundary elevation of the shallow water zone (+13 ft NAVD88) are considered riverbanks. A number of evaluations of the SIB Project Area riverbank conditions and applicable remedial technologies were used to develop design criteria for completing the riverbank RD.

The RD addresses the ROD requirement to evaluate riverbank slopes across the SIB Project Area to understand localized impacts on remedial activities. The RD addresses recontamination risk associated with erosion of contaminated riverbank soil through a combination of soil remediation and riverbank stabilization. The RD accomplishes these objectives using multiple components:

- Removal of a layer of riverbank soils (thickness varies by location);
- Providing a chemical barrier to seepage-based migration of dissolved COCs;
- Placement of vegetation or rock armoring surface treatment, to protect the barrier treatment layer; and
- Long-term monitoring of riverbank areas to assure a protective remedy.

The RD was completed to incorporate the placement of a CIL as the long-term barrier to any incidental migration of COCs from riverbank soils and to prevent CULs exceedances in downgradient surface water and sediment (described in Section 3.4.3). Vegetative covers or rock armoring (depending on location and driven by existing land use and geotechnically stable grades) provide physical protection of the CIL. Institutional Controls will guide and restrict disturbance of riverbanks, while long-term monitoring of shoreline conditions and requisite maintenance will ensure continued remedy effectiveness.

The construction details for riverbank work are presented in the CAPPING, SHORELINE PROTECTION AND OUTFALL SCOUR PROTECTION drawings (Volume III, Appendix V). Sheets CA100-CA301 provide the plans and sections of the excavation of riverbank soils,

placement of materials, and planting areas to address areas that have COC concentrations above RALs and PTW thresholds of the riverbank.

The ROD applies multiple considerations and requirements that have guided the determination of final slope, composition, and surface treatment (e.g., riprap, shoring, soil bioengineering, native vegetation). The riverbank design must transition continuously to the ACM and in-water remedy elements with respect to both remedial objectives and ecological requirements and considerations. The RD approach to riverbanks involves removing, grading, and placing material on existing riverbanks, with a focus on maintaining stability both above and below the water level. Significant portions of the existing riverbank slopes are only marginally stable, and slope reconfiguration or stabilization measures will be required to achieve the RAO.

As described in Section 4.3 of this RDTM, the RD incorporates ecological features. As a result, the riverbanks will be finished with native vegetation communities where such treatment is precluded by shoreline structures, steep slopes that require engineering stabilization, or requirements of the property owner or facility operation.

3.2 EROSION EVALUATION

The PDI ER included completion of a bank stability analysis using the BANCS model including BEHI and NBS determinations (Rosgen, 2001; 2014). The BEHI is a procedure for assessing potential stream bank erosion conditions. The riverbank erosion analyses are presented in the PDI ER Appendix D, Riverbank Characterization Data Report (HGL, 2024a). Existing riverbanks in the SIB Project Area are erosive and unstable and require active remediation to prevent additional erosion and recontamination of the in-water areas due to both hydraulic instability (wind-waves, boat wakes, rainfall runoff), and geotechnical instability (global slope stability, surficial material stability).

3.3 GEOTECHNICAL STABILITY

The ROD (EPA, 2017) highlights the necessity of evaluating the geotechnical stability of slopes throughout the SIB Project Area. This assessment is essential for understanding the localized impacts on the design and implementation of remedial activities.

The existing riverbanks are currently marginally stable, with localized areas of instability. The riverbank reconnaissance conducted during the PDI noted multiple areas of surficial soil movements (HGL, 2024a). Slope stability analyses have been undertaken for the existing and proposed remedial condition and reported in the GDTM (Volume I, Appendix I). The results of the stability analyses confirmed that the existing slopes will require reconfiguration as part of the RD. The aim of the reconfiguration is to flatten the slopes to a stable angle, while limiting the impact on the shoreline and overwater structures. This reconfiguration is significantly responsible for the geometry of the RD of side slopes in SIB. The additional fill to be placed for this reconfiguration of slopes has been evaluated within a hydraulic (“no-rise”) analysis of the water surface elevation within SIB, as presented in the Flood Impact Evaluation Technical Memorandum, included as Attachment B.

The recommended maximum slope gradients for the Pre-Final 90% RD range between 2.5H:1V and 2.75H:1V for both temporary and permanent unreinforced slopes. Detailed stability evaluations and design recommendations are provided in the Geotechnical Design Technical Memorandum (GDTM; Volume I, Appendix I). Areas of the side slopes of the SIB below MHW are addressed with capping, and the details of that design are presented in the Cap Design Technical Memorandum (CDTM, Volume I, Appendix E).

3.4 REMEDIAL TECHNOLOGY ASSIGNMENTS

The remedial approach presented in this section utilizes technology assignments for the SIB Project Area riverbanks consistent with the Technology Application Decision Tree as seen in ROD Figure 28 (EPA, 2017). Riverbank guidelines were further refined in the Remedial Design Guidelines and Considerations (RDGC), Appendix D, Figure 4 (EPA, 2025) which contains the *Decision Guide for Characterizing and Implementing Remedial Action for ROD Riverbanks*.

Drawing sheet CA107 presents the plan view of the resulting RD for the CIL protection covers.

3.4.1 Excavation and Grading

Excavation of the riverbanks is intended to be performed as needed for proper construction of bank remediation. Most areas require an initial removal effort for clearing and grubbing, which entails removal of surface materials such as vegetation, debris, and existing riprap. The depth of the excavations vary, depending on the location with the SIB and the elevation on the riverbank. In general, the goal is to develop a smoothly graded slope over which the CIL and armored bank protection or planted areas can be constructed.

The geometric/topographic design of the slopes of riverbanks is governed by static and seismic geotechnical stability, navigation depth considerations at the bottom of the slope (below the riverbanks), the presence of in-water structures, and efficient material use. Stability of the structures and slopes was evaluated according to criteria in the RGDC (EPA, 2021b) and is presented in the GDTM (Volume I, Appendix I). Over the vast majority of the SIB Project Area, the proposed riverbank slope (after remediation) is similar to the existing slope. In these areas, only limited excavation is proposed in some areas to smooth the slope into the design slope from the toe of slope to TOB. Samples will be collected from these riverbank soils at the completion of the excavation work in these areas. These slopes typically require modest backfill in some areas as well, resulting in minimal net excavation. Excavated material with COC concentrations exceeding the CULs cannot be re-used on-site. However, if excavated material is shown to not have CUL exceedances, it could be reused as fill in the RA.

On the Swan Island shoreline, roughly between the Wind Tunnel and Lagoon Wharf, the existing slope is over-steepened and requires flattening to achieve the static and seismic slope stability guidelines in the RDGC. Therefore, in these areas, backfill with imported materials (or excavated material from the riverbank, if it does not contain CUL exceedances) is required after an initial clearing and grubbing effort to remove vegetation and surface debris that represent an undesirable foundation for the slope materials.

3.4.2 Backfill Materials

Imported backfill is required to support bank reconstruction. The structural backfill will consist of clean, angular materials with geotechnical properties (as described in Technical Specification Section 31 00 00) that allows proper compaction and slope performance.

For underwater applications (below the riverbanks), backfill will be placed using a well-graded stone with a D50 between 1 and 3 inches. These materials will be required to limit fines contents, with less than 5 percent (%) passing the No. 200 sieve. Backfill in these areas will follow the general gradation and material quality standards of the Oregon Department of Transportation (ODOT) Standard Specifications 00330.15. Where structural fill is needed for overwater infrastructure, material selection and placement will conform to ODOT Specification 00510.13.

3.4.3 Chemical Isolation

Riverbank areas were sampled as part of the Pre-Design Investigation (PDI), and soil concentrations presented in Table 1-3b of the CDTM (Volume I, Appendix E) show RAL or PTW threshold exceedances from samples collected within each of the future 30 Riverbank Certification Units (RCUs) in the SIB Project Area. Based on Figure 4 of the *Guidelines for Riverbank Characterizations and Evaluations at the Portland Harbor Superfund Site* (RDGC, Appendix D), RCUs will be remediated per ROD Section 14 and design requirements in 14.2.9 (EPA, 2025).

All riverbank areas will be remediated with a CIL placed on the smoothly graded slope, after excavation and backfill placement. The CILs vary in type, depending on the location and land use of the riverbank.

3.4.3.1 Extents of CILs

All riverbank areas have CILs that extend down to the MHW elevation. The upper limit of the extent of the CIL placement for an area depends on the potentiometric conditions of SIB. As described in the groundwater modeling memo (Attachment A), groundwater potentiometric elevations vary, depending on the river stage. Though higher elevations of the riverbank will experience much less potential seepage of groundwater than the bottom sediments of SIB (due to the total time throughout a year that the riverbank experiences different river surface elevations), the stratigraphy and hydraulic conductivity of riverbank soils may allow exfiltration of groundwater from the banks as high as 2.4 ft of vertical elevation above OHW on the Mocks Bottom riverbank slopes. The CIL extends to +22.5 ft NAVD88 from the south corner of SIB (Outfall S2) and all riverbank areas to the northeast and north-northwest (head of the basin and Mocks Bottom slopes).. However, riverbank areas on the Swan Island side of SIB experience much less upgradient groundwater head, and so the CIL extends only to +20.5 ft NAVD88 on riverbanks from the southern-most corner (Outfall S2) west-northwest around the Swan Island portion of the Project Area through the Berth 312 area.

3.4.3.2 Compositions of CIL Evaluated for Riverbank Design

For riverbank areas that are steep grades (steeper than 3H:1V) and around structures, rock revetment is used as the surface treatment. For these areas, a reactive core mat (RCM) CIL will be

placed beneath the stone. The RCM is a geocomposite product that includes an absorbative core composed of activated carbon (AC), sandwiched between geotextile components. The RCM CIL was evaluated for conservative modeled conditions for seepage rates on riverbanks where vegetation will not be drawing down soil moisture through evapotranspiration. The evaluation of the RCM CIL is provided in the CDTM (Volume I, Appendix E) under Selected Constructable Alternatives F and G.

For the remainder of the riverbank areas, a vegetative cover (described in Section 4) will be placed, providing ecological value, a physical barrier to COCs within the riverbank soils, mitigation of potential seepage through evapotranspiration, and long-term protection from erosion. Underneath the vegetative cover, the CIL was designed to be an effective barrier to the migration of dissolved contamination, should groundwater levels produce conditions of seepage from the riverbanks. This vegetative cover CIL comprises a mixture of clean, imported topsoil with 3 percent by weight imported biochar, which is moderately compacted within a cellular confinement system for construction. The requirements of the construction of this topsoil/biochar CIL are detailed in Specification Section 31 32 16 Topsoil Chemical Isolation Layer for Riverbanks (Volume III, Appendix U).

The performance of this CIL at preventing the migration of COCs within groundwater seepage was evaluated using CapSIM, as described in Attachment C. The combination of the CILs and cover systems is described below.

3.4.4 Constructable Alternatives of Riverbank Covers

The CDTM presents the process of assigning selected constructible alternatives for capping areas. Riverbank areas armored with rock layers were similarly assigned cover systems based on minimum alternative protectiveness. Selected constructible alternatives for rock-armored slopes are:

- **Selected Constructible Alternative F**: 0.8 inches (2 centimeters [cm]) of Tektoseal-AC with overlying 3 ft (90 cm) of stone protection system in revetment zones, including 2 ft (60 cm) of armor and 1 ft (30 cm) of bedding stone.
- **Selected Constructible Alternative G**: 1.6 inches (4 cm) of Tektoseal-AC with overlying 3 ft (90 cm) of stone protection system in revetment zones, including 2 ft (60 cm) of armor and 1 ft (30 cm) of bedding stone.

Riverbanks remediated and replanted with vegetation were assigned:

- **Selected Constructible Alternative H**: 12 inches (30.5 cm) of topsoil and biochar mixture with an overlying 24 inches (61 cm) of topsoil, planted according to the habitat types of the ecological design (Section 4).

Bank erosion protection is achieved using a combination of rock revetment in the more energetic areas with steeper slopes, up to elevation +20 ft NAVD88 (OHW). In a few steeper areas, rock revetment is required to extend to top-of-slope. The Design Drawings (Volume III, Appendix V) detail the particular areas addressed by the riverbank covers.

However, the vast majority of the SIB Project Area riverbank includes planted vegetation as the bank stabilization for areas above elevation +20 ft NAVD88.

In areas flatter than 3H:1V and in the low energetic areas predominantly found at the head of SIB, habitat mix (less than 2-inch rounded gravel) serves as erosion protection for the sediment cap and extends from deeper water up to elevation +13 ft NAVD88 on unplanted slopes. Habitat mix will extend to +9.4 ft NAVD88 on planted slopes at the lower elevation of wetland vegetation communities.

Planted areas include lifts of soil bags wrapped in coir fabric (Envirolok or similar) to provide elevation gain and facilitate insertion of flatter areas (minimum 3H:1V, or flatter) above each lift for planting. The lifts themselves are erosion resistant in the short term, due to the bags and coir fabric wrap. In the long term, roots and woody vegetation will provide structural support and erosion resistance. The planted areas will be covered in jute netting or similar to protect the topsoil during initial plant growth.

Figure 3-1 shows the alternative assignments for riverbanks throughout the SIB Project Area.

4.0 RIVERBANK ECOLOGICAL DESIGN CRITERIA

4.1 TOP OF BANK TRANSITION

Upland areas immediately beyond the SIB Project Area boundary (TOB) are largely developed with existing features such as buildings, vertical wall structures, paved/gravel parking areas and access roads, perimeter/security fences and maintained lawn areas. Efforts have been made in the riverbank design to preserve/protect existing structures and minimize disturbance of paved/gravel areas and lawn areas. However, to excavate and construct revetment keys at the TOB for construction of maximum slopes necessary for riverbank stabilization, the disturbance of existing pavement, gravel and lawn areas and removal of existing fencing will be required in some areas where unavoidable. In these cases, the in-kind restoration of these existing features is proposed at the same line and grade as the pre-existing conditions. Therefore, there will be no change in existing stormwater runoff patterns resulting from riverbank stabilization/improvements.

4.2 EROSION CONTROL DURING REMEDIAL ACTION CONSTRUCTION

Temporary erosion control is required to minimize the erosion of excavated/smoothed slopes into SIB during construction, prior to permanent bank protection and planting. Erosion control measures consist of soil logs and similar erosion best management practices placed at the top of slope to minimize flow down the banks. It is not anticipated that the slope will require a complete soil cover throughout the temporarily excavated/smoothed condition.

The RA Contractor will be required to develop a design for a temporary erosion control (TESC) plan. Requirements for that TESC Plan are addressed in Specification Section 31 25 00 Erosion and Sedimentation Control. The TESC Plan to be prepared by the RA Contractor will include best management practices and engineering controls to manage the effects of erosion during active construction on the riverbanks.

4.3 HABITAT TYPES AND LOCATIONS

4.3.1 Reference Condition

The re-introduction of native habitat elements is often centered on the characterization of pre-development conditions which guide design elements. This is done because the common habitat restoration directive is to restore at least a part of natural habitat conditions that once existed prior to human disturbance. However, the SIB Project Area has been manipulated since the late 1800s (HGL, 2024b). Historically, the Project Area was an active riverside habitat with overbank marsh that was once part of the active channel of the Willamette River and connected to a low elevation active floodplain (Mocks Bottom). Industrialization of the Project Area disconnected the area from the flow of the river, converting SIB into a backwater lagoon that is armored and disconnected from the historic floodplain. Therefore, it is infeasible to recreate the pre-disturbance, riverine ecology that once existed. Instead, the habitat elements considered for the Project Area are intended to enhance the existing ecological function of a quiescent backwater refuge with a diverse riparian riverbank. Two nearby freshwater tidal wetland areas that have a backwater slough present were selected for identifying reference conditions. One is Oaks Bottom (USFWS, 1981) which is approximately 7 miles upstream of SIB on the Willamette River. The other is Government Island (USFWS, 2009) approximately 8.5 miles as the crow flies and approximately 12 miles upstream of the confluence of the Willamette and Columbia Rivers.

4.3.2 Current Condition

The current condition of SIB Project Area riverbanks discussed in this section are the segments that are exposed and not under, or immediately adjacent to, existing marine infrastructure. All areas of riverbank that are covered by infrastructure are underlain by weathered riprap.

The conditions that now exist along exposed riverbanks within the SIB Project Area exhibit the characteristics of a tidal wetland in the lower elevations of the riverbank and transition to woody riparian vegetation within the upper banks. The Project Area experiences tidal cycles from which varies the daily water level over a range of 3 ft to 4 ft with a maximum range of approximately 6 ft (HGL, 2024a).

A key characteristic of the tidal conditions and species selection within tidal wetland communities is the range of salinity, particularly during lower water levels when a wedge of ocean waters can propagate upstream. Salinity within SIB was determined to vary between 0.04 and 0.05 parts per thousand (ppt). In freshwater tidal wetlands, the salinity of the oligohaline zone (the low salinity zone, before transitioning to nontidal riparian communities), is typically less than 0.5 ppt. Salinity at SIB is a tenth of the salinity necessary for even a low salinity zone; therefore, SIB is characterized as freshwater.

The lower elevation of portions of the riverbanks is sloped at gradients of 20% (1H:5V) or less. During a 1%-chance flood event, the riverbanks are exposed to maximum shear stresses less than 0.5 Pascal and wave heights typically less than 1.5 ft.

Existing vegetation on the riverbanks is sparse. Most established plants are invasive species such as Himalayan blackberry, English Ivy, and Scotch broom. A stand of mature black cottonwood

grows on a strip of the upper bank of the southwest corner of the basin; however, most trees are not considered healthy, and the understory is mostly invasive vegetation. Details of habitat conditions are described in the Habitat Conditions Survey Report (PDI ER, Appendix J, HGL, 2024a).

The SIB Project Area riverbanks have the capacity to support vegetation communities ranging from tidal freshwater marshes at the wetted shoreline to tree-dominated riparian communities above the ordinary high water line.

4.3.3 Habitat Goals

In addition to the primary goal of reducing migration of COCs in riverbank to sediment and surface water such that levels are acceptable in sediment and surface water for human health and ecological exposure (i.e., achieving RAO 9), applicable or relevant and appropriate requirements (ARARs) further shape the riverbank design in the SIB Project Area in terms of habitat goals. Table 4-1 summarizes the ARARs and other criteria that have been applied to the riverbank habitat design.

Table 4-1 Habitat Goals Related to ARARs

Goal	Related ARAR
Establish viable refuge for ESA-listed fish species	ARAR: OAR 635 100 0135 – Incorporate preferred habitat for federally-protected species ARAR: Magnuson Stevens Fishery Conservation and Management Act – Minimize impact on essential habitats ARAR: ESA – Minimize impact on essential habitats *Other: Yakama Nation – Recover ESA-listed and tribally important species*
Connect lagoon habitat with river	*Other: Yakama Nation – Develop continuum of habitat ("string of pearls, series of stepping stones")*
Create self-sustaining, native riverbank vegetation	*Other: Yakama Nation – Functioning ecosystem; riparian vegetation*
Establish diversity of tidal freshwater wetlands	TBC: EO 11990 – Incorporate nascent wetlands *Other: Yakama Nation – Create off-channel habitat, restore wetlands* *Other: Yakama Nation – Diversity of nearshore shallow habitat (large wood, diverse shallows)*

Notes:
EO = Executive Order
ESA = Endangered Species Act of 1972
OAR = Oregon Administrative Rules

The primary habitat goal met by the RD's proposed riverbank topography is to increase marsh area elevations where the river hydrology supports hydrophytic vegetation (between mean daily low water during growing season or +9.4 ft NAVD88 to +15.4 ft NAVD88). Wherever possible, the slopes within these freshwater tidal elevations have been designed as 5H:1V or less to create maximize the area that supports hydrophytic wetland vegetation.

4.3.4 Native Riparian Vegetation Communities

The following lists the habitat types that will be placed from the upper extent of shallow in-water region to TOB throughout the Project Area. The placement of the habitat types is guided primarily

by the vertical elevation and the associated hydroperiod (each vertical area is outlined in Table 4-2) with adjustments applied horizontally to account for localized site conditions such as stormwater outfalls, groundwater seeps, and proximity to infrastructure.

Table 4-2 Vertical Habitat Zones

Habitat Type	Vertical Zone	Description
Riparian vegetation community – Riparian Tree/Shrub	TOB to OHW	This area will be dominated by trees and shrubs where trees are proposed only in this upper portion of the riverbank. An important consideration for this zone is to allow for proper growth of tree roots.
Palustrine Scrub Shrub	Upper portion of the ACM from MHW to OHW	This scrub-shrub community is a transition between the woody species above OHW and the herbaceous marsh species at the wetted shoreline. The mature height of species in this habitat zone is not expected to exceed 20 ft.
Riparian vegetation community –Tidal Freshwater Wetland Marsh	The typically wetted portion of the ACM (between mean high and mean low water)	This community is proposed for portions of the riverbank where the upper shallows are a minimum of a 5H:1V slope or flatter. This community would include obligate herbaceous species in lower elevations and facultative species in the transition to the scrub-shrub habitat.
In-water Large Wood, Beach mix	Below MLW	Large wood pieces not including treetops or root wads placed on the riverbank to provide cover and foraging for fish. All large wood pieces are placed low on the bank toe and within shallow water zones to ensure submergence throughout most of the year.

A key parameter to species survival is the frequency of water at root depth. The water table changes not only in elevation but seasonally, and in response to the tidal flux. Therefore, the statistic frequency of the water surface is a critical determinant to bound the vertical extents of the vegetation communities. Figure 4-1 charts the frequency that elevations on the riverbank are expected to be submerged, particularly during the growing season. This submergence frequency directly guides the selection of species for elevations on the bank and where transitions between communities are expected.

An important characteristic of the vegetation communities is that they are not bound by a firm demarcation but rather that species plantings emphasize transitions between habitat types. This creates a diverse habitat as well as allow for plant communities to develop along a transitional gradient adaptable to site conditions.

4.3.4.1 Tree/Shrub, Riparian Vegetation Community

This area is a mix of riparian shrubs and trees that are composed of pioneering and long-term species. This area, which is above the OHW mark but below the TOB, is a fractional introduction of a riparian community. The transitional zone shown in Figure 4-2 illustrates the role that this community is expected to occupy in the Project Area. The shrubs and trees planted in this area will provide the vital root matrix and shade to the lower tidal wetland (shown as the “toe zone” and “bank zone” in Figure 4-2). The “overbank zone” depicts a riparian bench that, if not present in this area, will result in the ecological community lacking a natural connection to a mature upland

(the "upland zone") that can provide a diverse seed source. Therefore, the species selection for this community include a diverse understory to introduce a vibrant, self-sustaining community.

4.3.4.2 Considerations Regarding Tidal Freshwater Wetland Marsh

The design will create tidal freshwater wetland marsh community, designated at the wetted shoreline. Marsh vegetation is not currently observed in the Project Area. It is, however, a vegetation community commonly found along natural tidally influenced freshwater shorelines with low gradients. The absence of marshes at the present in the SIB Project Area is likely related to multiple factors, including the ecologically young lagoon environment, bank armoring, steep gradients that reduce the area for wetland species to establish, and dominance of invasive species.

4.3.5 Plant Palette and Rationale

The plant list for the SIB Project Area riverbank habitat design is presented in Table 4-3, attached at the end of this memorandum. This table provides the species selected for planting to establish the habitat communities described below. The species included in this table meet the guidelines specified in the Willamette Greenway Plan referenced in the City of Portland code for greenway landscape planning (Title 33, Chapter 33.440, referred to as the "Greenway Code"). This chapter was also referenced to establish the minimum densities of trees and shrubs included in the plant list. For nearly all communities, plant design densities will exceed those outlined in the Greenway Code to ensure natural clustering and to counter anticipated mortality.

The existing native tree species that were identified in the SIB Project Area above OHW (HGL, 2024a) were contrasted with the plant communities from the Portland Plant List (City of Portland, 2016) as specified in the Greenway Code. The applicable plant communities the existing SIB Project Area native species belong to include Western Hemlock Doug Fir Forest, Mixed Coniferous/Deciduous Riparian Forest, Deciduous Forested Wetlands and Floodplains, and Scrub-Shrub Wetlands. These plant communities are the target plant communities for the riparian planting area. The tree species selected are dominant in the plant communities listed above, present in the SIB Project Area or the Oaks Bottom reference site and are commercially available in the Portland area. A minimum of one tree will be planted every 20 ft of river frontage (required by the Greenway Code) across the hydrologic elevation gradient from TOB down to the lower elevation wetland areas.

The shrub dominant plant community, including scrub-shrub wetland areas will be located below OHW down to MHW or to the geotextile chemical isolation barrier limits. These species were selected based on their presence in the scrub-shrub wetland plant community (City of Portland, 2016), as well as presence in the upper elevation plant communities to be able to adapt and be a seed source throughout the Project Area, their presence at the reference site, and common use in Pacific Northwest tidal restoration projects, as well as commercial availability in the Portland area. Shrubs will be minimally planted every 25 square ft of the intended riverbank community, as required by the Greenway Code.

In areas with geotextile CIL, plant species will be limited to herbaceous plant species with fine roots rather than woody species.

The herbaceous emergent marsh plants will be primarily located below MHW and were predominantly selected based on presence in marsh and scrub-shrub plant communities, hydrophytic wetland indicator status, presence at the reference site, and commercial availability in the Portland area.

4.3.6 Key Design Elevations

The habitat types that will exist in three primary zones are defined by elevation and the relative access to the water level. These habitat types are: shallows, ACM, and upland riparian riverbank to the TOB Project Area boundary extent. Table 4-4 defines the elevations that demark the vertical extents of vegetation communities. The elevations are not considered to be a strict boundary, but rather to identify vertical extents on the riverbank where habitat types transition from one to another and maximum species overlap is expected.

It's important to emphasize that, while the water elevation within SIB is technically sloped from the head to river confluence (draining from the head to the mouth of the basin), the difference is sub-inch. Therefore, for planting considerations, it is assumed that SIB is a flat surface and design elevations are applied equally throughout the Project Area.

4.3.7 Riverbank Substrate and Subgrade Layering

In areas where slope flattening is not required, the riverbanks will be cleared and grubbed to a minimum depth of 18 inches to remove invasive species and armor layer. Grain-size analysis of subsurface soil samples collected during the PDI (HGL, 2024a) indicate that the subgrade media is composed of mostly fine-grained soils, predominantly silty sand or sand with clay that is suitable for vegetation subgrade.

Reference soil conditions indicate silt loam soils predominate in the top 5 ft of analogous wetland reference sites (NRCS, 2025). Reference soils indicate organic matter (OM) content of 1% to 4% in the top 15 inches and 0.5% to 2% in the top 5 ft. Portland area, naturally-occurring wetland soils have an average of 10% OM in the top 2 inches (range of 1% to 45%) and 6% to 7% in the top 12 inches (Schaffer and Ernst, 1999). OM content of 10% is also common for the top 12 inches of newly planted areas to help plants establish. Over time the OM will travel down through the soil profile as water infiltrates and carries with it the OM.

The proposed planting soil medium is 10% OM for the top 12 inches and 2% to 3% OM from 12 to 24 inches. Below 24 inches, soil substrate would be composed of either native soil, an imported backfill made up of predominantly fine-grained soil similar to existing subsoils, or biochar mixed in with soil, as discussed in Section 4.3.8.

Table 4-4
Key Elevations for Defining Approximate Boundaries of Riverbank Vegetation Communities
Riverbank Design Technical Memorandum, Swan Island Basin Project Area, Portland Oregon

Elevation (ft NAVD88)[1]	Vertical Habitat Area	Vegetation Community (Elevation range in ft NAVD88)	Significance	Rationale and Sources
TOB[2]	Riparian	Riparian Tree/ Shrub (TOB to +20)	Upper extent of Project Area Boundary	"River banks are defined as the area from the top of bank down to the river." ROD, Section 6.6.6 (EPA, 2017)
+20	ACM	Scrub-Shrub +20 to +15.4	OHW	USACE, Portland-Vancouver Harbor Information Package, 3rd Ed, Table A-2. OHW for Willamette. All of lower Willamette River assigned 16.6' NGVD as OHW (20.04 NAVD88, NOAA vertical datum transformation). Guidance for Riverbank Characterizations. PHSS, Figure 3; references PHSS RI, App A3, Table A3-5, Footnote b: "An elevation of +20 ft NAVD88 (ordinary high water mark [OHWM]) is the upper edge of the riverbank (DEQ, 2003)."
+15.4	ACM	Freshwater Tidal Wetland +15.4 to +9.4	Submerged 10% during the growing season (March 1 to October 31)	In Regional Supplement to the USACE Wetland Delineation Manual: Western Mountains, Valleys, and Coast Region, wetland is defined where hydrophytic vegetation can grow and is submerged 10% of the growing season (Mar 1 – Oct 31). Elevation derived from Morrison Street gage water level data.
+13.0	ACM	N/A	***Upper extent of ROD "shallow region"*** MHW for PHSS	PHSS RI, App A3, Table A3-5, footnote a: An elevation of +13 ft NAVD88 (mean high water mark [MHWM]) is the elevation defining the shoreline boundary of the PHSS. This elevation is based on a DEQ memorandum dated July 9, 2003 to EPA regarding the upland/in-water boundary for the Superfund site (DEQ, 2003). Figure 3 of the Guidelines for Riverbank Characterizations and Evaluations at the Portland Harbor Superfund Site (EPA, 2025) uses +13 ft NAVD88 as the MHW elevation, revised from the 2019 version of the same document that used +10.14 ft NAVD88.
+12.0	ACM	N/A	Mean daily high water (USGS gage)	MHW level from USGS gage at Morrison Bridge. The mean daily high water and mean daily low water have been observed to be the typical boundaries for herbaceous marsh vegetation.

Table 4-4
Key Elevations for Defining Approximate Boundaries of Riverbank Vegetation Communities
Riverbank Design Technical Memorandum, Swan Island Basin Project Area, Portland Oregon

Elevation (ft NAVD88)[1]	Vertical Habitat Area	Vegetation Community (Elevation range in ft NAVD88)	Significance	Rationale and Sources
+9.42	ACM	Ballasted Large Wood +7 to +9.5 Beach mix +9.5 to +3.28	Mean daily low water during growing season. Lower extent of wetland plant community.	MLW level calculated using water level data from USGS gage at Morrison Bridge that included only measurements recorded during the growing season between March 1 and October 31.
+7.28	Main Channel	N/A	**OLW [design final].** MLW datum, Morrison Bridge tidal station.	From updated EPA guidance (-Email ref-), because a formal survey of OLW was not performed for PHSS, the tidal MLW is an acceptable determination of OLW.
+5.1	Main Channel	N/A	OLW, initially reported in ROD	OLW was stated in the Final Portland Harbor Programmatic EIS and Restoration Plan, App B Lamprey Monitoring Plan, Section "Restoration project sites" (page B-5) Lamprey will be monitored in off-channel wet areas and areas that are deeper than OLW (5.1 ft NAVD88) at each restoration project site. Also referenced in Habitat Impact Evaluation; source: Anchor QEA, 2012, PH RI/FS, Draft Mitigation Framework (not yet found). Riverbank observations of vegetation and assessment of submergence frequency indicate that +5.1 ft is underwater nearly 100% annually.
+3.28 (-2 CRD)	Main Channel	N/A	Lower extent of ROD "Shallow Region"	Defined in ROD, 14.2.4 Shallow Region, page 108: The shallow region is defined as shoreward of the riverbed elevation of approximately -2 ft CRD. -2 CRD converted to +3.28 NAVD88 using NOAA Vertical Datum Transformation. The NMFS declaration of the extent of shallow water (below) is determined to override this initial ROD determination, and then redefined again in guidance for performing Habitat Equivalency Analysis.
-2.7	Main Channel	N/A	Shallow water, 10 ft water depth	Shallow water 10 ft depth as defined by depth below MLW (El 7.28 – 10 ft = El -2.7).

Table 4-4
Key Elevations for Defining Approximate Boundaries of Riverbank Vegetation Communities
Riverbank Design Technical Memorandum, Swan Island Basin Project Area, Portland Oregon

Elevation (ft NAVD88)[1]	Vertical Habitat Area	Vegetation Community (Elevation range in ft NAVD88)	Significance	Rationale and Sources
-9.72 (-14.92 CRD)	Main Channel	N/A	Lower extent of shallow water by NMFS definition for Portland Harbor	ROD, Tribal Comment/Response 3.1.78: "NMFS defines shallow water as above -15 feet CRD and EPA is coordinating with NMFS to ensure consistency."
-12.7	Main Channel	N/A	Shallow water, 20 ft water depth	Shallow water 20 ft depth as defined by depth below MLW (El 7.28 – 20 ft = El -12.7).

Notes:
[1] Elevation values shown in **bold** and highlighted in color are key elevations that define riverbank design elements. Elevations in plain text are provided for informational or historical context.
[2] TOB elevation is not a specific datum but a morphological feature where the riverbank slope breaks to the flat upland surface.

GROUNDWATER DISCHARGE MODELING TECHNICAL MEMORANDUM

GROUNDWATER DISCHARGE MODELING TECHNICAL MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
SWAN ISLAND BASIN PROJECT AREA, CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

This Groundwater Discharge Modeling Technical Memorandum presents a summary of modeling performed to evaluate groundwater-surface water exchange at the Swan Island Basin (SIB) Project Area within the Portland Harbor Superfund Site (PHSS). Specifically, the elevation at which groundwater discharges to SIB above the surface water stage was calculated to support the Remedial Design (RD). The data used in this evaluation were collected in accordance with the final Pre-Design Investigation (PDI) Work Plan, approved by the U.S. Environmental Protection Agency (EPA) in May 2022 (HGL, 2022) and were reported in the PDI Evaluation Report (ER), approved by EPA in January 2025 (HGL, 2024a). In addition to PDI data, data sources used in this evaluation included Willamette River stage data (USGS, 2025), topographic and bathymetric data (OLC, 2019; USACE, 2010), impervious surface data (USGS, 2024), and groundwater and lithologic data from area investigations (Brown and Caldwell, 2008; Snyder, 2008; GSI and SSPA, 2020).

Section 1 presents an overview of the conceptual site model (CSM). Section 2 details model development. Section 3 details model fitting and sensitivity analyses performed. Section 4 presents the model results and uncertainty analyses. Section 5 includes discussion and recommendations. Section 6 provides a list of references used in the generation of this technical memorandum.

1.0 CONCEPTUAL SITE MODEL OVERVIEW

The following section presents an overview of the SIB Project Area CSM, specifically related to groundwater hydrology. A more comprehensive CSM is provided in the Basis of Design Report (Section 2; HGL, 2024b).

1.1. PROJECT AREA

The PHSS extends along 9.9 miles of the lower Willamette River in Portland, Oregon, from river mile (RM) 1.9 to RM 11.8. The SIB Project Area is the active cleanup area between approximately RM 8.1 and RM 9.2 on the northeast side of the Willamette River (HGL, 2024a). The SIB Project Area is approximately 1.1 miles in length, 117 acres in size, and includes riverbanks that extend up to the top of the bank (Figure 1-1).

1.2. TOPOGRAPHY AND BATHYMETRY

The SIB Project Area is bounded by the uplands of Swan Island and Mocks Bottom to the southwest and northeast, respectively. Except for the slopes along the riverbanks, the land surface of Swan Island and Mocks Bottom is generally flat, with elevations of about 35 to 45 feet (ft) National Geodetic Vertical Datum of 1988 (NAVD88). The land surface rises rapidly from about

Corporate Headquarters
11107 Sunset Hills Road, Suite 400
Reston, Virginia 20190
703-478-5186

45 ft NAVD88 to about 170 ft NAVD88 at the top of Willamette Bluff (Figure 1-2). Willamette Bluff, also referred to as Mocks Crest bluff or the Willamette Escarpment, was formed when the Willamette River incised primarily fine-grained silts deposited during catastrophic flooding during Pleistocene time (Gannet and Caldwell, 1998; Woodward et al, 1998). As a result, there is a transition from primarily silt to alluvial deposits in the Willamette River floodplain (Beeson et al., 1991; Brown and Caldwell, 2008).

SIB was historically part of the main channel of the Willamette River, and Swan Island was not connected to the shoreline area of Mocks Bottom. The main navigational channel was relocated to the west side of Swan Island in approximately 1932, and SIB was formed when sediments from dredging a new channel were used to connect Swan Island to Mocks Bottom (HGL, 2024b). The bottom elevation of SIB ranges from approximately -3 ft NAVD88 at the southeast to -30 ft NAVD88 at the northwest (Figure 1-2) based on a bathymetric survey performed in 2022 (Appendix E of PDI ER, HGL, 2024a).

Figure 1-2 presents a continuous topobathymetric digital elevation model (DEM) that was generated for the SIB Project Area (as well as Mocks Bottom and Swan Island) by combining the 2019 1-meter Light Detection and Ranging (LiDAR) based DEM (OLC, 2019) compiled from The National Map downloader provided by the U.S. Geological Survey (USGS) with the 2022 bathymetric survey, coarsened to a 1-meter DEM, for locations where the 2019 DEM elevations were less than 7 ft NAVD88 (corresponding to locations slightly above the 2019 DEM surface water elevation). Locations below 7 ft NAVD88 where bathymetric survey data was not available (due to inaccessibility primarily resulting from docks, piers, and ships) were filled using elevations from the 2010 Lower Columbia Digital Terrain Model (USACE, 2010).

1.3. HYDROLOGIC SETTING

The Portland, Oregon area received an average of 45.6 inches of rain per year between 2012 and 2024 (NCDC, 2025). Precipitation occurs primarily between October and April. In the SIB Project Area, Mocks Bottom and Swan Island, precipitation is primarily directed towards stormwater infrastructure from impervious surfaces where it is discharged to SIB. Figure 1-3 depicts percent of impervious surface from the 2023 National Land Cover Database (USGS, 2024). Throughout the SIB Project Area and Mocks Bottom, impervious surfaces cover approximately 80 percent of the land surface.

1.4. GEOLOGIC SETTING

The SIB Project Area is located near the western edge of the Portland Basin, a northwest-trending structural basin bordered by the Tualatin Mountains (Portland West Hills) on the west and the foothills of the Cascade Range on the east. The Portland Basin is one of several structural basins filled with continental, sedimentary rocks of late Miocene, Pliocene, and Pleistocene age and underlain by older Eocene to Miocene volcanic and sedimentary rocks that crop out around the edge of the basin on the west, north, and east (Swanson et al., 1993). As the Portland Basin subsided, upper Miocene to Pliocene-age Sandy River Mudstone and Troutdale Formation were deposited across the Portland Basin, primarily by the ancestral Columbia River (Tsr and Tt in Figure 1-4) (Brown and Caldwell, 2008). The Sandy River Mudstone consists of primarily

siltstone, sandstone, and claystone. The overlying Troutdale Formation consists of conglomerates with minor interbeds of sandstone, siltstone, and claystone (Beeson, et al., 1991).

The Troutdale Formation was weathered and eroded during Pleistocene glaciation when sea levels were approximately 400 ft lower than present day (Brown and Caldwell, 2008). Periodic catastrophic glacial outburst floods during the late Pleistocene caused a series of as many as 40 colossal floods in the Columbia River (Swanson et al., 1993). These catastrophic floods from the periodic failure of ice dams impounding huge lakes in Idaho and Montana repeatedly scoured and then deposited both coarse- and fine-grained sediments in the Portland Basin up to an elevation of approximately 350 to 400 ft (Qfc and Qff on Figure 1-4) (Swanson et al., 1993; Brown and Caldwell, 2008).

Following the last catastrophic flood, sea level gradually rose to current levels resulting in the deposition of fine-grained alluvium consisting of interbedded silt and fine-grained sand within the historical Willamette River channel, scour channels, and tributary stream valleys that border the Willamette River (Qal on Figure 1-4) (Brown and Caldwell, 2008). Swan Island was originally formed as a sandbar of the Willamette River and has had artificial fill applied to raise the topography and connect it to Mocks Bottom (Qaf on Figure 1-4). Mocks Bottom is an infilled abandoned meander channel of the Willamette River consisting of finer-grained alluvium than Swan Island that also had its topography raised with the application of artificial fill (Appendix F of PDI ER, HGL, 2024a).

Artificial fill that covers Swan Island and Mocks Bottom above water level is generally composed of sand, gravel, and rock placed for building foundations (Appendix F of PDI ER, HGL, 2024a). Artificial fill was primarily sourced from Willamette River dredge sand when the main navigational channel was shifted to its current location southwest of Swan Island, but it also included timber dolphins, timber railroad trestles, timber dredge support structures, abandoned dredge pipes, abandoned drainage pipes, railroad embankment material, rip rap, retaining walls, logs, and wood debris (Brown and Caldwell, 2008).

1.5. HYDROGEOLOGY

Hydrogeologic units in the general location of the SIB Project Area within the Portland Basin have been mapped into four major units, depicted on Figure 1-4, which have been grouped into three subsystems: Older Rocks Subsystem discussed in Section 1.5.1, the Lower Sedimentary Subsystem outlined in Section 1.5.2, and the Upper Sedimentary Subsystem described in Section 1.5.3 (Appendix F of PDI ER, HGL, 2024a; Swanson et al., 1993). Section 1.5.4 discusses hydraulic conductivities.

1.5.1. Older Rocks Subsystem

Along the western boundary of the Portland Basin, the Older Rocks Subsystem consists of Columbia River Basalt (Tcr on Figure 1-4), which is used as an aquifer with large capacity wells penetrating several hundred feet of the unit to connect one or more interflow zones. Some wells completed in the Columbia River Basalt can produce over 1,000 gallons per minute; although, the capacity to store water is limited, resulting in water-level declines as a result of overdevelopment (Swanson et al., 1993).

1.5.2. Lower Sedimentary Subsystem

The Older Rocks Subsystem is overlain by undifferentiated fine-grained sediments that make up the Lower Sedimentary Subsystem. These fine-grained sedimentary rocks consisting of mudstone, siltstone, and claystone of the Sandy River Mudstone (Tsr on Figure 1-4) and occasionally the Troutdale Formation (where the Troutdale Sandstone Aquifer is not present) act as a confining layer between the Older Rocks Subsystem and the Upper Sedimentary Subsystem (Swanson et al., 1993).

1.5.3. Upper Sedimentary Subsystem

The consolidated gravel aquifer overlies the undifferentiated fine-grained sedimentary rocks of the Lower Sedimentary Subsystem and is composed of several geologic formations of poorly- to moderately-cemented conglomerate and sandy conglomerate of the Troutdale Formation (Tt on Figure 1-4). In some locations, thick accumulations of lavas and a mantling soil horizon are present. The consolidated gravel aquifer is an important and productive source of groundwater throughout the Portland Basin with yields between 50 and 1,000 gallons per minute (Swanson et al., 1993).

The consolidated gravel aquifer is overlain by the unconsolidated sedimentary aquifer consisting of catastrophic flood deposits of the late Pleistocene (Qff and Qfc on Figure 1-4) and alluvial deposits from the Columbia River and Willamette River (Qal on Figure 1-4) (Swanson et al., 1993). The catastrophic flood deposits of the late Pleistocene are sometimes referred to as the Missoula flood deposits because they are sourced primarily from the periodic draining of Glacial Lake Missoula and flooding of the Columbia River (O'Connor et al., 2001).

The unconsolidated sedimentary aquifer is the upper most aquifer present at the SIB Project Area, extending from ground surface to a depth of between 50 and 100 ft and consisting of alluvial flood deposits of late Pleistocene age varying from bouldery gravel to silt (Appendix F of PDI ER; HGL, 2024a). The uppermost unit has also been defined as the fill, fine-grained facies of flood deposits, and recent alluvium (FFA) unit that is composed of the fill, the combined fine-grained facies of the Pleistocene flood deposits, and the recent alluvium geologic units consisting of silt, clay, silty sand, and fine-to-medium sand (EPA, 2016).

1.5.4. Hydraulic Conductivities

Hydraulic conductivities for stratigraphic and lithologic units were described by Brown and Caldwell (2008) and EPA (2016). The units and hydraulic conductivities (or ranges) are presented in Table 1-1. Hydraulic Conductivities were not measured for all stratigraphic units or lithologic units present at the SIB Project Area. Notably, hydraulic conductivities for the artificial fill have not been measured.

1.6. GROUNDWATER

The elevations at which groundwater was first encountered near the SIB Project Area range from approximately 6 to 27 ft NAVD88. The FFA hydrogeologic unit of the Upper Sedimentary Subsystem is the primary unit of importance in defining interactions between upland groundwater and the Willamette River because the unit forms most of the river channel and surrounding upland

areas and, therefore, controls groundwater interactions (EPA, 2016). Continuous groundwater observations have not been made in the SIB project area to assess seasonal and tidal influences on groundwater elevations.

Within the FFA, the distribution of soil textures controls the horizontal and vertical groundwater flow. Generally, shallow groundwater from the upland area of Mocks Bottom flows toward SIB and the Willamette River, and discharges either above the river stage as seeps or below the river stage as subsurface discharge, generally in nearshore areas. Groundwater levels and fluxes in the shallow system are affected by seasonal river stage changes, as well as by diurnal tidal influences (EPA, 2016).

Groundwater elevations were measured in standpipe piezometers and via vibrating wire piezometers from 2006 through 2008 at five locations near the SIB Project Area as reported in the Portsmouth Force Main Geotechnical Data Report (Brown and Caldwell, 2008). Measurements from PMW-1-02A and PMW-1-06A, adjacent to the SIB Project Area, indicate that shallow groundwater elevations range from about 6 ft NAVD88 to 14 ft NAVD88 and fluctuate seasonally with lower elevations in late summer and higher elevations in spring (Figure 1-5). Measurements from PMW-1-09A (below Willamette Bluff), PMW-2-01R (just above Willamette Bluff), and PMW-2-02A (above Willamette Bluff) suggest that there may be a large groundwater gradient across the bluff from about 45 ft NAVD88 in PMW-2-01R to 18 ft NAVD88 in PMW-1-09A (Figure 1-5). However, groundwater elevations measured at PMW-2-02A suggest that the steep gradient may be dependent on the sampled interval. PMW-2-01R was sampled at an elevation of -17.4 ft NAVD88 via vibrating wire piezometer, while PMW-2-02A was sampled at an interval of -0.3 to 14.7 ft NAVD88, and PMW-1-09A was sampled at an interval of -1.8 to 13.2 ft NAVD88 via standpipe piezometers. Additionally, the bluff slope between PMW-2-01R and PMW-1-09A appeared to be underlain by fine-grained flood deposits with no observed groundwater seeps or springs along the slope; however, bluff slope soil exposures were limited (Brown and Caldwell, 2008).

Groundwater elevations at the Daimler Truck site in the northern portion of Mocks Bottom were collected in September 2019 from several monitoring wells. Groundwater elevations ranged between 16 ft and 26 ft (no specified vertical datum) (GSI and SSPA, 2020). Monitoring wells with higher recorded water elevations (23 to 26 ft) tended to be screened relatively shallow (5-ft screens from 10 to 20 ft below ground surface [16 to 30 ft elevation]). Deeper wells, screened at similar elevations to SIB had groundwater elevations between 16 ft and 20 ft (GSI and SSPA, 2020).

Direct seepage was measured in SIB using Ultraseep meters (US) and differential pressure piezometers. US measurements were collected from 16 locations within SIB and 5 locations at the mouth of SIB between July 12 and July 15, 2023. This date range was selected for monitoring to correspond with expected maximum annual groundwater upwelling to surface water (Appendix B of PDI ER, HGL, 2024a). Fifty-hour tidally-averaged specific discharges range from 0.218 centimeters per day (cm/d) immediately adjacent to the Mocks Bottom shoreline to -0.001 cm/d[1] at the southeastern end of SIB near the middle of the basin. Figure 1-6 presents the average, 50-hour rolling mean specific discharge at each station in SIB. Higher specific discharges were

[1] The negative value indicates a net *recharge* rate into the aquifer over the 50-hour average

generally observed closer to the shore along the Mocks Bottom (northern) side of SIB. Observations for specific discharge and vertical head gradient were used to develop vertical hydraulic conductivities along the bottom of SIB (Appendix B of PDI ER; HGL, 2024a). These station locations are also discussed in Section 3 (and shown on Figure 3-1).

1.7. SURFACE WATER

SIB is a lagoon that is backwatered from the main Willamette River Channel. Currents within the interior of the SIB move slowly over the range of flow conditions in the river, including flood events and daily tidal cycles. Daily tidal fluctuations are on the order of 3 to 4 ft, with a maximum range of approximately 6 ft (HGL, 2024a; HGL, 2024b).

The Willamette River is a major tributary of the Columbia River and flows into the river at Columbia RM 103, approximately 8 miles downstream from the SIB Project Area. The lowest water levels in the Willamette River typically occur between September and early November prior to influence from the seasonal rains in the region. Flow within the Willamette River generally increases in response to regional storms, with record winter flooding (e.g., 1964 and 1996) occurring when periods of heavy snowfall at lower elevations were followed by warming periods and heavy rains, resulting in rapid increases in runoff (EPA, 2016).

The Willamette River stage and SIB stage were assumed to correspond to the closest Willamette River gauge located at Morrison Bridge (approximately RM 13, 5 miles upstream of the head of SIB)[2]. The stage is reported relative to the gauge height of +1.55 ft National Geodetic Vertical Datum of 1929 (NGVD29). For consistency with recent elevation data for the area, reported using NAVD88 for the vertical datum, all stage elevations were converted from reported stage to NAVD88 by adding the gauge zero elevation (1.55 ft NGVD29) to get to NGVD29 and then converted to NAVD88 by adding 3.467 ft to Morrison Bridge measurement using the National Geodetic Survey (NGS) Coordinate Conversion and Transformation tool (NGS, 2025). The Willamette River stage recorded at Morrison Bridge during the SIB specific discharge monitoring from July 12 through July 15, 2023 is presented in Figure 1-7.

2.0 MODEL DEVELOPMENT

An averaged cross-sectional groundwater flow model was developed for the SIB Project Area and upland areas of Mocks Bottom using MODFLOW 6 Version 6.5.0 (Langevin et al., 2024) and Groundwater Vistas Version 9.12 (Environmental Simulations, Inc., 2024). A cross-sectional model was chosen to model average groundwater flow from the upland Mocks Bottom area to the SIB Project Area based on averaged values because detailed hydrogeologic data (e.g., boring logs, groundwater elevations, upland groundwater flux, and hydraulic conductivities) in the upland area was limited. The model was used as a calculator to estimate the upper elevation at which groundwater discharges to SIB under several Willamette River stages. The hypothetical cross-

[2] The next gauge downstream is located along the Columbia River at St. Helens (Columbia RM 85), approximately 26 miles downstream (NWPS, 2025a). The stage difference between the two gauges averages approximately 1 ft or 0.03 ft/mile. This results in an estimated Willamette River stage that is approximately 0.15 ft for the SIB Project Area.

sectional model was set up as a steady state model to simplify the modeling inputs and does not incorporate transient tidal effects or recharge from precipitation.

The hypothetical cross-sectional model was fit to observe groundwater discharges to SIB and incorporated as much site-specific data as was available (Section 3.0); however, required assumptions for modeling parameters result in inherent uncertainty. Both a sensitivity analysis (Section 3.0) and an uncertainty analysis (Section 4.0) were performed to assess the model fit and the potential variation in the estimated upper elevation that groundwater discharges to SIB.

2.1. MODEL GRID AND TOPOGRAPHY

Model properties were averaged within the hypothetical cross-sectional model from an area 2000-ft wide by 6080-ft long perpendicular to the Willamette River (Figure 2-1) to a model area comprising 5-ft by 5-ft grid cells that is one cell wide by 1,216 cells long. The modeled area was selected to approximately intersect the center of SIB in an area where the greatest concentration of specific discharge measurements were collected in July 2023. The modeled area also allowed the model grid to extend farther to the northeast while being entirely contained within Mocks Bottom. The southwestern extents of the modeled area were selected to correspond to roughly the center of the Willamette River, where the source of groundwater discharge to the river can likely transition from the northeastern bank to the southwestern bank. This assumption is reasonable when the watershed areas on both sides of a surface water body are similar with similar geologic formations. In this instance, the presence of the Portland West Hills and the edge of the Portland Basin may alter the location of the groundwater discharge divide.

The hypothetical cross-sectional model is composed of uniform, flat vertical layers that are 2 ft tall and extend from -100 ft NAVD88 to 46 ft NAVD88. Cells where the bottom elevation was above the cross-sectional average topobathymetric DEM elevation (parallel to SIB and the Willamette River) were set as no flow cells.

2.2. MODEL BOUNDARY CONDITIONS

The model used four types of boundary conditions: no flow boundaries, river boundaries, constant head boundaries, and, after model fitting, constant flux boundaries. Each exterior cell of the model was assigned one of these boundary conditions.

The top surface of the model was set to no flow boundaries corresponding to the cross-sectional average land surface (recharge was applied to the top active model cell). The right (southwest) and bottom model edges were also set to no flow boundaries corresponding to the convergence of flow from the northern and southern banks of the Willamette River at the center of the river. The left (northeast) model edge was set to no flow boundaries above an elevation of 2 ft NAVD88 (Figure 2-2). This was done to make the model more flexible when adjusting upgradient heads and prevent model errors from setting constant heads that are lower than the grid cell elevation. The bottom boundary was set to no flow, approximately corresponding to the Troutdale formation.

River boundaries were set in the cell immediately above the cross sectional average topobathymetric DEM surface in locations where the cell bottom elevation was less than 26 ft NAVD88 (Figure 2-2). Each river boundary cell was assigned a specified stage, riverbed vertical hydraulic conductivity, and riverbed thickness. The river stage was specified at 8.09 ft NAVD88

from the tidally averaged Willamette River Stage between July 12, 2023 at 1200 hours PDT and July 14, 2023 at 1400 hours PDT to correspond with the 50-hour tidally averaged specific discharge estimates (Appendix B of PDI ER; HGL, 2024a). The riverbed vertical hydraulic conductivity values were calculated from the tidally averaged vertical gradient and specific discharge at each monitoring location (Appendix B of PDI ER; HGL, 2024a).These values were averaged along seven SIB transects shown on Figure 2-3. Each transect was 80 ft wide to ensure that there was at least one observed value while maintaining the spatial variability of observations with distance from the shoreline. The averaged vertical hydraulic conductivity values were applied to each river cell within the model that intersected the transect. River cells that were not intersected by one of the transects were assigned an average vertical hydraulic conductivity from all calculated values from the July 2023 porewater upwelling investigation (Appendix B of PDI ER; HGL, 2024a). The riverbed thickness was assigned a uniform value of approximately 50 centimeters (~20 inches) based on the set midpoint penetration depth of the subsurface sediment probe for the Trident Probes (Appendix B of PDI ER; HGL, 2024a)

Constant head or constant flux boundaries were set on the left (northeast) edge of the model below and elevation of 2 ft NAVD88 (Figure 2-2). As discussed above, this was done to make the model more flexible when adjusting upgradient heads and prevent model errors from setting constant heads that are lower than the grid cell elevation. Constant heads were set to 18 ft NAVD88 for the initial modeling to fit the model to observed specific discharges in July 2023. An elevation of 18 ft NAVD88 was selected for these boundaries based on observed upland heads near the bluff, specifically at PMW-1-09A of about 18 ft NAVD88 (Figure 1-5) (Brown and Caldwell, 2008). An elevation of 18 ft NAVD88 may be similar to the deeper screened wells from GSI and SSPA (2020), although the vertical datum for the values in that report is unknown. The constant head elevation in the upland area of Mocks Bottom is uncertain and likely varies in response to upgradient precipitation and may include a perched zone within the artificial fill.

Once model parameters were fit, the constant head boundaries were changed to constant flux boundaries based on the calculated flux at each constant head boundary cell. This change was necessary when modeling different river stages to ensure that the potentiometric surface can respond appropriately without being fixed at the upgradient side; however, this approach assumes that the amount of flux from the upgradient boundary (Mocks Bottom) is constant.

Recharge was applied to the uppermost saturated model cell using an annual average recharge value. The annual average recharge to groundwater was estimated using a deep percolation model based on the annual average precipitation, percent impervious area, and the land surface elevation (Snyder et al., 1994; McFarland and Morgan, 1996). The maximum calculated recharge across the 2000-ft-wide modeled area was applied to each grid cell (Figure 2-4). Recharge was not applied over the area that intersected SIB or the Willamette River. The maximum recharge value was selected to account for areas where recharge is likely occurring because using the average recharge across the area results in zero recharge throughout the model except for a small section along the northeastern bank of SIB.

2.3. MODELED HYDRAULIC CONDUCTIVITY

A geological model was developed in Seequent Leapfrog Works (versions 2021 to 2024.1) to define the three-dimensional subsurface stratigraphy. The SIB Project Area geological model

represents a probable but unconfirmed and unverified, simplified model of geological conditions, based on a desktop study, the Geotechnical Data Report (Appendix F of the PDI ER; HGL, 2024a), and historical ground investigation data. There is a key assumption that the data used is factually correct and that generally accepted theories about the structure and stratigraphy of the local area are also correct. Gaps in the data exist, so interpretation and geological judgment were required to interpolate between known data points. Contradictions in data were also found to exist, thus selecting which data to incorporate and which to omit also required significant geological judgment. Interpolated strata boundaries are uncertain and approximate.

Leapfrog Works uses three-dimensional implicit modeling to provide fast and dynamic modeling of the ground conditions, including analysis of the interactions with the engineering design. Meshes are used to represent surfaces in the form of vertices and triangles that define the three-dimensional shape of the surface. Geological surfaces are typically developed from ground investigation point data that can then be advanced through geological interpretation controls within the software. The following delineated hydrostratigraphic units were modeled for the SIB Project Area geological model and used to develop the hydraulic conductivity zones of the cross-sectional groundwater flow model:

1) af – Artificial fill (Holocene, Anthropocene): The modeled layer was developed from interpreted fill contact points from the SIB Project Area PDI, historical ground investigations and, pre-fill surface from digitized 1931 contour map.

2) afb – Recent Basin Sediments: Recent sediment contacts were developed from in-water Cone Penetration Testing (CPT) data, borehole data from the SIB Project Area PDI and historical bathymetric surfaces. The historical bathymetric dataset was the combination of 20 bathymetry surveys from 1938 through 2022 with lowest elevation presented on the surface over this data range.

3) Qa – Alluvium (Holocene) Sand: The surface was developed from interpreted Alluvium (Holocene) sand contacts with other encountered strata from the SIB Project Area PDI.

4) Qa – Alluvium (Holocene) Clay: The surface was developed from interpreted contact between Alluvium (Holocene) Clay contacts and the underling Qf Missoula flood deposits. Data was interpreted from the SIB Project Area PDI and historical ground investigations.

5) Qf Missoula flood deposits – Silt & Sand: The surface was developed from interpreted layers of silt and sand from primarily onshore and in-water CPT data collected during the the SIB Project Area PDI.

6) Qfc – Coarse-grained Missoula flood deposits & Tt - Troutdale Formation (Pliocene and Miocene): Surfaces were developed from historical ground investigation, PB-1003R and geological mapping cross sections. The layers were projected to underlie the entire modeled area and fall below the base of the cross-sectional model.

Hydraulic conductivity was applied to the hypothetical cross-sectional model based on the most common (mode) hydrostratigraphic unit across the 2,000-ft-wide modeled area based on the SIB Project Area geological model. Only the first five hydrostratigraphic units were incorporated into the cross-sectional model because the sixth (coarse-grained Missoula flood deposits and troutdale

formation) were below the bottommost layer in the model. Hydraulic conductivity zones outside of the SIB Project Area geological model area were extrapolated from those areas that overlapped the SIB Project Area geological model (Figure 2-5). This generally involved extrapolating along straight lines, with the exception of recent basin sediments that were added beneath the Willamette River to be consistent with those observed beneath SIB.

3.0 MODEL FITTING AND SENSITIVITY

The hypothetical cross-sectional model was fit to 50-hour tidally averaged specific discharges in SIB from July 2023. Modeling fitting was performed using Parameter Estimation software (PEST), specifically PEST++ (White et al., 2020) using the built-in interface in Groundwater Vistas.

Horizontal hydraulic conductivity was fit for each zone within the range of observed values for similar stratigraphic units and lithologies. Vertical to horizontal hydraulic conductivity anisotropy for each zone was fit within a range of 1:20 to 1:1. Table 3-1 presents the initial horizontal hydraulic conductivity and vertical hydraulic conductivity anisotropy used for each zone as well as the lower and upper bounds for PEST++ and the final fit values that were applied to the hypothetical cross-sectional model.

The model was reasonably fit to observed specific discharge to SIB that were averaged in the same manner as the riverbed vertical hydraulic conductivities (Figure 3-1). The specific discharge for the third reach from the northeast bank was adjusted up from 0.028 cm/d to 0.076 cm/d to better align with adjacent reaches and to account for the higher observed specific discharge at 6D that was located in the second reach, just outside of the third reach. Cross sectional specific discharge targets and modeled specific discharges for each reach are presented in Table 3-2 with the comparison to modeled values. Both specific discharges (cm/d) and groundwater fluxes in cubic ft per day (ft^3/d) are presented. Groundwater fluxes represent the volume of water discharging from each reach that is modeled over an area 5-ft by 80-ft (longitudinally) in the hypothetical cross-sectional model. By convention, modeled groundwater flux values are negative if water is discharging from groundwater to surface water and positive if surface water is discharging to groundwater, this is reversed from the observed specific discharge values presented in the Porewater Upwelling Report where specific discharge from groundwater to surface water was positive (Appendix B of PDI ER; HGL, 2024a). Figure 3-2 visually compares the observed and modeled specific discharges.

Following model fitting, a sensitivity analysis was performed to assess how adjusting horizontal hydraulic conductivity and vertical hydraulic conductivity affected the model fit. A sensitivity analysis was performed for all parameters that were fit using PEST++. Parameters were adjusted both up and down by set multipliers for each zone individually while all other parameters and zones were held constant at their fit values. The sensitivity of a parameter is assessed by how changes to that parameter influence the goodness of fit of the model. In this case, sensitivity is assessed by how parameters affect the sum of square residuals for groundwater discharge to SIB in reaches 1 through 7.

The sensitivity analysis for horizontal hydraulic conductivity zones is presented in Figure 3-3. The Missoula flood deposits zone was the most sensitive to changes; with increases in the horizontal hydraulic conductivity negatively impacting the resulting fit (the sum of square residuals increased

substantially). Most groundwater flow within the hypothetical cross-sectional model occurs within the Missoula flood deposits zone and increasing the horizontal hydraulic conductivity results in more flow from the upland constant head boundary that discharges to SIB and the Willamette River. Similarly, reducing the horizontal hydraulic conductivity of the Missoula flood deposits results in less flow from the upland constant head boundary and less discharge to SIB and the Willamette River.

The sensitivity analysis for vertical hydraulic conductivity zones is presented in Figure 3-4. The recent basin sediments and alluvium clay zones were the most sensitive zones to changes. These two zones directly underlay SIB and groundwater needs to flow vertically upward to discharge to surface water. Therefore, the vertical hydraulic conductivity of these two zones influences the specific discharge. However, the maximum sum of square residuals (approximately 4) is about 35 times lower than the maximum sum of square residuals for the Missoula flood deposits horizontal hydraulic conductivity (approximately 140).

4.0 MODEL RESULTS AND UNCERTAINTY

Three Willamette River stage scenarios were simulated to estimate the groundwater elevation along the banks of SIB. The modeled scenarios were the July 2023 observed specific discharge stage (8.09 ft NAVD88), ordinary high water (20.075 ft NAVD88), and moderate flood stage (29 ft NAVD88) based on classifications from the National Water Prediction Service at Morrison Bridge (NWPS, 2025b).

Models were updated to replace the upland constant head boundary with a constant flux boundary with the same groundwater flux entering the upland boundary as the fit model. The boundary reach report that reports the groundwater flux entering and leaving the model for the fit, July 2023 model is presented in Table 4-1. Reaches 923 through 973 indicate the groundwater flux at each constant head boundary cell with the last two digits (e.g., 23) indicating the model layer where the boundary node is located. Converting to constant flux boundaries allows the groundwater level at the upland boundary to fluctuate with the river stage, but this limits the groundwater flux entering and leaving the model to what was observed in July 2023 (i.e., the model scenarios do not simulate lower or higher groundwater discharge scenarios). As indicated in Section 1.6, July was chosen due to its proximity to maximum annual upwelling to SIB (Appendix B of PDI ER; HGL, 2024a); therefore, the simulated groundwater discharge elevations are considered conservative.

Groundwater elevations were monitored at two points within the cross-sectional model: at an SIB bank elevation of 10 ft NAVD88 screened between 0 and -2 ft NAVD88 and at an SIB bank elevation of 20 ft NAVD88 screened between 0 and -2 ft NAVD88. These locations were selected to provide comparisons between scenarios and to allow for uncertainty to be automatically monitored; however, the extent of groundwater discharge zone varies based on the river stage and the upland boundary.

The groundwater elevations at the two monitoring points and at the water table adjacent to the highest river boundary cell that was saturated are presented in Table 4-2. Groundwater discharges to SIB approximately 0.5 to 0.6 ft above the simulated Willamette River stage from the northeast with groundwater levels about 1 ft above the river stage in the two monitoring wells. The cross-sectional results of the measured SIB discharge model from July 2023 are presented in Figure 4-1,

the result of the ordinary high water scenario is presented in Figure 4-2, and the result of the moderate flooding scenario is presented in Figure 4-3. In each scenario, the groundwater level across Swan Island was approximately at the elevation of the Willamette River stage, indicating that groundwater discharge to surface water is fairly limited along the banks and likely occurs as exchange caused by tidal fluctuations (i.e., groundwater discharge to surface water during low tide and surface water discharge to groundwater during high tide).

The uncertainty of the groundwater discharge to SIB elevation was evaluated similar to the sensitivity analysis (by varying the horizontal hydraulic conductivity, vertical hydraulic conductivity, and constant head boundary for the July 2023 observed specific discharge scenario) and evaluating the resulting change in groundwater levels above the SIB stage. The groundwater level above the SIB stage was monitored at the 20-ft bank elevation monitoring point from 0 to -2 ft NAVD88. The parameters that were fit using PEST++ were included in the uncertainty analysis as was the upgradient constant head to assess how each model parameter that was either fit or assumed influences the groundwater discharge elevation above the SIB stage.

The groundwater level above the SIB stage at the 20-ft bank elevation monitoring point ranged from 1.4 to 3.2 ft above the SIB stage when horizontal hydraulic conductivities were adjusted from $1/10^{th}$ the fit value to 10-times the fit value. Like the sensitivity analysis, adjusting the horizontal hydraulic conductivity of the Missoula flood deposit zone resulted in the largest variation in groundwater levels above the SIB stage (Figure 4-4). Increases to the horizontal hydraulic conductivity of the Missoula flood deposit zone allows more flow through those deposits extending to the model boundaries which caused groundwater levels to increase near SIB (i.e., the resistance to groundwater flow in the Missoula flood deposit zone was lower, so higher heads propagated further into the model). An opposite interaction resulted from increasing the horizontal hydraulic conductivities in the alluvium clay, alluvium sand, and recent basin sediments zones because they are immediately adjacent to SIB and the Willamette River (Figure 4-4). Increasing the hydraulic conductivity in zones adjacent to the river boundaries enables groundwater to more easily discharge to river boundaries and thus lowers the groundwater level adjacent to SIB, especially in the alluvium clay where the 20-ft bank elevation monitoring point was located. Finally, adjusting the horizontal hydraulic conductivity of the artificial fill does little to change the groundwater level in the 20-ft bank elevation monitoring point because the artificial fill has limited saturation upgradient of SIB under the July 2023 observed specific discharge scenario (Figure 4-1).

The groundwater level above the SIB stage at the 20-ft bank elevation monitoring point ranged from 1.2 to 2.3 ft above the SIB stage when the vertical hydraulic conductivities were adjusted from $1/10^{th}$ the fit value to 10-times the fit value. Like the sensitivity analysis, adjusting the vertical hydraulic conductivity of the alluvium clay and recent basin sediments resulted in the largest variation in groundwater levels above the SIB stage (Figure 4-5). Increases to the vertical hydraulic conductivity resulted in lower groundwater levels adjacent to SIB because groundwater was able to move vertically and discharge to SIB more easily. Conversely, decreasing the vertical hydraulic conductivity of the alluvium clay and recent basin sediments resulted in groundwater flow being reduced to SIB and heads increasing adjacent to SIB as a result. Changes to the vertical hydraulic conductivity for the artificial fill, alluvium sand, and Missoula flood deposits had relatively little effect on groundwater levels adjacent to SIB (Figure 4-5).

The groundwater level above the SIB stage at the 20-ft bank elevation monitoring point ranged from 0.7 to 3.0 ft above the SIB stage when the constant head boundary elevation was adjusted between 10 ft NAVD88 to 30 ft NAVD88 (Figure 4-6). The groundwater level adjacent to SIB varied approximately linearly over the range of constant heads simulated. The constant head value of 18 ft NAVD88 was selected for model fitting based on observed groundwater levels in wells from the Portsmouth Force Main Geotechnical Data Report (Brown and Caldwell, 2008) and the Daimler Truck Groundwater Source Control Investigation Report (GSI and SSPA, 2020).

5.0 DISCUSSION AND RECOMMENDATIONS

A hypothetical cross-sectional model was developed for the SIB Project Area and upland area that averaged model properties across a 2,000-foot-wide area near the center of SIB (Figure 2-1). The model was fit to observed specific discharges to SIB from July 2023 and a sensitivity analysis was performed for the fit horizontal and vertical hydraulic conductivity zones. Model results at monitoring points along the banks of SIB at a 10-ft elevation and 20-ft elevation were evaluated for multiple Willamette River stage scenarios and an uncertainty analysis was performed to investigate how groundwater levels adjacent to SIB may change with different model parameters. The range of groundwater levels relative to the SIB ranged between approximately 0.5 and 2 ft above the SIB stage based on the scenarios evaluated and the uncertainty analysis performed.

5.1. ASSUMPTIONS AND LIMITATIONS

The hypothetical cross-sectional model required a number of assumptions and simplifications of the groundwater flow system in the SIB Project Area. The specific assumptions and limitations are listed below.

- The cross-sectional model simplified the topography, bathymetry, lithology, and boundary conditions from a heterogeneous area with likely complex groundwater flow and discharges to an averaged two-dimensional model that limits groundwater flow to only flowing perpendicular to SIB and the Willamette River. Actual groundwater flow is likely not perfectly perpendicular to SIB and most likely has a somewhat semi-circular shape corresponding to Willamette Bluff. As a result, the elevation that groundwater discharges to SIB is likely not constant across the entire bank. Similarly, groundwater was not modeled as flowing into Swan Island from the southeast where it connects to Mocks Bottom. This may occur to a limited degree and would result in the model underestimating groundwater elevations beneath Swan Island.
- Limited groundwater level observations were available for model fitting and determining the upland constant head boundary and no groundwater level observations were available in July 2023 when specific discharge at SIB was measured. As a result, the constant head boundaries were based on available Mocks Bottom groundwater observations from 2006 to 2008 and 2019 that were located near Willamette Bluff. The limited groundwater level observations are a data gap for the modeling.
- The use of an upgradient constant head boundary based on limited observed groundwater elevations for model fitting resulted in the fit horizontal hydraulic conductivity and vertical to horizontal hydraulic conductivity anisotropy being tied to the selected constant head

boundary. If an alternative constant head boundary was selected, the resulting model fitting would have yielded different fit hydraulic conductivities.

- The upland boundary was converted from a constant head boundary to a constant flux boundary for the ordinary high water and moderate flooding scenarios. Because the upland groundwater flux into the model was maintained between the three scenarios, the modeled groundwater discharge to SIB and the Willamette River was identical. This results in fairly similar groundwater elevations relative to the SIB and Willamette River stage, with minor differences attributed to additional groundwater moving through the artificial fill with a higher river stage. The model was not fit to higher or lower groundwater specific discharges and so the modeled scenarios do not provide insight into the elevation of groundwater discharging to SIB with either higher upland groundwater flux or lower upland groundwater flux. The observed groundwater flux in July 2023 was selected to sample the expected maximum specific discharge to SIB (Appendix B of PDI ER; HGL, 2024a). By using the likely annual maximum groundwater specific discharge to SIB, the model is more conservative (i.e., will calculate a higher groundwater discharge elevation above the SIB stage) than if a lower specific discharge had been used for model fitting and for developing the constant flux upland boundary conditions.
- Limited lithologic borings were available in the upland area of the cross-sectional model and this area was not included in the LeapFrog geological model interpolation performed for the SIB Project Area. The modeled hydraulic conductivity zones in the upland area were extrapolated from the available stratigraphic interpretations and boring logs.
- A limited number of hydraulic conductivity measurements were available for site hydrostratigraphic units, including no measured hydraulic conductivities for the artificial fill. This represents a data gap for constraining the fit parameters.
- Uniform horizontal hydraulic conductivity and vertical to horizontal hydraulic conductivity values were applied for each of the five modeled zones (artificial fill, recent basin sediments, alluvium clay, alluvium sand, and Missoula flood deposits). Each of these zones are likely heterogeneous with lenses of fine and coarse material that is not distributed evenly across the modeled area. Heterogeneities may contribute to preferential flow paths that result in groundwater discharging at varying rates along the SIB bank and at varying elevations. The presence of subsurface heterogeneity is a data gap and would be informative if a 3D numerical model were developed in the future.
- The model was fit to and simulates steady-state average tidal conditions. Transient influence from higher and lower river stage resulting from either tidal influence or from increased precipitation over the Willamette River drainage area were not simulated. The higher river stages simulated (ordinary high water and moderate flooding) are likely temporary and upland groundwater levels likely take time to rise in response meaning that discharge at higher river stages is likely lower than at more average river stages and consequently the groundwater discharge elevation is likely closer to the SIB water surface during higher river stages. Because the model was steady state, storage parameters were not adjusted and remained constantT.

5.2. RECOMMENDATIONS

Groundwater modeling using the fit hypothetical cross-sectional model indicates that groundwater-surface water exchange on the Mocks Bottom side of the SIB Project Area occurs within an area up to 2 ft above the SIB stage. Groundwater-surface water exchange on the Swan Island side of SIB occurs over a more limited area that is approximately equal to the SIB stage to approximately 0.5 ft above the SIB stage, which results in very little groundwater discharge at elevations above ordinary high water (approximately +20 ft NAVD88) The chemical isolation layer is designed to intercept groundwater-surface water exchange by extending its coverage above the ordinary high water elevation by 2 feet (+22 ft NAVD88) on the Mocks Bottom (northeast) side of SIB and 0.5 feet (+20.5 ft NAVD88) on the Swan Island (southwest) side of SIB.

TABLES

Table 1-1
Hydraulic Conductivity Measurements by Stratigraphic Unit and Lithology
Groundwater Discharge Modeling Technical Memorandum, Swan Island Basin Project Area, Portland, Oregon

Stratigraphic Unit	Lithology	Hydraulic Conductivity (ft/d)	Source
Qal - Alluvium (Quaternary)	Interbedded silt, sandy silt, and silt with sand	8.50E-03	Brown and Caldwell, 2008
Qal - Alluvium (Quaternary)	Poorly graded sand with silt	1.53E-01 to 5.95E-01	Brown and Caldwell, 2008
Qal - Alluvium (Quaternary)	Silt/Clay	5.10E-03 to 1.98E+00	EPA, 2016
Qal - Alluvium (Quaternary)	Silty sand	9.92E-02 to 1.98E+00	EPA, 2016
Qal - Alluvium (Quaternary)	Sand	5.10E-03 to 3.12E+01	EPA, 2016
Qfc - Coarse-grained facies (Pleistocene)	Sand and gravel	3.12E+00 to 3.97E+01	EPA, 2016
Qff - Fine-grained facies (Pleistocene)	Poorly graded sand	1.02E-02 to 1.33E-02	Brown and Caldwell, 2008
Qff - Fine-grained facies (Pleistocene)	poorly graded gravel with sand less than 5 feet thick	5.95E-01	Brown and Caldwell, 2008
Tt - Troutdale Formation (Miocene to Pliocene)	Very dense, poorly graded gravel (cemented and uncemented)	1.67E+03	Brown and Caldwell, 2008
Tt - Troutdale Formation (Miocene to Pliocene)	Poorly graded sand with silt lenses less than 12 feet thick	2.83E+00 to 4.54E+00	Brown and Caldwell, 2008
Tt - Troutdale Formation (Miocene to Pliocene)	Silty sand lenses less than 12 feet thick	9.92E-02	Brown and Caldwell, 2008

Notes:

ft/d = feet per day

FLOOD IMPACT EVALUATION TECHNICAL MEMORANDUM

FLOOD IMPACT EVALUATION TECHNICAL MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
SWAN ISLAND BASIN PROJECT AREA, CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

This Flood Impact Evaluation Technical Memorandum presents a summary of no-rise analysis efforts for the Pre-Final 90% Remedial Design (RD). The Pre-Final 90% RD was conducted for the Swan Island Basin (SIB) Project Area within the Portland Harbor Superfund Site (PHSS) in Portland, Multnomah County, Oregon. The HydroGeoLogic, Inc. (HGL) team performed the work on behalf of the SIB RD Group based on the requirements of the PHSS Record of Decision (ROD) (EPA, 2017) and the Administrative Settlement Agreement and Order on Consent (EPA, 2021a).

The objective of this memorandum is to summarize the no-rise analysis for SIB Project Area, which assessed whether proposed Remedial Actions (RA) would increase the 100-year flood water surface elevation (WSE). The SIB Existing Conditions Model and Proposed Conditions Model were developed using the original Hydrologic Engineering Center River Analysis System (HEC-RAS; USACE, 2020) setup to represent conditions in the SIB Project Area. The Corrected Effective Model for the PHSS, developed by CDM Smith (2024a; 2024b), served as the basis for both models. This memorandum outlines the modeling methodology, analysis approach, and relevant data.

Section 1 presents an overview of the PHSS Corrected Effective Model (CDM Smith, 2024a). Section 2 describes the development of the SIB Existing Conditions Model for the SIB Project Area and demonstrates consistency with flood predictions from the Corrected Effective Model. Section 3 describes the development of SIB Proposed Conditions Model (post-RA conditions) and presents the results of the no-rise analysis. Section 4 provides analysis conclusions.

1.0 PORTLAND HARBOR SUPERFUND SITE CORRECTED EFFECTIVE MODEL

CDM Smith (2024a, 2024b) developed the Corrected Effective Model to represent current conditions on the Willamette River in Portland, Oregon, as part of the no-rise analysis for proposed remedial actions at the PHSS. Per CDM Smith (2024a), the model satisfies the substantive requirements of Executive Orders related to Floodplain Management, as well as the City of Portland's floodplain management regulations under its participation in the National Flood Insurance Program. CDM Smith (2024a) recommended that project stakeholders use this model as the foundation for developing existing and proposed conditions models to demonstrate compliance with no-rise criteria for their remedial actions.

The Corrected Effective Model, based on the HEC-RAS framework, provided flood water level results for River Stations (RS) 0.25 to 25.895, as documented in CDM Smith (2024a). Additional background on model development including Manning's n values, ineffective flow areas and channel geometry is available in CDM Smith (2024a, 2022). This model served as the foundation

Corporate Headquarters
11107 Sunset Hills Road, Suite 400
Reston, Virginia 20190

for both the SIB Existing Conditions Model and Proposed Conditions Models discussed in Sections 2.0 and 3.0.

2.0 SIB EXISTING CONDITIONS MODEL

2.1. MODEL DEVELOPMENT

The SIB Existing Conditions Model was developed by incorporating six additional cross sections into the Corrected Effective Model to better represent the site-specific geometry in the SIB Project Area, and to reflect anticipated bathymetric changes from remedial activities—specifically dredging and capping—in SIB. These cross sections, added between river miles (RM) 7.826 and 9.095 (shown as red lines in Figure 2-1), were introduced solely to enhance geometric representation; the underlying terrain in the SIB Existing Conditions Model remains unchanged from the Corrected Effective Model. This approach ensures accurate representation of current site conditions while maintaining a consistent framework for evaluating proposed conditions.

The new cross-sections maintain continuity with adjacent sections from the Corrected Effective Model by using consistent parameters such as Manning's n values, contraction and expansion coefficients, and ineffective flow areas defined in the Corrected Effective Model. Specifically, both models use contraction and expansion coefficients of 0.1 and 0.3, respectively, across the entire model domain. For the cross sections added in the Existing Conditions Model, Manning's n roughness coefficients range from 0.08 to 0.12 in the overbank areas and 0.03 in the main channel, consistent with adjacent cross-sections from the Corrected Effective Model

The hydrology used in the SIB Existing Conditions Model including 100-year recurrence interval flow data for the Willamette River below the Clackamas River (375,000 cubic feet per second [cfs]) and below the Multnomah Channel (263,000 cfs) is identical to that applied in the Corrected Effective Model. As in the Corrected Effective Model, the downstream boundary condition at the confluence of the Willamette and Columbia Rivers was defined using water surface elevations from the Federal Emergency Management Agency Flood Insurance Study (2004/2010): 30.8 feet (ft) North American Vertical Datum of 1988 (NAVD88) 100-year flood event. Additional information on hydrology, boundary conditions, and terrain data is available in CDM Smith (2024a).

2.2. ANALYSIS AND RESULTS

The SIB Existing Conditions Model was used to simulate the 100-year flood WSEs. Figure 2-2 shows example WSE distributions near the SIB Project Area for the Corrected Effective Model (left) and the SIB Existing Conditions Model (right). Modeled WSE results along the river centerline (shown as the blue line in Figure 2-1) were extracted for analysis. Figure 2-2 compares WSE profiles from the SIB Existing Conditions Model and the Corrected Effective Model, showing elevation differences less than 0.035 ft. These differences are only a result of additional cross sections added to the SIB Existing Conditions Model.

Table 2-1 summarizes modeled WSEs and WSE differences for the Corrected Effective Model and the SIB Existing Conditions Model. WSE differences were observed near the SIB (although negligible), between RM 7.826 and RM 9.095, where new cross sections were added in the SIB Existing Conditions Model.

3.0 SIB PROPOSED CONDITIONS MODEL

3.1. MODEL DEVELOPMENT

The Proposed Conditions Model was next developed to perform the no-rise analysis, a regulatory requirement that ensures floodplain modifications, such as RA involving dredging and capping, do not result in a measurable increase in the 100-year flood WSEs. The Proposed Conditions Model represents the future site conditions including proposed RA within the SIB Project Area between RM 7.826 and 9.095, representative of the Pre-Final 90% RD. Figure 3-1 compares terrain surfaces in the SIB Existing Conditions Model (left) and Proposed Conditions Model (right). The Proposed Conditions Model terrain surface was developed by incorporating the final elevations in the Pre-Final 90% RD. Terrain modifications were only prescribed in the SIB Project Area, and all cross-section related input parameters such as Manning's n values, contraction and expansion coefficients, and ineffective flow area treatments were kept consistent with the SIB Existing Conditions Model.

3.2. NO-RISE ANALYSIS RESULTS

The 100-year flood event was simulated using the Proposed Conditions Model, applying the same hydrology (see Sectio 2.1) and downstream boundary conditions as in the Existing Conditions Model. Results were analyzed to assess changes in WSE for the no-rise analysis. Figure 3-2 illustrates the example WSE distribution near the SIB Project Area for the SIB Existing Conditions Model (left) and Proposed Conditions Model (right). Figure 3-3 compares WSE profiles along the river centerline from the Existing Conditions Model and the Proposed Conditions Model. Table 2-1 summarizes modeled WSEs for the Proposed Conditions Model, along with differences relative to the SIB Existing Conditions Model. Results show that changes in WSE caused by the proposed RA in SIB are below 0.01 ft. These results confirm that the RA for the SIB Project Area, as designed, does not cause a measurable increase in WSEs in the river. These changes are logical given that the RA for the SIB Project Area is largely located within a backwater area, and no significant capping above existing grade is proposed in the outermost area of SIB.

4.0 CONCLUSIONS

The current modeling effort successfully incorporated additional cross sections into the SIB Existing Conditions Model and confirmed consistency with the PHSS Corrected Effective Model. The geometric enhancements improved representation of SIB Project Area flow conditions. Results confirmed consistency with the Corrected Effective Model, showing minimal differences in simulated 100-year flood WSEs.

The Proposed Conditions Model, representing future conditions with RA, demonstrated no measurable increase in 100-year flood WSE compared to existing conditions. The project was demonstrated to meet the no-rise criteria.

ATTACHMENT C

RIVERBANK CHEMICAL ISOLATION LAYER MODELING TECHNICAL MEMORANDUM

RIVERBANK CHEMICAL ISOLATION LAYER DESIGN TECHNICAL MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
SWAN ISLAND BASIN PROJECT AREA, CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

This Riverbank Chemical Isolation Layer (CIL) Design Technical Memorandum presents a summary of the design basis of the CIL for vegetated areas of Swan Island Basin (SIB) Project Area riverbanks above the mean high water (MHW) elevation.

Section 1 presents an overview of the considerations made for the design of the CIL for vegetated areas on riverbanks. Section 2 presents the modeling approach and parameters used to evaluate the protectiveness of the CIL, as well as the modeling results. Section 3 describes the construction requirements for the vegetated CIL on riverbanks. Section 4 provides a list of references used in the generation of this technical memorandum.

1.0 CIL CONSIDERATIONS FOR VEGETATED RIVERBANK AREAS

Surface soils on the riverbank portion of the Project Area are generally dry. A chemical isolation layer design for the riverbanks will experience significantly less net seepage than the submerged areas of the river. The riverbank CIL design requirements are therefore different than the subaqueous cap that is designed for regions of SIB that are below the MHW elevation (+13 ft NAVD88).

For riverbank areas that are steep grades (steeper than 3H:1V) and around structures, rock revetment is used as the surface treatment. For these areas, a reactive core mat (RCM) CIL will be placed beneath the stone. The RCM CIL was evaluated for conservative modeled conditions for seepage rates on riverbanks where vegetation will not be drawing down soil moisture through evapotranspiration. The evaluation of the RCM CIL is provided in the Cap Design Technical Memorandum (CDTM) (Volume I, Appendix E).

The SIB Project Area Pre-Final 90% Remedial Design incorporates ecological features. As a result, the riverbanks will be planted and protected against erosion with native vegetation communities where such treatment is precluded by shoreline structures, steep slopes that require engineering stabilization, or requirements of the property owner or facility operation. The vegetated areas require a subsurface that is amenable to vegetation root growth and health, and so the CIL in these areas was designed to encourage plant growth.

The medium of topsoil is an organic-rich, natural material that meets this requirement. The vegetated CIL is designed to be a topsoil amended with a biochar, a high-carbon product with significant reactive surface area that is produced from the pyrolysis of agricultural waste products. The biochar is reactive in a similar way to the activated carbon used in the subaqueous capping system in that the amendment. Additionally, biochar is often used in agricultural settings to

improve soil fertility as well as being a renewable resource. Biochar has the added benefit of having a much smaller environmental footprint than activated carbon because it is manufactured at lower temperatures, making it an excellent green remediation product.

2.0 MODELING APPROACH AND PARAMETERS

This section describes the groundwater modeling basis for the CIL design in Section 2.1. The 1-dimensional advective transport modeling for the CIL effectiveness was measured in CapSIM, as described in Section 2.2

2.1. GROUNDWATER MODELING INFORMATION FOR CIL DESIGN

Attachment A (Groundwater Modeling Technical Memorandum) of the Riverbank Design Technical Memorandum (RDTM) presents an overview of the SIB Project Area conceptual site model, specifically related to surface water and groundwater hydrology. Attachment A also provides details of the numerical groundwater model created and used in the riverbank design.

The numerical groundwater model was calibrated to the ordinary low water conditions. However, to understand the magnitude of the daily groundwater flux from the riverbank at different intervals, this groundwater model was set to reflect ordinary high water (OHW) conditions (approximately 20.1 ft NAVD88). Figure C–1 shows the relative contributions to a flux at discreet intervals along the cross-section averaged riverbank at the inundated elevations. These fluxes are anticipated to be very short-lived as the water level drops and the water table subsequently drops. On the Mocks Bottom side of SIB, the water table is driven by a combination of the upgradient areas (from the north-northeast) and the river surface. However, the Swan Island side of SIB does not have the same “upgradient” potentiometric effect; this peninsula has river water on both sides of it, and the river surface fluctuation alone drives the groundwater elevations and behavior on this side of SIB. Figure C-1 shows the findings of the modeling for the OHW condition, which indicates that groundwater tends to discharge at slightly higher rates at near the water surface elevation for these ephemeral conditions. Figure C-2 shows a plot of the model-produced seepage flux values from the riverbanks at river stage 8 ft NAVD88 and OHW (20 ft NAVD88) conditions, and this plot visually shows that seepage rates are at their maximum near the water surface elevations; the 8 ft NAVD88 stage has a noticeably higher peak Darcy flux lower on the slope (the ordinate axis shows the groundwater model “reach” identifier, but the reaches are displayed in the same orientation as the cross section in Figure C-1) where the water meets the bank. A similar effect is shown for the river elevation at the 8 ft NAVD88 condition. Though the 8 ft NAVD88 condition is below the riverbank areas, it is useful to understand a more complete picture of the modeled groundwater seepage behavior at this river stage.

The elevated seepage rates at the river surface were used to conservatively determine an annual equivalent Darcy flux at different riverbank elevations, as shown in Table C-1. The percent of the year that the river surface submerges the different riverbank elevations is determined from the data presented[1] in the RDTM Figure 4-1. Because the modeled seepage rates diminish (as shown in Figure C-2) when the river surface exceeds these elevations, a Darcy flux value of 0.4 centimeter (cm)/day is a conservative, single-value estimate for the time-varying Darcy flux.

[1] The values are derived for the percent of time submerged “All” (dashed line), rather than the “Growing Season” line.

Table C-1 Equivalent Annual Darcy Flux at Different Riverbank Elevations from Groundwater Model

Elevation (ft NAVD88)	Percentage of year river surface exceeds elevation	Equivalent Days	Total Dary flux (cm/yr) at 0.4 cm/day discharge rate	Notes
13	17.5-18	64	25.6	Lowest riverbank elevation/MHW
14.5	11	40	16	Emergent Wetland Boundary
15.5	8	29.2	11	Interim elevation
17	5	18.3	7.4	Interim elevation
20	1.2	4.4	1.8	OHW

The highest annual total Darcy seepage (in units of cubic cm [cm^3] per year per square cm [cm^2] of riverbank in the vertical plane, simplifying to cm/year) occurs at the lowest elevation of the riverbank. This maximum discharge was used as the "seepage velocity" to evaluate the performance of the chemical isolation layer, as described in Section 2.2. As shown in these results, a significant decrease (57 percent) in the total seepage occurs at an elevation 2.5 ft above the MHW elevation (15.5 ft NAVD88), so a significant portion of the riverbanks experiences much less Darcy flux throughout the year than the lowest elevations of the Project Area riverbank.

Attachment A provides additional discussion of the groundwater model created for riverbank design considerations. There are limitations to this model because the measurement information (piezometers and monitoring wells elevations) is limited within SIB. However, the physical model, based on best practices (in the absence of complete monitoring conditions), is helpful to produce scenarios that are useful for design purposes.

2.2. CIL MODELING IN CAPSIM

The maximum annual discharge value (rounded up to 26 cm per year) was selected to model the effectiveness of riverbank topsoil and biochar mixtures as a CIL. This evaluation of the migration of contaminants of concern within groundwater, through the CIL was performed in CapSIM. The CapSIM platform is described in more detail within the Section 2.1 and 2.2 of the CDTM (Volume I, Appendix E). Similarly to the cap design modeling, the sitewide SIB 95th percentile values of COCs were assigned within riverbank soils, which is a more conservative (higher) value for all COCs than the investigation sample set from only riverbank samples.

The CIL is designed as a mixture of topsoil and 3 percent by weight biochar (assumed to contain 70 percent organic carbon). Within CapSIM, the sorption parameters of the underlying riverbank soil were the same as detailed in the CDTM Attachment C – Sorption Parameter Memorandum. This material uses Project Area-adjacent linear partitioning coefficients within this bottom layer of the model. The sorption relationship used for all organic constituents is the organic-carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} of the topsoil and biochar mixture. Due to the porous nature of biochar and the reactive nature of the carbon within the material, the use of the sorption coefficients used in CapSIM are anticipated to be conservative in the estimates of sorption for this component of the CIL. The organic carbon content of the imported

topsoil component of the CIL mixture was assumed to be the minimum required by the specifications of 2 percent.

These results of the CapSIM modeling for inorganic and organic COCs are presented in Table C–2. This table reports the modeled porewater concentrations at 100 years of cap performance (assuming no degradation of COCs). Even for the conservative conditions modeled, the riverbank CIL performs well in protecting the bottom of the topsoil layer (24 inches below the vegetated surface).

2.3. NATURAL PHENOMENA UNACCOUNTED FOR WITHIN THE CHEMICAL MODEL

The CapSIM model created for the RD does not account for biodegradation or phytoremediation of the COCs, evapotranspiration that significantly reduces the actual seepage from the riverbank. These aspects of the physical and biological phenomena setting of the riverbank environment serve to reduce the actual water, seepage and flux of COCs. The most significant is the rooting zone in the woody vegetation above 14.5 ft will evapotranspire soil moisture such that much of the riverbank soil will be dry, especially during the growing season. This will diminish the total annual COC flux and so actual contaminant migration will occur at a fraction of the rate modeled.

Another feature of the riverbank environment is the intermittent nature of the surface water elevations above high water. The varying surface and groundwater elevations will result in a significant mass of oxygen pushed and pulled into the pore space of the riverbank soils, creating variably aerobic and anoxic conditions within the soils. This gas exchange serves to maintain a highly biologically active soil, and these conditions create biologically-mediated degradation of degradable COCs. It is very difficult to produce quantitative estimates of the reduction of contaminants, but these phenomena in total provide a highly protective soil cover system for the remediation of SIB Project Area riverbanks.

3.0 CONSTRUCTION REQUIREMENTS FOR VEGETATED AREAS

Both the imported topsoil and the biochar amendments will be tested to verify the materials contain no COCs above CUL concentrations before importing the material to the Project Area.

The selected RA contractor will produce and place this CIL mixture in a cellular containment system (geocells) to provide assurance of the full thickness for the CIL. The cellular contain system also provides a quality control function during the construction in requiring placement in layers and compaction to the density required from the design, as well as providing resistance to erosion during construction. The topsoil placed on top and the establishment of vegetation on top of the CIL will provide a permanent protection to the CIL.

CAP DESIGN TECHNICAL MEMORANDUM

This page was intentionally left blank.

CAP DESIGN TECHNICAL MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
SWAN ISLAND BASIN PROJECT AREA, CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

This Cap Design Technical Memorandum (CDTM) presents a summary of cap design efforts and recommendations for the Pre-Final 90% Remedial Design (RD). The 90% RD is conducted for the Swan Island Basin (SIB) Project Area within the Portland Harbor Superfund Site (PHSS) in Portland, Multnomah County, Oregon. The HydroGeoLogic, Inc. (HGL) team performed the work on behalf of the SIB RD Group based on the requirements of the PHSS Record of Decision (ROD) (EPA, 2017) and the Administrative Settlement Agreement and Order on Consent at the SIB Project Area (EPA, 2021a). The data used in this cap evaluation were collected in accordance with the final Pre-Design Investigation (PDI) Work Plan, which the U.S. Environmental Protection Agency (EPA) and were reported in the PDI Evaluation Report (ER), which the EPA approved in January 2025 (HGL, 2024a).

The Cap Evaluation Technical Memorandum was included in the Basis of Design Report (BODR) (HGL, 2024b) and was subsequently updated and appended as Appendix A– Cap Evaluation to the Remedial Design Work Plan (RDWP) (HGL, 2025a), which was conditionally approved on February 28, 2025. The Draft 50% RD CDTM used the same guidance documents and criteria, as well as design performance standards available, to develop recommendations for cap design. This 90% RD CDTM presents area-specific cap design for the SIB Project Area. It resolves limitations of the Draft 50% RD Design, builds upon recommendations in the Draft 50% RD (e.g., geotechnical analysis consolidation parameters), and incorporates the latest 2025 Cap Design Criteria at Portland Harbor (EPA, 2025a), Portland Harbor Superfund Site Monitoring Guidelines (EPA, 2025b), EPA's Guidelines for Reporting Porewater Studies Using Polymeric Passive Samplers (EPA, 2025c), and EPA's DRAFT Guidelines for Riverbank Characterizations and Evaluations at the Portland Harbor Superfund Site (EPA, 2025d).

This CDTM describes the cap design based on individual layers. Section 1 describes area-specific analysis of the underlying sediment driving cap design. Section 2 describes cap evaluation efforts for quantifying maximum contained sediment concentration and breakthrough for each chemical isolation layer (CIL) alternative. Section 3 discusses physical considerations used in this cap evaluation as well as the selection of erosion protection and unamended habitat mix layers. Section 4 discusses area-specific cap alternative assignments. Structural and geotechnical considerations for cap placement are detailed in the Geotechnical Design Technical Memorandum (GDTM, Volume I, Appendix I) and the Structural Design Technical Memorandum (SDTM, Volume I, Appendix J), respectively. Attachment C discusses the selection of sorption parameters for cap modeling efforts.

1.0 UNDERLYING SEDIMENT CONSIDERATIONS

Underlying sediment concentration considerations have been updated to balance the cost-efficiency of RD with a conservative design approach. The main update in this 90% RD is the shift

Corporate Headquarters
11107 Sunset Hills Road, Suite 400
Reston, Virginia 20190
703-478-5186

from Project Area-wide concentrations to area-specific design, defined by certification units (CUs). CUs were developed in alignment with the Project-Area specific construction verification monitoring and remedy performance standards (EPA, 2025a; 2025b). This section also details parameters used for the underlying sediment in CapSIM modeling efforts for evaluating cap performance. These parameters include CU-specific chemical concentrations, sediment characteristics (e.g., total organic carbon [TOC], partitioning coefficients), and non-aqueous phase liquid (NAPL) observations.

Section 1.1 discusses area-specific concentrations used for each CU. Section 1.2 discusses site-specific linear partitioning coefficients. Section 1.3 discusses total organic carbon and the fraction of organic carbon inputs used. Section 1.4 includes a description of porewater concentrations used in modeling. Section 1.5 specifies the upwelling velocity used. Section 1.6 discusses NAPL observations.

1.1. CERTIFICATION UNIT AREA-SPECIFIC SEDIMENT CONCENTRATIONS

CU area-specific sediment concentrations evaluated in the cap design included validated and approved PDI ER and historical data from the SIB Project Area. CUs were determined using the following chemistry, constructability, and geotechnical considerations:

- **Size:** CUs comprise a 0.5-acre area for riverbank certification units (RCUs) and 1-acre area for cap certification units (CCUs) and dredge certification units (DCUs), in accordance with EPA's Portland Harbor Superfund Site Monitoring Guidelines (EPA, 2025b).
- **Outliers:** 95th percentile was calculated for all post-dredging analytes Project Area wide. If the CU-specific concentration exceeded this Project Area-wide 95th percentile concentration, it was considered an outlier and excluded from the cap alternative assignment matrix.
- **Requested Navigable Depths and Constructability:** Dredge prisms developed to address requested navigable depths were incorporated into the determination of CUs, alongside other constructability considerations.
- **Physical Design Considerations:** Considerations were made to include separation based on top capping layer (e.g., unamended habitat mix, erosion protection layer, revetment, and revegetation).
- **Dredge-to-RAL:** As detailed in the 90% RD Dredging Design Technical Memorandum (DDTM; Volume I, Appendix H), DCUs were defined for areas where spudding or other activities have the potential to compromise the cap and its performance.

Figure 1-1 shows all certification units, including 109 sediment CCUs, 30 RCUs, and 23 DCUs. As listed in Table 1-1, CCUs range in size from 0.73 to 1.00 acre, with an average size of 0.95 acre. RCUs range in size from 0.19 to 0.50 acre, with an average size of 0.48 acre. DCUs range in size from 0.73 to 0.99 acre, with an average size of 0.89 acre. As seen in both Figure 1-2 and Table 1-1, 83 CCUs will be (partially or fully) dredged prior to capping.

This cap design update was completed in accordance with EPA's Cap Design Criteria at Portland Harbor (EPA, 2025a) and EPA's Errata #4 for Portland Harbor Superfund Site Record of Decision

(EPA, 2025e). The 90% RD cap is designed to be protective of sediment cleanup levels (CULs) in the underlying sediment (EPA, 2025a). The cap design evaluation was completed by calculating CUL sediment-porewater equilibrium equivalents (CUL equivalent) using Project Area-specific sediment properties. Modeled porewater concentrations at the cap performance point (CPP) were compared to the groundwater/porewater CULs for informational purposes, but not used as a cap design evaluation metric (EPA, 2025a). As a result of this updated EPA guidance, a total of 27[1] sediment contaminants of concern (COCs) were used for cap design. Table 1-2 provides all CUL, remedial action level (RAL), and principal threat waste (PTW) threshold sediment criteria driving cap design, including calculated CUL equivalent concentrations.

As compared to Draft 50% RD, the calculation of 95th percentile sediment concentrations for each CU in the Pre-Final 90% RD included the following considerations:

- Sediment samples in 90% RD include data that was previously assigned as riverbank data, for samples collected below 13 feet (ft) North American Vertical Datum of 1988 (NAVD88), as seen in Attachment A;
- Riverbank data include samples collected from above 13 ft NAVD88, as seen in Attachment A;
- For each CU, geospatial analysis was conducted to assign all available sediment core data, including both PDI ER and historical data;
- The higher of duplicate sample results was used in the calculations, and the lower of the duplicate values was removed.
- Non-detect sample results were included in calculations at one-half the reporting limit;
- Sediment samples for location depths that will be dredged per the Dredging Design Tech Memo (DDTM; Volume I, Appendix H) to allow for placement of a 3-ft thick cap and 1-ft overdredge were excluded (list of samples available in Attachment B); and
- Sediment samples for location depths that will be partially dredged per the DDTM (Volume I, Appendix H) were included in calculations of sediment column concentrations remaining after dredging.

Uniform sediment concentration was assigned throughout the modeled sediment thickness for each CU using the following considerations:

- For CU concentrations below Project Area-wide 95th percentiles, the maximum concentration across all depth intervals for ROD Tables 17 and 21 analytes was used in the cap alternative assignments; and
- For CU concentrations exceeding Project Area-wide 95th percentiles, the Project Area-wide 95th percentile value was used instead of the maximum concentration to assign cap alternatives[2].

[1] From Field Sampling Plan (Appendix A PDI Work Plan; HGL, 2022), Section 4.2, page 4-2: “Chlorobenzene was not detected in surface or subsurface sediment samples from the SIB Project Area, and is not considered further."
[2] This approach prevents overdesigning based on outliers not considered representative of the CUs or overall Project Area conditions.

Table 1-3a summarizes Project Area-wide 95th percentile concentrations, as well as maximum CU concentrations detected at each sediment CCU. Table 1-3b summarizes Project Area-wide 95th percentile concentrations, as well as maximum CU concentrations detected at each riverbank RCU. Table 1-4 compares Draft 50% RD 95th percentile concentrations to 90% RD 95th percentile concentrations, with the main difference in the 90% RD being the inclusion of riverbank data (above and below 13 ft NAVD88) into overall concentration calculations. This table includes the relative percent difference (RPD)[3] between these percentile concentrations, including sample count and a 95 percent upper confidence limit (95% UCL) value of the sample mean for each analyte. An average of 1,375 samples evaluated for reported analytes, with counts ranging from 1,121 (tributyltin) to 1,519 (2,3,7,8-tetrachlorodibenzofuran). As expected, 95th percentile values of the COC concentrations are generally higher than the 95 percent UCL value for each COC.[4]

1.2. PROJECT AREA-ADJACENT LINEAR PARTITIONING COEFFICIENTS

The linear sorption model was applied to the sediment, sand, unamended habitat mix, and erosion protection materials, while Freundlich and Langmuir non-linear sorption isotherms were applied to the granular activated carbon (GAC) amendment. The linear sorption model is a widely accepted model for sorption of hydrophobic organic compounds onto sediments and natural organic matter (Karickhoff et al., 1979; Reible, 2023) as follows:

$$K_D = K_{oc} * f_{oc}$$

where K_D is a constant related to the organic carbon normalized partitioning coefficient, K_{OC} is organic carbon normalized partition coefficient, and f_{OC} is fraction of organic carbon primarily responsible for accumulation of contaminants to sediments (Goring CA, 1962; Reible, 2014).

K_D is also defined as:

$$K_D = \frac{C_{sed}}{C_{PW}}$$

where K_D is adsorption-desorption linear partitioning coefficient, C_{SED} is chemical concentration in the sediment at equilibrium and C_{PW} is chemical concentration in the porewater at equilibrium.

K_D values were calculated using Project Area-adjacent data, where available, and scientific literature already presented in the Draft 50% RD where Project Area-adjacent data wasn't available. An update from Draft 50% RD linear partitioning coefficients, arsenic values were updated in accordance with parameters available for commercially available material, as detailed in Attachment C.

Literature-derived values have limitations because they may not accurately represent Project Area-specific conditions. The primary concern is that using these K_D values could underestimate actual sediment porewater concentrations at the site. To address this limitation, Project Area-adjacent

[3] RPD is the ratio of the absolute difference between two values to the average of the two values, calculated as a percentage using the following formula: $(absolute\ difference/average) * 100\%$.
[4] Figures A-1 through A-49 visualize maximum concentrations in sediment and riverbank soil and indicate ROD Table 17 and 21 thresholds, where applicable.

values were used when available, as they better represent SIB Project Area conditions due to the physical proximity of these reference sites to the SIB Project Area. Project Area-adjacent data included the 2020 Transition Zone Water investigation from River Mile 9 West (RM9W) and 2023 porewater sampling data collected from EPA-led Cathedral Park, Fund-Lead (FL) 3, and FL 9 project areas (CDM Smith, 2025). RM9W is located on the opposite riverbank of the Willamette River from the SIB Project Area. FL 9 is upstream on the east riverbank between river miles (RM) 9 and 10. FL-3 is immediately downstream from the SIB Project Area, whereas Cathedral Park is further downstream (Figure 1-3). The following were excluded from Project Area-adjacent average calculations so they wouldn't incorrectly impact K_D values:

- RM9W T9-Duplicate results;
- RM9W T15-Duplicate results;
- Anomalously high sediment concentration for copper at T15 (a dataset outlier); and
- Supplemental PDI Site-Wide Partitioning Coefficient calculations from EPA FL-sites.

For K_D values not available from Project Area-adjacent data, literature values documented in Attachment C were used instead. An evaluation was conducted to assess the differences between literature-derived partitioning coefficients and Project Area-adjacent partitioning coefficients. Table 1-5 compares K_D values reported in the Draft 50% RD to 90% RD values using Project Area-adjacent K_D values, where data were available. As seen in Table 1-5, Project-Area specific K_D values were on average 134 percent higher as compared to the literature value (with RPD ranging from 8 percent [manganese] to 199 percent [polychlorinated biphenyl {PCB}-44]).

Because K_D and porewater concentration are inversely related, applying higher K_D values from Project Area-adjacent data to known sediment concentration yields a lower calculated porewater concentration compared to those used in the Draft 50% RD. This finding indicates that, on average, using lower literature-derived K_D values for other analytes provides more conservative (higher) porewater concentrations used for modeling efforts. These higher porewater concentrations lead to a more protective, and perhaps a more conservative, cap design. This finding also addresses the primary concern about whether literature-derived values adequately represent Project Area-specific conditions.

1.3. ORGANIC CARBON

The total organic carbon (TOC) results from SIB sediment samples of areas where it is anticipated that sediment will remain in place following dredging efforts were averaged and used as the fraction organic carbon (f_{OC}) of the sediment layer. Current dredging design efforts are presented in DDTM (Volume I, Appendix H). For intervals with partial dredging, TOC results for the interval were included in calculations. The dataset of 165 samples, including depth intervals not within the dredge prism area, used in the calculation of organic carbon is included in Table 1-6. The TOC value calculated as a result of this evaluation was 23,627 milligrams per kilogram (mg/kg) or 2.363 percent, which is reduced by 13.2 percent as compared to the value reported in the Draft 50% RD (2.697 percent). The 90% RD analysis was completed using this updated TOC value of 2.363 percent and f_{OC} of 0.02363.

1.4. POREWATER CONCENTRATIONS

Underlying sediment porewater equivalent concentrations were calculated for each CU based on the following parameters:

- Project Area-specific sediment f_{OC} discussed in Section 1.3.
- Equilibrium phase partitioning assumption;
- CU area-specific sediment concentrations for each CCU and RCU (Section 1.1); and
- Project Area-specific sediment K_D values (Section 1.2).

These model-calculated initial porewater concentrations were used as the bottom boundary concentrations. They were assumed to provide a constant supply of contamination, without depletion through time to integrate conservatism into the modeling efforts presented in Section 2.0.

1.5. UPWELLING VELOCITY

The Draft 50% RD utilized the highest 50-hour maximum specific discharge of 158 inches per year from Station 10A recorded during PDI ER efforts (1.1 centimeters [cm] per day) for upwelling velocity. For the 90% RD, refinements were completed to analyze the specific discharge Project Area-wide, and to delineate and assign upwelling velocity for "low discharge areas" to avoid applying overly conservative value for cap design.

For the Project Area-wide upwelling velocity, 50 inches per year (128 cm per year) was used in the 90% RD. As shown in Figure 1-4, this value applied Project Area-wide is still conservative, as the 95% UCL for all specific discharge measurements is 11 inches per year (28 cm per year). Utilizing value 4.6 times higher than this conservative estimate of the mean for Project Area-wide cap assignment provides for a reasonable level of conservatism to account for some limitations of the modeling approach (e.g., competitive sorption).

Groundwater modeling was completed and is included as an attachment to the Riverbank Design Technical Memorandum (RDTM) (Volume I, Attachment D). These modeling efforts, in conjunction with data from UltraSeeps deployed adjacent to riverbanks during the PDI, helped delineate "low discharge" areas within the SIB Project Area. These "low discharge" areas included all of the riverbanks (RCUs) and CCUs that are in revetment zone (CCUs 1 through 10 and 17), as well as CCUs adjacent to Swan Island uplands (CCU 79 through 86, 93, 94, and 100 through 104). To prevent a higher degree of conservatism than is appropriate, UltraSeep data of Swan Island-adjacent locations was evaluated and a value of 0.022 inches per day (20 cm per year) was selected for the cap in these low discharge areas. This is derived from the maximum rolling average of specific discharge for UltraSeep locations adjacent to Swan Island bank slopes (Appendix B of PDI ER; HGL, 2024a).

As documented in Draft 50% CDTM sensitivity analyses, the SIB SMA is subject to tidal influence, which was previously modeled using a diurnal oscillation period. However, the oscillating upwelling velocity did not impact the time-to-breakthrough as compared to steady-flow velocity, so only steady-flow velocity was used in the 90% RD.

1.6. NON-AQUEOUS PHASE LIQUID OBSERVATIONS

Visual screening observations of sheen and NAPL are documented in PDI ER Appendix A, Surface and Subsurface Sediment Sampling Data Report Table 2-5 (HGL, 2024a). The 90% RD NAPL Screening Technical Memorandum (Volume I, Appendix B) provides further detail regarding NAPL screening of SIB samples collected during the PDI. In summary, extensive sampling of SIB has provided relatively few locations where visible NAPL is present in the sediment; only 17 observations of NAPL (sheen) were noted in more than 1,200 sediment samples collected. These areas are well-delineated based on the extensive sampling completed for the Project Area. The RD anticipates that NAPL may be observed at the river surface during dredging, as the process of cutting and drawing material through the water column can result in the release of NAPL entrained within the sediment pore space to the water column, where NAPL less dense than water may float to the surface.

The 90% RD Water Quality Monitoring Plan (Attachment B of Construction Quality Assurance/Quality Control Plan [Volume II, Appendix N]) Section 3.2 and Table 1-2 provide triggers and actions to be taken during dredging if immediate NAPL releases due to sediment disturbance are encountered during RA. The Water Quality Monitoring Plan further states that the RA Contractor will be responsible for updating the plan prior to implementing construction activities to address any additional NAPL considerations. Additionally, the water treatment system required for dredged material water treatment will include a separations step that includes a NAPL adsorbent, as well as carbon filtration, so the NAPL released during the RA dredging is expected to be sufficiently controlled.

The dredge prisms designed for SIB will generally avoid a leave surface that intersects known NAPL-impacted sediments; and most sediment intervals with identified NAPL impacts will either be removed during dredging or remain under multiple feet of sediment that do not contain entrained NAPL. Figure 1-5 shows the locations of NAPL observations and intervals containing NAPL blebs that will be left in buried sediments post-dredge. As seen in Figure 1-5, this includes five locations of NAPL bleb observances (in grid cells D18, E33, E24, and F21). Post-dredge buried sediment intervals containing these blebs vary in depth from 0 to 1 ft (D18 and F21) to 7 to10 ft (E24).

Based on the design inputs listed above, CILs presented in this CDTM have been designed to address dissolved contaminant concentrations remaining at the post-dredge/pre-cap surface. It is unlikely that deeper intervals of sediment that contain sheen would produce any mobile NAPL at the mudline. However, a contingency capping plan is also being developed in the event that mobile NAPL evolves from the sediment surface after dredging activities have ceased.

Monitoring of the SIB surface water over time is the primary method of determining the need for the contingency cap. Observations of surface sheens will be continuously logged during the dredging work. The RA contractor will provide the observation records, including locations mapped of observed sheens. If multiple instances (multiple subsequent days) of discreet NAPL sheens are observed within a previously dredged area, the contractor will mobilize an aerial monitoring contractor (i.e. unmanned aerial vehicle [UAV] imaging) to document the precise locations of the NAPL source and the information will be used to estimate the aerial extent and mass of organoclay absorbent to be used for the contingency capping.

As stated in NAPL Screening Technical Memorandum (Volume I, Appendix B), for two core locations (E24 and E33) with observed NAPL within sample cores that intersect dredge leave surface, 3 inches of organoclay-containing granules will be placed within a 50-ft radius centered on these two locations after dredging and prior to capping. If any other mobile NAPL is encountered, a 3-inch cap with a small mass of organoclay (2 percent by weight) will be placed post dredging and prior to capping. The aerial monitoring data will provide additional semi-quantitative information to determine the appropriate absorbent mass and location to be placed for the NAPL contingency along with the designed CIL type for that CCU.

The Final 100% RD will include the details of the quantity of NAPL contingency cap materials required to be immediately available by the RA Contractor to enable contingency cap placement within 3 days of the determination of need during RA construction.

2.0 CHEMICAL ISOLATION LAYER CONSIDERATIONS

This section includes details regarding 11 different cap alternatives evaluated to select a protective CIL in Pre-Final 90% RD (Figure 2-1). These evaluated cap alternatives include the following CILs:

1. 1 ft (30 cm[5]) of unamended sand;
2. 6 inches (15 cm) of 5 percent[6] GAC-amended sand[7];
3. 1 ft (30 cm) of 5 percent GAC-amended sand;
4. 1 ft (30 cm) of 10 percent GAC-amended sand;
5. 1 ft (30 cm) of 20 percent GAC-amended sand;
6. 2.5 ft (75 cm) of 20 percent GAC-amended sand[8];
7. 0.8 inches (2 cm) of GAC reactive core mat – Tektoseal-AC[9].
8. 1.6 inches (4 cm) of Tektoseal-AC;
9. 0.8 inches (2 cm) of hybrid GAC reactive core mat and Tektoseal-HM (Zeolite-reactive core mat or similar);
10. 1.6 inches (4 cm) of GAC reactive core mat and Tektoseal-HM; and
11. 1.6 inches (4 cm) of Tektoseal-AC.

Modeling efforts were conducted using CapSIM for each cap alternative to identify selected constructible alternatives for each certification unit (CU), as detailed in Section 4.2. A selected

[5] CapSIM uses metric system in evaluations, whereas this RD is typically using imperial system. To overcome this discrepancy, lengths related to CIL are reported in both systems.
[6] Amendment percentage by weight.
[7] 5 percent GAC was determined to be the minimum constructible percentage.
[8] 2.5 ft (75 cm) CIL is maximum constructible alternative thickness from geotechnical considerations and GAC percentage from constructability considerations.
[9] This CDTM evaluated Tektoseal-AC GAC reactive core mat, and it refers to Tektoseal-AC specifically due to availability of material properties and sorption parameters. Any GAC-reactive core mat with similar or better performance for design analytes can be used during the RA Construction.

constructible alternative for each CU was selected to contain contamination and meet the remedial action objectives established in the ROD. The analysis accounted for the composition of the CIL required to control the migration of contaminants under fate and transport mechanisms such as advection, diffusion, dispersion, biodegradation, and bioturbation. The modeling was performed in accordance with the ROD (EPA, 2017), Remedial Design Guidelines and Considerations (RDGC; EPA, 2021b), U.S. Army Corps of Engineers (Palermo et al. 1998), and Sediment Cap Chemical Isolation Guidance (SD-1) (ITRC, 2023).

Section 2.1 discussed chemical transport modeling approach. Section 2.2 outlines modeling inputs. Section 2.3 summarizes results of the cap modeling. Section 2.4 discusses sensitivity analyses.

2.1. CHEMICAL TRANSPORT MODELING APPROACH

One-dimensional chemical mass transport modeling was conducted to determine the maximum contaminant concentration in underlying sediments that each cap alternative can contain for 100 years while remaining protective. The modeling was performed using CapSIM Version 4.2 modeling software (Shen et al, 2018; Reible, 2023) and following Sediment Cap Chemical Isolation Guidance (SD 1) guidance (ITRC, 2023). CapSIM modeling evaluated the containment time and effectiveness of the cap in maintaining a theoretical sediment solids concentration below sediment CUL, RAL, and PTW thresholds (EPA, 2021b) at CPP. Porewater concentrations at CPP were compared to groundwater/surface water CULs for informational purposes only (EPA, 2025b). The CapSIM-modeled values of porewater at the top of the CIL are used to evaluate a cap design's effectiveness by using a calculated sediment-porewater equilibrium value based on a sediment CUL for each COC and assuming that sediment contains the same sorption coefficient as the existing SIB sediment.

The CapSIM modeling software was used to predict the containment time of sediment concentrations below sediment thresholds. Evaluation was completed immediately above the chemical isolation layer at the CPP[10]. To complete the evaluation, a total of 59 individual contaminants and 5 COC totals (total carcinogenic polycyclic aromatic hydrocarbons [cPAHs], total DDx[11], total dioxins/furans, total polycyclic aromatic hydrocarbons [PAHs], and total PCBs), which were each evaluated both as summations and as modeled averages, were modeled. The analytes included in this evaluation are based on Table 17 of the ROD Errata #2 (EPA, 2020). Individual cPAHs and PAHs for which sediment data was available were modeled and summed over the 100-year model run time as another point of evaluation for total cPAHs and total PAHs[12]. In addition to total PCBs, all 10 homologs were represented by modeling 14 individual PCB congeners with high detection rates compared to the average detection rate across all PCB congeners and encompassing most of the published range of sorption coefficients to organic carbon

[10] Footnote 5 in the Draft 50% RD states that 90% Remedial Cap Design for SIB, the CPP will be 1 ft (30 cm) below the armoring layer consistent with RDGC Table 3-1 and included in the 50% RD considerations. However, EPA's Monitoring Guidelines footnote 9 states that "Immediately above the CIL may be a filter layer, an armor layer, or a habitat layer, depending upon the project-area-specific cap design" (EPA, 2025b), eliminating request for additional feet of sand to be placed between chemical isolation layer and armor/habitat layer. As a result, CPP remained positioned above chemical isolation layer, which now has erosion protection layer immediately on top.

[11] DDx = dichlorodiphenyldichloroethane (DDD) + dichlorodiphenyldichloroethylene (DDE) + dichlorodiphenyltrichloroethane (DDT)

[12] Total PAHs include summation of individual PAHs and cPAHs.

and GAC (Attachment C). These congeners were additionally summed over the 100-year model run time; however, as the 14 congeners do not represent all PCB detections, their summation analogue provides a more qualitative indicator of COC migration.

The cap performance is reported as a time-to-breakthrough. Time-to-breakthrough is defined as the time elapsed between cap installation and the first occurrence of a COC concentration in porewater that exceeds the relevant porewater concentration that is in equilibrium with SIB sediment containing that COC at the CUL concentration at the CPP. For example, a time-to-breakthrough of 80 indicates that a modeled COC would surpass the relevant sediment CUL equilibrium porewater concentration at the CPP 80 years after cap installation. The sediment CUL equilibrium porewater concentration was calculated within CapSIM using the sediment f_{OC} (Section 1.3) and the sediment sorption parameters, either K_{OC} or K_D, for each COC. The application sediment sorption parameters are discussed in Attachment C. Cap alternatives that did not experience a breakthrough within the modeled 100-year design life are reported to have a time-to-breakthrough of more than 100 years (100+).

The model input parameters were based on Project Area-specific data, where available, or literature values for comparable conditions. All chemical concentrations and 16 percent of physical capping material and sediment process input parameters were Project Area-specific input parameters. The Project Area-specific input values were supplemented by typical modeling values or available literature values for chemical and material properties. Sensitivity testing was performed to confirm that selected literature values produced a conservative cap design, as detailed in Section 2.4.

The CPP was selected to be at the top of CIL and below the erosion protection layer (EPL). Using the top surface of the CIL as the CPP ensures consistency in the evaluation of CIL performance for modeled COCs between the 11 cap alternatives. In all CIL alternatives evaluated, the CPP is below the conservative estimate of bioturbation reported in the ROD of 7.87 inches (20 cm) (EPA, 2017). Figure 2-1 illustrates the 11 conceptual CIL cap design alternatives modeled.

2.2. MODEL INPUTS

Input parameters were based on Project Area-specific data when available, such as upwelling velocities and sediment COC concentrations, along with information from scientific literature, including inputs from other regional CapSIM applications (Tables 2-1 and 2-2). Details on the development of the select model input parameters are provided in the following sections. The sources for material input parameters not discussed below are provided in Table 2-1.

2.2.1. Sorption Coefficients

The linear sorption model was applied to the sediment, sand, EPL, the zeolite amendment within Tektoseal-HM, and the bedding and armor stones. Properties of bedding and amor stone didn't impact cap design as the design is based on the performance at the CPP, and the CPP is located below bedding and armor stones for all evaluated CILs. Freundlich and Langmuir non-linear sorption isotherms were applied to the GAC amendment and the activated carbon within Tektoseal-AC. In the amended cap layer models, it was assumed that GAC and clean sand were evenly mixed within the chemical isolation layer and the above sorption isotherms were applied to their respective particles in the mixture.

The Freundlich and Langmuir sorption isotherms are frequently used to predict particle concentrations (q) from porewater concentrations (C) for activated carbon. The relation for the Freundlich isotherm is as follows:

$$q = K_f * C^{1/n}$$

where K_f is the adsorption capacity at unit concentration and 1/n (N) is the adsorption intensity (Reible, 2014).

The Langmuir isotherm is:

$$\frac{1}{q} = \frac{1}{q_m} + \left(\frac{1}{bq_m}\right)\left(\frac{1}{C}\right)$$

where q_m is the maximum adsorption capacity and b is the Langmuir constant (Patnukao et al., 2008).

For each COC, both parameters for the Freundlich or Langmuir isotherms originated from the same literature source of data. The selected sorption isotherm for each COC and material was dependent on the available literature. If multiple sorption isotherm equations were reported by one literature source, the isotherm with the better fit (higher R^2 value) to the literature data was selected. Attachment C includes detailed sources of specific sorption isotherms and sources applicable to each COC and modeled material. Table 2-2 summarizes selected inputs.

2.2.2. Fraction Organic Carbon in Capping Materials

Consistent with Draft 50% RD CDTM (HGL, 2025b), the sand present in the CIL and the habitat mix was assumed to have a f_{OC} of 0.1 percent. The modeled EPL materials were assumed to have a f_{OC} of 0.0 percent as this layer is not intended to provide chemical sequestration. The GAC amendment to the CIL is assumed to have a f_{OC} of 100 percent, which is the CapSIM default for the material (Reible, 2023).

2.2.3. Initial Concentrations

As described in Section 1.1, sediment concentrations remaining in CUs post-dredging were evaluated across the Project Area to determine 95th percentile sediment concentrations. This approach prevents outlier values from driving the cap assignment and leading to an overly conservative cap design. The modeled 95th percentile sediment concentrations are shown in Table 1-4 for most COCs, and include values used in Draft 50% RD and evaluates change between the Draft 50% and Pre-Final 90% RD values. Table 1-4 excludes modeled individual PCBs, PAHs, and cPAHs which are evaluated as a summed total. These COCs were each modeled using an even distribution of the 95th percentile sediment concentration of the total. Each of the 14 individual PCBs were modeled using an initial sediment concentration of 65.96 micrograms per kilogram (µg/kg), equivalent to 1/14 of the 95th percentile total PCB congener sediment concentration (923.4 µg/kg). All individual PAHs, excluding naphthalene, which has a calculated 95th percentile sediment concentration in Table 1-4, and cPAHs were modeled using an initial sediment concentration of 244.2 µg/kg, equivalent to 1/19 of the 95th percentile total PAHs sediment

concentration (4,640 µg/kg). This value was more conservative than using an even distribution of the 95th percentile total cPAHs sediment concentration (510 µg/kg) to model the seven individual cPAHs. Additionally, five modeled COCs (chromium, manganese, pentachlorophenol, vanadium, xylenes) have porewater CULs but do not have sediment CULs or sediment-porewater equilibrium equivalent and are therefore not included in Table 1-4. The modeled initial sediment and equivalent porewater concentrations for these five COCs are shown in the sensitivity modeling tables (Tables 2-4 through 2-14).

2.2.4. Bioturbation and Benthic Boundary Layer Condition

Consistent with Draft 50% RD, cap evaluation simulations modeled bioturbation using a conservative bioturbation layer thickness of 7.87 inches (20 cm) and a mass transfer coefficient of 0.1 cm per hour (876 cm per year) for all COCs. This mass transfer coefficient is one order of magnitude lower than the CapSIM default value (1.0 cm per hour) and falls within the EPA recommendation of using a mass transfer coefficient less than 0.5 cm per hour.

2.2.5. Model Input Summary

All chemical properties and partitioning coefficients are presented in Table 2-2 and discussed in Attachment C. The non-chemical specific model input parameters are presented in Table 2-1. This table is divided into sections that are specific to the sediment or capping materials and those that are general system parameters.

2.3. RESULTS OF CAP MODELING EVALUATION

The results of the cap chemical transport modeling indicate that a CIL composed of 1 ft (30 cm) of 5 percent to 20 percent GAC-amended sand will reliably contain the flux of all modeled COCs, including all Table 21 COCs. In accordance with EPA's Cap Design Criteria at Portland Harbor (EPA, 2025a), the time-to-breakthrough was based on time elapsed between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the calculated sediment-porewater CUL equivalent concentrations (Section 1.1; Table 1-2). The time-to-breakthrough of the 95th percentile sediment concentrations compared to the sediment-porewater CUL equivalent concentrations are summarized in Tables 2-3a and 2-3c for all modeled amended sand and reactive core mat alternatives, respectively. EPA's Cap Design Criteria at Portland Harbor (EPA, 2025a) further indicates that modeled porewater concentrations should be compared to the porewater (surface water and groundwater) CULs for informational purposes but not used as a cap design evaluation metric. The time-to-exceedance of surface water and groundwater CULs are included for all amended sand and Tektoseal cap alternatives in Tables 2-3b and 2-3d, respectively, for informational purposes only. Concentration profiles of the porewater and total solid concentrations compared to depth for each modeled cap alternative are included in Attachment D.

The CIL alternative composed of 1 ft (30 cm) of unamended sand (Cap Alternative 1), is not protective for every evaluated COC. Table 2-3a shows 21 exceedances of the calculated sediment-porewater CUL equivalent concentrations occur within 100 years following cap installation. Of the exceedances, seven occur within ten years following cap installation: summed PAHs (1 year), PCB-1 (1 year), summed PCBs (1 year), PCB-15 (3 years), mercury (6 years), dieldrin (7 years), and cadmium (8 years). Table 2-3b shows 27 exceedances of the informational ROD Table 17

porewater CULs. Of the COCs with porewater CUL exceedances, nine have an applicable calculated sediment-porewater CUL equivalent concentration that is not exceeded within the 100-year design life: aldrin, total and summed cPAHs, DDD, DDE, DDT, summed dioxins/furans, PCB-141, and tributyltin.

The CIL alternative containing 6 inches (15 cm) chemical isolation layer of 5 percent GAC-amended sand (Cap Alternative 2), is protective of all modeled COCs except for arsenic. The 100-year porewater concentration of arsenic is 16.4 micrograms per liter (µg/L), and porewater concentrations exceed the calculated sediment-porewater CUL equivalent concentration (8.02 µg/L) 77 years following cap installation (Table 2-3a). The maximum contained arsenic sediment concentration that can be reliably contained by Cap Alternative 2 for the 100-year design life is 6.625 mg/kg (6,625 µg/kg), which equates to 79th percentile of all post-dredge arsenic sediment data. For informational purposes only, arsenic porewater concentrations exceed the porewater CULs (0.018 µg/L) 55 years following cap installation (Table 2-3b).

The Tektoseal-HM reactive core mat product is designed for heavy metals, and sorption parameters to the amendment material are only available for arsenic, cadmium, chromium, copper, lead, mercury, and zinc (Table 2-2). Tektoseal products containing activated carbon (Tektoseal-AC) performed better than the Tektoseal-HM products for all COCs, including the targeted heavy metals (Tables 2-3c and 2-3d). One 2 cm layer of Tektoseal-AC is protective of all modeled COCs except for arsenic, BEHP, and cadmium. The 100-year porewater concentration of arsenic is 24.6 µg/L. Arsenic porewater concentrations exceed the calculated sediment-porewater CUL equivalent concentration (8.015 µg/L) 13 years following cap installation, and exceeded the informational porewater CULs (0.018 µg/L) 5 years following cap installation. The 100-year porewater concentration of BEHP is 0.0597 µg/L, below the surface water CUL (0.2 µg/L), and porewater concentrations exceeded the calculated sediment-porewater CUL equivalent concentration (0.05092 µg/L) 88 years following cap installation. The 100-year porewater concentration of cadmium is 0.0128 µg/L, below the groundwater CUL (0.094 µg/L), and porewater concentrations exceeded the calculated sediment-porewater CUL equivalent concentration (0.01018 µg/L) 20 years following cap installation. Adding a second 2 cm Tektoseal-AC layer increased the time-to-breakthrough for arsenic, BEHP, and cadmium to 33 years, 100+ years, and 68 years, respectively (Table 2-3c).

2.4. SENSITIVITY ANALYSES

Sensitivity analyses were performed for parameters that were determined to impact the design in Pre-Final 90% RD or were requested based on EPA's review of the Draft 50% CDTM. These analyses included the following:

- GAC amendment percentage;
- Chemical isolation layer thickness;
- Linear and nonlinear sorption parameters;
- EPL thickness;
- Bottom boundary condition;
- Cap consolidation;
- Sand and GAC settling separation; and
- CIL and sediment mixing.

Several of the model input parameters have uncertainty or variability associated with them, such as sorption parameters, bottom boundary conditions, cap consolidation, and variable settlement velocities. The sensitivity analyses were performed for the 95th percentile concentrations (Section 2.2.3) using a 1 ft (30 cm) thick sand cap amended with 5 percent GAC by weight, and including 1 ft (30 cm) of EPL (See Section 2.4.4) with Project Area-wide upwelling velocity of 50 inches per year (128 cm/year). The CPP for all sensitivity scenarios remained consistent (top of the CIL). The completed sensitivity analyses and the resulting differences in time-to-breakthrough and 100-year porewater concentrations are detailed in Tables 2-4 through 2-14. The reported percentage change in the 100-year porewater concentration resulting from the varied input parameter values shown in Tables 2-6 through 2-14 is the RPD.

2.4.1. GAC Amendment Percentage

The GAC amendment used in the sensitivity analyses base case was selected to be 5 percent by weight as that is the minimum constructible GAC amendment. The CIL alternatives evaluated included 10 percent and 20 percent GAC by weight, Cap Alternatives 4 and 5 respectively, and are applicable to CCUs with higher sediment concentrations than cannot be reliably contained by 5 percent of GAC-amended sand. Additionally, natural inconsistencies in mixing have the potential to increase or reduce the GAC percentage present in areas of an amended cap. A 1 ft (30 cm) thick sand cap amended with 2.5 percent GAC by weight was modeled to evaluate if contaminants would be contained in areas with a reduced amendment percentage.

For 1 ft (30 cm) CIL alternatives containing 5, 10, and 20 percent GAC amended sand and Project Area-wide upwelling velocity of 50 inches per year (128 cm per year), no modeled contaminants exceeded the sediment CUL-porewater equivalent concentration at the CPP for the 95th percentile concentrations. Copper and lead behaved inversely to other modeled contaminants, with higher 100-year porewater concentrations observed for higher modeled amendment percentages. Results of the analyses for the 95th percentile concentrations are presented in Table 2-4.

A comparison between the base case CIL, 1 ft amended with 5 percent GAC by weight, and a 1 ft thick sand cap amended with 2.5 percent[13] GAC by weight topped with 1 ft (30 cm) of EPL is included in Table 2-4. When modeled using the 95th percentile concentrations, a 100-year porewater concentration of 9.58 µg/L was observed for arsenic, exceeding the 8.02 µg/L sediment CUL-porewater equivalent concentration after 96 years. All other modeled COCs were effectively contained by a 1 ft (30 cm) thick sand cap amended with 2.5 percent GAC by weight. Consistent with the comparison between 1 ft (30 cm) 5 percent 10 percent, and 20 percent GAC-amended CIL alternatives, copper and lead behaved inversely to other modeled contaminants and lower 100-year porewater concentrations were observed for the cap alternative with the lower GAC amendment percentage.

2.4.2. Chemical Isolation Layer Thickness

To understand the potential impact of variability in the applied layer thickness of capping materials, the alternatives with CILs containing 6 inches (15 cm), 1 ft (30 cm) and 2 ft (60 cm) were compared (Table 2-5). Spatial discretization of 20 grids per layer was maintained. A 6-inch

[13] 2.5 percent-GAC amended sand was evaluated to understand potential implication of uneven distribution of GAC within sand.

(15 cm) CIL containing 5 percent GAC amended sand (Cap Alternative 2), is applicable to CCUs with lower sediment concentrations. When modeled using the 95th percentile concentrations, a 100-year porewater concentration of 16.4 µg/L was observed for arsenic, exceeding the 8.015 µg/L sediment CUL-porewater equivalent concentration after 77 years. The maximum contained concentration for 6-inch (15 cm) CIL containing 5 percent GAC-amended sand (Cap Alternative 2) is 6.63 mg/kg, a RPD of 34.7 percent compared to the 95th percentile sediment concentration (9.41 mg/kg). Summed cPAHs, driven by benzo(b)fluoranthene, and summed PAHs, driven by fluoranthene, behaved inversely to other modeled contaminants and lower 100-year porewater concentrations were observed for Cap Alternative 2. The 100-year porewater concentrations for benzo(b)fluoranthene and fluoranthene appear to be influenced primarily by the benthic boundary, therefore, the observed response to this sensitivity analysis may be different than if modeled with a higher initial sediment concentration or observed in situ. The porewater concentrations for other modeled contaminants, with the exception of copper, manganese, and zinc, showed a roughly proportional response to the halving of the chemical isolation layer thickness. A 2.5 ft (76 cm) CIL containing 20 percent GAC-amended sand (Cap Alternative 6), applies to CCUs with very high sediment concentrations. When compared to the results of 1 ft (30 cm) CIL containing 20 percent GAC-amended sand (Cap Alternative 5), similar conclusions can be drawn as from the comparison between 6 in (15 cm) and 1 ft (30cm) CIL alternatives containing 5 percent GAC-amended sand (Cap Alternatives 2 and 3, respectively) for the modeled COCs with 100-year porewater concentrations greater than 0.

2.4.3. Sorption Coefficients

The derivation of the Freundlich and Langmuir sorption parameters for organic carbon, activated carbon, sediment, and granular capping materials that were used in modeling is described in Attachment C. Sensitivity testing completed to date found the model to be very sensitive to changes in the nonlinear sorption parameters. According to ITRC guidance, “if site-specific testing is not conducted, literature values may be used, although isotherms derived from the literature may not account for particle size differences (e.g., GAC vs. powdered activated carbon), competition of sorption sites for the full suite of chemicals present in the sediment porewater at a site, the potential for fouling or dechlorination and the formation and precipitation of metal sulfides, or the competitive effects of natural organic matter (NOM). It may be appropriate to reduce the sorptive capacity of activated carbon by a factor of 2 to 5 to account for the effects of NOM” (ITRC, 2023). As a sensitivity analysis, the K_f and q_m values were reduced by one order of magnitude for all modeled COCs. This sensitivity analysis evaluates if the available literature values over-represent the sorption of the modeled COCs due to differences from experimental conditions such as the specific capping materials acquired or the geochemical conditions in SIB. When modeled using the 95th percentile concentrations, a 100-year porewater concentration of 24.0 µg/L was observed for arsenic, exceeding the 8.02 µg/L sediment CUL-porewater equivalent concentration after 38 years, and a 100-year porewater concentration of 0.0134 µg/L was observed for cadmium, exceeding the 0.0102 µg/L sediment CUL-porewater equivalent concentration after 39 years (Table 2-6). The time-to-breakthrough for all other COCs remained greater than 100 years. Copper did not exhibit a sensitivity to the reduced sorption parameter (q_m) and the 100-year porewater concentration was unchanged. Lead and manganese were minimally sensitive to the reduced sorption parameters, with 100-year porewater concentration changes having RPDs of less than 1 percent. Summed cPAHs, driven by benzo(b)fluoranthene, behaved inversely to other modeled contaminants and lower 100-year porewater concentrations were observed for the reduced sorption

parameter sensitivity analysis. The 100-year porewater concentrations for benzo(b)fluoranthene appear to be influenced primarily by the benthic boundary, therefore, the observed response to this sensitivity analysis may be different than if modeled with a higher initial sediment concentration or observed in situ.

Three modeled COCs, BEHP, phenanthrene, and PCB-15, utilize a Freundlich parameter (1/n) that is greater than 1 (Attachment C). To evaluate the conservativism of these literature values, BEHP and PCB-15 were modeled with the parameter (1/n) set to 1.0, exhibiting linear partitioning. For the sensitivity analysis, the Freundlich sorption parameters published in Walters & Luthy (1984) were utilized for phenanthrene (K_f = 1.653E+07; 1/n = 0.406). When modeling the reduced Freundlich parameter (1/n), the 100-year porewater concentration of BEHP was reduced from 7.25E-04 µg/L to 2.98E-20 µg/L and was unchanged from 0 µg/L for phenanthrene and PCB-15 (Table 2-6). The time-to-breakthrough for the impacted COCs remained greater than 100 years.

Linear sorption parameters for all COCs were independently varied as sensitivity analyses to understand the impact of linear sorption coefficient changes on overall cap performance. The organic carbon partitioning coefficient, K_{OC}, was multiplied by 1.2 and 0.8 for all organic COCs (Table 2-7). This scaling factor creates a range of K_{OC} values for each COC that generally encompasses most or all of the range of literature K_{OC} values. K_{OC} affects the sorption to all capping materials containing organic carbon, which includes sediment and capping sand, except for metals and the COCs with Project Area-adjacent K_D values for sorption to sediment (Table 1-5). Additionally, K_{OC} is utilized for sorption to GAC for diesel. When modeling 1.2 times K_{OC}, the 100-year porewater concentration of BEHP was reduced from 7.25E-04 µg/L to 2.63E-05 µg/L, an RPD of 186 percent, and diesel decreased from 7.36E-14 µg/L to 0 µg/L, an RPD of 200 percent. When modeling 0.8 times K_{OC}, the 100-year porewater concentration of BEHP increased from 7.25E-04 µg/L to 9.64E-04 µg/L, an RPD of 28.3 percent, and diesel increased from 7.36E-14 µg/L to 5.61 µg/L, an RPD of 200 percent. Tributyltin exhibited a similar responsiveness to diesel; when modeling 1.2 times K_{OC}, the 100-year porewater concentration was reduced from 7.91E-10 µg/L to 0 µg/L, an RPD of 200 percent, and when modeling 0.8 times K_{OC}, the 100-year porewater concentration increased to 8.67E-04 µg/L, an RPD of 200 percent. The linear partitioning coefficient for metals to capping sand, K_D, was multiplied by 1.2 and 0.8 for all modeled metals (Table 2-8). This scaling factor is consistent with the K_{OC} sensitivity analysis. Manganese exhibited the least sensitivity of all metals with non-zero 100-year porewater concentrations to the change in K_D to sand. When modeling 1.2 times K_D, the 100-year porewater concentration was reduced from 1.20E+04 µg/L to 1.19E+04 µg/L, an RPD of 0.837 percent, and when modeling 0.8 times K_D, the 100-year porewater concentration increased to 1.21E+04 µg/L, an RPD of 0.830 percent. Lead exhibited the highest sensitivity of all metals with non-zero 100-year porewater concentrations to the change in K_D to sand. When modeling 1.2 times K_D, the 100-year porewater concentration was reduced from 6.79E-09 µg/L to 4.66E-10 µg/L, an RPD of 174 percent, and when modeling 0.8 times K_D, the 100-year porewater concentration increased to 1.35E-07 µg/L, an RPD of 181 percent. The time-to-breakthrough for the impacted COCs remained greater than 100 years.

The linear partitioning coefficient to sediment for metals and COCs with Project Area-adjacent K_D values was additionally multiplied by 1.2 and 0.8 for all applicable COCs (Table 2-9). Diesel exhibited the least sensitivity of all COCs with non-zero 100-year porewater concentrations to the change in K_D to sediment. When modeling 1.2 times K_D, the 100-year porewater concentration

was reduced from 7.36E-14 µg/L to 6.70E-14 µg/L, an RPD of 9.39 percent, and when modeling 0.8 times K_{OC}, the 100-year porewater concentration increased to 8.28E-14 µg/L, an RPD of 11.8 percent. Manganese exhibited the highest sensitivity of all COCs with non-zero 100-year porewater concentrations to the change in K_D to sediment. When modeling 1.2 times K_D, the 100-year porewater concentration was reduced from 1.20E+04 µg/L to 1.00E+04 µg/L, an RPD of 18.2 percent, and when modeling 0.8 times K_D, the 100-year porewater concentration increased to 1.51E+04 µg/L, an RPD of 22.9 percent. The time-to-breakthrough for the impacted COCs remained greater than 100 years.

The linear partitioning coefficient for metals to the EPL, K_D, was multiplied by 1.2 and 0.8 for all modeled metals (Table 2-10). This scaling factor is consistent with the K_{OC} sensitivity analysis. The partitioning coefficient was additionally multiplied by 2.5 and 0.5 to encompass the greater uncertainty associated with utilizing K_D values published for sand to also model sorption to larger gravels and erosion protection materials. Of the metals with non-zero 100-year porewater concentrations, lead exhibited the highest sensitivity to the change in K_D to the EPL. When modeling 1.2 times K_D, the 100-year porewater concentration was reduced from 6.57E-09 µg/L to 6.05E-09 µg/L, an RPD of 8.24 percent, and when modeling 0.8 times K_D, the 100-year porewater concentration increased to 7.21E-09 µg/L, an RPD of 9.29 percent. When modeling 2.5 times K_D, the 100-year porewater concentration was decreased from 6.57E-09 µg/L to 4.00E-09 µg/L, an RPD of 48.6 percent, and when modeling 0.5 times K_D, the 100-year porewater concentration increased to 8.45E-09 µg/L, an RPD of 25 percent. The time-to-breakthrough for the impacted COCs remained greater than 100 years.

2.4.4. Erosion Protection Layer Thickness

As discussed in Section 3.8, the CIL will have 2 ft of EPL[14] placed on top of CIL (see Figure 2-1). Although no substantial change in performance was expected due to negligible sorption of COCs to this type of material, comparison of performance of 1 ft to 2 ft of EPL thickness was evaluated for 6 inches (15 cm) and 1 ft (30 cm) of 5 percent GAC-amended sand (Cap Alternatives 2 and 3, respectively) (Table 2-11). Spatial discretization of 20 grids per layer was maintained, and the CPP remained at the top surface of the CIL. As expected, for 1 ft of 5 percent GAC-amended sand (Cap Alternative 2), with 2 ft of EPL a negligible increase in 100-year porewater equivalent concentrations was observed for arsenic compared to 1 ft of EPL, which increased from 0 µg/L to 7.23E-20 µg/L, and acenaphthylene, which increased from 0 µg/L to 1.29E-16 µg/L. The 100-year porewater equivalent concentrations of benzo(b)fluoranthene, copper, summed cPAHs, lead, fluoranthene, manganese, summed PAHs, and zinc all decreased with RPDs between 0.837 and 200 percent. The time-to-breakthrough for all COCs remained greater than 100 years. For 6 inches (15 cm) CIL containing 5 percent GAC-amended sand (Cap Alternative 3), a negligible increase in 100-year porewater concentrations was observed for summed PAHs, driven by fluoranthene, with sensitivity 100-year porewater concentrations of 9.55E-18 µg/L and 9.52E-18 µg/L, respectively. The only notable difference for Cap Alternative 2 was 100-year porewater equivalent concentration of arsenic, which decreased from 16.4 µg/L (1 ft of EPL) to 15.1 µg/L (2 ft of EPL), an RPD of 8.25 percent, and the time-to-breakthrough was extended from 77 to 79 years for sensitivity analysis containing 1 ft (30 cm) of EPL and EPL thickness used in 90% RD. The time-

[14] In the Pre-Final 90% RD Design Drawings, what is referred to as EPL consists of either 2 ft of rounded gravel or 18 inches of angular rock with 6 inches of unamended sand on top as a habitat layer.

to-breakthrough for all other COCs remained greater than 100 years. The design impact of this evaluation is that sensitivity analyses performed with 1 ft (30 cm) of EPL are more conservative than cap performances for 90% RD, which all contain 2 ft (60 cm) of EPL (Figure 2-1).

2.4.5. Bottom Boundary Condition

The bottom boundary condition type was conservatively assumed to be a fixed concentration. The flux-matching bottom boundary condition is commonly used to model advective and reactive transport (Reible, 2023). Sensitivity testing using the flux matching bottom boundary condition type and matched boundary concentrations set to the calculated equilibrium porewater concentration in the sediment only affected the 100-year porewater concentration for arsenic, which increased from 0 µg/L to 1.69E-19 µg/L, an RPD of 200 percent (Table 2-12). The time-to-breakthrough for all COCs remained greater than 100 years. The sensitivity analysis was repeated for 6 inches (15 cm) CIL containing 5 percent of GAC-amended sand (Cap Alternative 2). Only the 100-year porewater concentration for manganese was affected, which decreased from 1.22E+04 µg/L to 1.21E+04 µg/L, an RPD of 0.823 percent (Table 2-12). The time-to-breakthrough remained 77 years for arsenic and greater than 100 years for all other COCs.

2.4.6. Consolidation of Underlying Sediment

The consolidation depth and time to 90 percent consolidation for all modeled cap alternatives was modeled using the predicted Project Area-specific maximum consolidation of 29.2 cm and 1.2 years, respectively. Due to differences in selected constructible alternatives (Section 4.1), consolidation values will differ across the SIB Project Area. As a sensitivity analysis, the maximum consolidation and time to 90 percent consolidation were doubled both independently and collectively (Table 2-13). All combinations of the sensitivity analysis had an insignificant impact on overall cap performance. For example, all combinations reduced the 100-year porewater concentration of fluoranthene from 1.09E-17 µg/L to 0 µg/L, both values negligible. The 100-year porewater concentrations of benzo(k)fluoranthene were reduced from 2.25E-20 µg/L to 0 µg/L from the independently varied consolidation parameters, and to 1.69E-20 µg/L for the collectively varied consolidation parameters, all values being effectively zero. The time-to-breakthrough for all COCs remained greater than 100 years. Based on the consolidation settlement analysis discussed in Section 4.2.2 of the GDTM (Volume I, Appendix I), additional sensitivity analysis was completed to evaluate 20 inches (50.8 cm) consolidation over 2.5 years. As seen in Table 2-13, the difference is also negligible, with a maximum difference of porewater values greater than parts per quadrillion range of 0.41% (e.g., 0.000725 µg/L vs 0.000728 µg/L for BEHP in porewater). The time-to-breakthrough for all COCs remained greater than 100 years.

2.4.7. Sand and GAC Settling Separation

CapSIM assumes the sand and GAC in GAC-amended sand alternatives are uniformly mixed. Although this challenge is expected to be addressed using proven proprietary capping broadcasting technology, sensitivity analysis was completed to understand the impact of potential sand and GAC settling separation during cap installation. It is anticipated that if this separation was to happen, the resulting CIL would have more GAC near the surface of the CIL and less near the surface of

the sediment. As a sensitivity analysis, the sand and GAC materials were modeled as two separate layers with the layer thickness determined by the volume fraction of each material (Table 2-14). The 1 ft (30 cm) CIL containing 5 percent GAC-amended sand (Cap Alternative 3) was first modeled assuming 2 lifts performed during installation, resulting in alternating layers of 0.92 inches (2.34 cm) of GAC on top of 4.98 inches (12.66 cm) of sand. Of the modeled COCs, only manganese and benzo(g,h,i)perylene were observed to have an increase in 100-year porewater concentrations for the separated materials, from 1.20E+04 µg/L to 1.21E+04 µg/L and from 0 µg/L to 7.56E-20 µg/L, respectively. The 100-year porewater concentration for benzo(g,h,i)perylene appears to be influenced primarily by the benthic boundary; therefore, the observed response to this sensitivity analysis may be different if modeled with a higher initial sediment concentration or observed in situ. The time-to-breakthrough for all COCs remained greater than 100 years.

The 1 ft (30 cm) CIL containing 5 percent of GAC-amended sand (Cap Alternative 3) was then modeled assuming 3 lifts are performed during installation, resulting in alternating layers of 0.61 inches (1.56 cm) of GAC on top of 3.32 inches (8.44 cm) of sand (Table 2-14). Of the modeled COCs, only manganese and PCB-1 were observed to have an increase in 100-year porewater concentrations for the separated materials, from 1.20E+04 µg/L to 1.21E+04 µg/L and from 0 µg/L to 1.49E-17 µg/L, respectively. The time-to-breakthrough for all COCs remained greater than 100 years.

2.4.8. CIL and Sediment Mixing

All cap alternatives were modeled assuming no mixing occurs between the underlying sediment and the applied capping materials. Depending on the compactness of the surface sediment onto which the capping material is applied, there may be mixing of the CIL and the underlying sediment. As a sensitivity analysis, a 1.98-inch (5 cm) layer depicting an even mixture of 50 percent sand and GAC and 50 percent sediment was modeled (Table 2-15). The unmixed CIL and sediment layers were both reduced to 10.8 inches (27.5 cm) to maintain the 3 ft (90 cm) total model thickness. Spatial discretization of 20 grids per layer was maintained, and the CPP remained at the top surface of the CIL. Initial loading concentrations were assigned to the sediment and porewater components of the mixture, equivalent to the initial conditions of the underlying sediment. A negligible decrease in 100-year porewater concentrations was observed for diesel, which decreased from 7.36E-14 µg/L to 6.06E-14 µg/L, an RPD of 19.4 percent, and tributyltin, which decreased from 7.91E-10 µg/L to 6.35E-11 µg/L, an RPD of 170 percent. The 100-year porewater concentrations for BEHP, copper, lead, manganese, and zinc all increased in response to this sensitivity analysis with RPDs between 0.830 and 64.3 percent. The 100-year porewater concentration for summed cPAHs, driven by benzo(b)fluoranthene, and summed PAHs, driven by benzo(g,h,i)perylene and fluoranthene, all varied in this sensitivity test, however, the porewater concentration appears to be influenced primarily by the benthic boundary, therefore, the observed response to this sensitivity analysis may be different than if modeled with a higher initial sediment concentration or observed in situ. The time-to-breakthrough for all COCs remained greater than 100 years.

The sensitivity analysis was repeated with a 4-inch (10 cm) layer depicting an even mixture of 50 percent sand and GAC and 50 percent sediment (Table 2-15). The unmixed CIL and sediment layers were similarly both reduced to 25 cm to maintain the 90 cm total model thickness. An increase in 100-year porewater concentrations was only observed for summed cPAHs, driven by

benzo(b)fluoranthene, and summed PAHs, driven by fluoranthene. The 100-year porewater concentrations for BEHP, cadmium, copper, diesel, lead, manganese, tributyltin, and zinc all increased in response to this sensitivity analysis with RPDs between 0.830 and 200 percent. The time-to-breakthrough for all COCs remained greater than 100 years.

2.4.9. Summary of Sensitivity Testing

The preceding sensitivity analyses reiterate the previous findings that, for an amended cap, the majority of considered COCs are sensitive to changes in the following parameters:

- GAC amendment percentage,
- Amended CIL thickness, and
- Sorption parameters.

With 1 ft (30 cm) of 5 percent GAC-amended sand (Cap Alternative 3), the 95th percentile sediment concentrations are contained far enough below CPP that, despite some high RPD changes in 100-year porewater concentrations, cap breakthrough was generally not observed in the sensitivity analyses.

3.0 PHYSICAL DESIGN CONSIDERATIONS

Two key physical factors considered for cap design were geotechnical stability and erosion protection. The cap must be structurally stable, which requires analysis of geotechnical conditions presented in the GDTM (Volume I, Appendix I). Additionally, an EPL is necessary to prevent damage to the CIL. A preliminary analysis was presented in Draft 50% RD (HGL, 2025b). This CDTM describes climate change evaluations, bank erosion protection, and 90% RD post-construction elevations. Sections 3.1 to 3.7 describe the hydrodynamic modeling and analysis for various forces in SIB. Section 3.8 presents Pre-Final 90% RD erosion protection requirements.

3.1. RIVER CURRENTS IN SWAN ISLAND BASIN

Erosive forces created by river currents during a 100-year flood were evaluated, including climate change considerations in the form of potential increases in river discharge and sea level rise. The inclusion of climate change effects in river hydrodynamics (for the purpose of erosion protection) requires an understanding of sea level rise effects at the Project Area and increased discharges. The United States Geological Survey (USGS) model of the Columbia and Willamette Rivers (Wherry et al., 2018), developed to analyze sea level rise effects, was executed to provide local boundary conditions for use with the SIB validated nested river model described in the Cap Evaluation Technical Memorandum (HGL, 2025a).

3.1.1. Summary of USGS Climate Change Model and Simulations (Work by Others)

The USGS developed a hydrodynamic model application using the Delft3D Flexible Mesh (Deltares, 2023) modeling platform to simulate the effects of plausible extreme high water during the 2030 to 2059 period. The USGS included the Columbia River from the Pacific Ocean to Bonneville Dam at RM 145 in their model. The USGS also included the Willamette River from the Columbia River confluence to Willamette Falls at RM 26.2 in their model. The USGS included

five upstream river boundaries and one downstream ocean tidal boundary in their model. The USGS calibrated their model for two historical periods: (1) January 15 to February 28, 1996, and (2) April 12 to July 12, 1997.

Future conditions simulated by the USGS in their model were based on climate science data developed by the U.S. Army Corps of Engineers (USACE) and others. These conditions included future streamflow and coastal ocean water levels. The hypothetical, extreme but plausible, upstream boundary was developed by the USGS by scaling up the hydrographs from the 1996 flood. The USGS determined scaling factors by comparing the peak flow rankings determined from flood frequency analyses of historical unregulated periods and 2040s simulated unregulated winter streamflow. The comparison resulted in the USGS scaling up the Columbia River hydrograph by 40 percent and scaling up the Willamette River, Sandy, Lewis, and Cowlitz River hydrographs by 20 percent in their model.

The water surface elevations imposed at the Pacific Ocean Boundary comprise three parts: (1) mean sea level, (2) storm surge deviations from mean sea level, and (3) deviations from mean sea level because of astronomical tides. The following low, intermediate, and high scenarios were considered for projections of future changes in mean sea level: 0.0 meter (USACE low scenario for sea level rise anticipated by the year 2040), 0.25 meter (USACE intermediate scenario for sea level rise anticipated by the year 2094), and 1.0 meter (USACE high scenario for sea level rise anticipated by the year 2088).

All scenarios described above were simulated using the USGS model as part of 90% RD, to provide a full range of conditions that would encompass worst-case design velocities for cap design. The results of the USGS model included water levels and discharges at all locations in the domain from the Pacific Ocean to the upstream boundaries at Bonneville Dam/Willamette Falls. These modeling results were used as boundary conditions for local 3D hydrodynamic modeling simulations using the SIB validated nested 3D model (HGL, 2025b).

3.1.2. SIB Nested River Model Simulations with USGS Climate Change Model Boundary Conditions

The SIB validated nested model (structured Delft3Dv4; HGL, 2025b) was employed to estimate bed shear stress and velocity at SIB, while considering the effects of climate change. Boundary conditions for the SIB validated nested model included daily inflow hydrographs and water levels for both the upstream and downstream sections of the Willamette River, taken from results of the USGS Climate Change Model. The upstream conditions were developed using hydrographs from the USGS climate change model boundary conditions (SLC Scenarios). Water levels at the downstream end of the SIB validated nested model were obtained by executing the USGS model described above and extracting time histories.

Maximum velocities in the SIB occurred at the interface with the main river. The maximum near-bed velocity in SIB of 6.9 ft per second resulted from the SLC of 0 ft (0.0 meter) scenario, which is approximately 3 percent higher than the maximum near-bed velocity for the SLC of 3 ft (1.0 meter) scenario. Therefore, the future flood event with increased discharges, but without any sea level rise, generates the largest bed shear stress in the project area (approximately 6.1 Pascals [Pa]). Figure 3-1 shows the maximum bed shear stress values from the river modeling simulations, to be

used in cap erosion protection design for all three SLC Scenarios. The shear stresses from river currents, even considering increased river discharges and sea level rise, only control cap erosion protection design in a very small portion of SIB on the main river. These bed shear stresses were added to the overall maximum bed shear stress data from all hydrodynamic forces, and material size requirements were calculated (see Section 3.7.1).

3.2. WIND-WAVES

Wind-waves were evaluated and simulated for 100-year wind conditions during the Draft 50% RD (HGL, 2025b). The inputs for this memorandum were consistent with those in the Draft 50% RD except for the elevation surface used in the model, which represented post-construction conditions in the Pre-Final 90% RD.

Wave conditions were analyzed at various transects around SIB. The largest waves were predicted around the entrance to SIB, which is exposed to longer fetches within the Willamette River. Logically the smallest wave heights were predicted at the head of the SIB. Near Vigorous Dry Dock along the Willamette River, significant wave heights reach up to 2.7 ft with peak periods of 3.2 seconds. Near the entrance of the basin, at U.S. Coast Guard Pier, significant wave heights reach up to 2.4 ft and peak periods of 2.8 seconds. Midway through SIB, at the Port of Portland Dredge Base, significant wave heights reach up to 1.6 ft and peak periods of 2.8 seconds. Significant wave heights reach only 1.1 ft and peak periods of 1.9 seconds at the Swan Island Boat Ramp at the head of the SIB.

Figure 3-2 shows the maximum 100-year significant wave heights during 100-year winds from all directions. Figure 3-2 was generated by finding the largest wave height in each grid cell from all the different simulations with varying wind directions. No substantial changes in wave conditions resulted from those predicted during the BODR (HGL, 2024b), since SIB is relatively deep in comparison to wind-wave heights. Shear stresses from waves were calculated on the slopes, although shear stresses were not used in the analysis of slope protection design (design methods for slope protection use wave parameters, not shear stresses). The wave-induced shear stresses, which are consistent with prior calculations, are included in the combined bed shear stress model, and are clearly visible along the shoreline (see Section 3.7.1).

As previously noted in the Draft 50% RD, vessel wakes do not control erosion protection design anywhere in SIB (HGL, 2025b) and were not considered further in the Pre-Final 90% RD.

3.3. PROPELLER WASH

High-frequency (30-second) Automatic Information System (AIS) data collection was commissioned for the SIB and a portion of the river surrounding the SIB from February 21 to May 27, 2022 (RDWP; HGL, 2025a). Consistent with Draft 50% RD (HGL, 2025b), these data were used to model propeller wash (prop wash) from all vessel traffic, resulting in a bed shear stress map suitable for conceptually sizing erosion protection materials.

During Pre-Final 90% RD, this analysis was updated using the same methodology, but with revised input data and more conservative assumptions. A post-construction elevation surface (after dredging and capping) was used, rather than the existing riverbed elevations. In some areas, this resulted in shallower water and more potential for prop wash to induce erosive forces on the cap.

The same vessel traffic was assumed in the analysis, since the prediction of future vessel characteristics is not feasible. However, additional conservatism was included by assuming that all vessels utilize 100 percent of the applied power in the prop wash calculations. This approach is consistent with, but more conservative than, recommendations in the Remedial Investigation/ Feasibility Study (RI/FS; EPA, 2016). Further modifications have been made through refinement of vessel traffic data such as confirming realistic underkeel clearances during the actual transits.

Bottom velocity was computed on the riverbed (unified elevation model) with time-varying river water levels at every 3.2 ft (1 meter) along each passing vessel route. Bottom velocities were computed on the riverbed using the post-construction surface elevations from the 90% RD. Bed shear stress was computed using near-bed velocity and shear stress according to Maynord (2000). Results indicate that prop wash generates maximum bed shear stresses of approximately 60 Pa in the main navigation areas when assuming 100 percent applied power for all vessels (see Figure 3-3). An example bed shear stress calculation is also shown in Figure 3-3 (inset) for a single vessel position. These bed shear stresses were added to the overall maximum bed shear stress data from all hydrodynamic forces, and material size requirements were calculated.

3.4. DRY DOCK ACTIVITIES

Dry dock operations were analyzed and documented in the Cap Evaluation Technical Memorandum (HGL, 2025a), including raising and lowering of the dry docks, and ballast water dewatering (water jet discharges). During Pre-Final 90% RD, this analysis was updated using the same methodology and input data, but a post-construction surface (elevations after proposed dredging and capping) was inserted. While the position of the dry docks in the previous analysis was determined based on the shallowest point in the existing bathymetry, the updated bathymetry with the post-construction surface allowed the dry docks to be positioned at their intended navigation depths, with 1-ft (0.3-meter) clearance above the bed (cap). This assumption results in more of the side slopes of the dredge cut being exposed to the dewatering jets. The simulated raising and lowering of the dry docks that were performed during the BODR resulted in negligible bottom shear stresses; therefore, these simulations were not repeated for the Pre-Final 90% RD.

Figure 3-4 shows peak bed shear stresses from all simulations performed for all dry docks. Shear stresses resulting from bottom velocities imposed by dry dock operations were computed in the Draft 50% RD and Pre-Final 90% RD in a slightly different manner (using updated bottom material roughness) more consistent with shear stress calculations for river currents, which govern erosion protection design in the area. Ballast water intake/discharge jets are likely to impinge on the slopes of the dredge cuts and bulkheads and could also interact with other dry docks if they happen to be in the lowered position at the same time. Dewatering jets would cause peak bed shear stress of approximately 3.6 Pa on the dredged slope on the south side of Vigorous Dry Dock. At Dry Dock 5 the dewatering jets would result in a peak bed shear of 0.7 Pa directly below the dry dock, and up to 1.9 Pa along the dredged slope east of the dry dock. Dry Dock 3 operations do not generate significant bed shear stresses. These shear stresses were combined with the peak shear stresses Project Area-wide from other physical processes and used for erosion protection design.

3.5. OUTFALLS

This section contains physical design considerations as they pertain to City of Portland (City) outfalls in Section 3.5.1, and non-City outfalls in Section 3.5.2.

3.5.1. City Outfalls

Erosion protection requirements around outfalls are the most robust of any location in SIB. During peak rainfalls, outfall discharges result in large water velocities and bed shear stresses, which are presently resisted by deteriorated riprap and/or concrete headwalls surrounding the outfalls. Discharges were estimated previously during the BODR (HGL, 2024b) using the Pacific Coast Stormwater Management Manual (PCSWMM) stormwater system model (advanced modeling software for EPA Stormwater Management Manual (SWMM) 5 stormwater, wastewater, and watershed systems), which was created to represent the City outfalls.

The analysis included 100-year flows, and climate change-related increases in peak rainfall intensity. 100-year outfall flows were re-evaluated, because other data sources are relatively outdated and under-conservative (e.g., NOAA Precipitation Atlas). Extreme value analysis was performed using data from the 7-year time history of discharges from PCSWMM, using a Fisher-Tippet Type I statistical distribution that best fit the annual discharge maxima.

The time history of discharge was relatively short for use in preparation of 100-year predictions. Therefore, additional safety factors were incorporated into the scour protection design (see Section 3.7). Increased rainfall intensity to represent Year 2100 was taken from the Climate Impacts Group at the University of Washington. To project to the Year 2100 (Climate Impacts Group data only extend to 2080), a polynomial fit was applied to the available rainfall intensity future prediction data. Rainfall intensity is estimated to increase by 83 percent by the Year 2100. The polynomial fit quality is further discussed during the discussion of the outfall velocities below.

The 100-yr discharges were scaled linearly to incorporate peak rainfall intensity increases under climate change. The PCSWMM modeling was not repeated for the higher rainfall intensity, since the drainage areas are small and changes in peak rainfall intensity correlate well with changes in peak outfall discharges. Future changes in temperature, evaporation, and wind were not considered since the ultimate goal of the analysis is concrete mattress scour protection design, for which these factors are negligible.

The computational fluid dynamics (CFD) model (Flow3D) was used to simulate M1, M2, M3, S1, S2 100-year outfall flows for the Year 2100. Computed peak 100-year flows in the Year 2100 were 413 cubic feet per second (cfs), 405 cfs, 315 cfs, 70 cfs, and 79 cfs, respectively. The CFD model was used to simulate discharges at a conservative low river water level of -0.6 ft Columbia River Datum CRD (4.7 ft NAVD88), which results in higher near-bed velocities than higher water levels. This water level was the lowest observed water level in the river from 2007 to 2023. Exit velocities were computed using Manning's equation and pipe system details documented in the Draft 50% RD CDTM (HGL, 2025b).

Figure 3-5 shows the maximum 100-year velocities predicted in the CFD model for City Outfalls M1, M2, M3, and S2, including climate change effects. Figure 3-5 (bottom left) also shows the

polynomial fit used to determine the estimated Year 2100 rainfall intensity; the polynomial shows an excellent fit to the University of Washington data, indicating a reliable estimate for design. Figure 3-6 shows the maximum bed shear stresses computed during the simulations, which have not changed significantly during the analysis except for climate change modifications. City Outfall S1 was not considered at this time pending updates to the RD at Lagoon Wharf, because resulting hydrodynamics or scour protection requirements for Outfall S-1 depend on slope modifications under the wharf and/or outfall discharge location. Peak velocities up to 30 ft per second were identified for the larger outfalls (M1, M2) and lower velocities were identified for the smaller outfalls (M3, S2). Due to the high velocities predicted in front of the outfalls, typical rock protection was deemed impractical. The 90% RD includes scour protection in the form of cast-in-place, fabric-formed concrete mattresses in relatively small, localized areas in front of City Outfalls M1, M2, M3, and S2. Scour protection at City Outfall S1 is not included in Pre-Final 90% RD.

3.5.2. Non-City Outfalls

Non-City outfalls are anticipated to be extended through any increased bank elevation areas, and discharge near top of bank. These outfalls are significantly smaller and require less robust armor protection.

3.6. RAINFALL RUNOFF

As compared to the conclusions outlined in Draft 50% RD, rainfall runoff is no longer a potential cap design criterion. Runoff from upland areas (above the Project Area boundary) will be controlled and directed to outfalls. All riverbanks will be stabilized, protected, and/or remediated. Wind-waves govern material stability on banks where rainfall runoff is active. However, rainfall-induced shear stresses were combined with the peak shear stresses Project Area-wide from other physical processes. Upland stormwater runoff onto riverbanks is precluded through stormwater controls.

3.7. MATERIAL STABILITY REQUIREMENTS

Material stability requirements were evaluated for in-water cap armor (Section 3.7.1), riverbank armoring required at steep slopes (Section 3.7.2), and for areas around City outfalls needing additional scouring considerations (Section 3.7.3).

3.7.1. In-Water Cap Armor

For in-water cap erosion protection (i.e., caps at the head of the basin and main basin outside of riverbanks), maximum bed shear stresses from all physical design considerations and related hydrodynamic processes listed above, except the City Outfalls, were used to identify stable grain sizes. A dynamic stability approach to EPL design (perhaps with larger thickness) may result in lower material sizes and overall costs, while remaining protective of the chemical isolation layer.

The Shields parameter was calculated using the maximum bed shear stresses from all considered hydrodynamic effects. The Shields parameter quantifies the ratio of the fluid force acting on a sediment particle to the gravitational force holding the particle in place. An empirical equation for initiation of motion (movement of particles along the bed) is given by Soulsby (1997), which

calculates the critical Shields parameter as a function of particle diameter. If the Shields parameter is greater than the critical Shields parameter, surface particle movement is likely to occur. The critical Shields parameter was also modified to account for bed slope effects and relative shear stress directions using a force balance equation (Soulsby, 1997). Stable median grain diameter was then calculated such that the shields parameter calculated using the design bed shear stresses did not exceed the modified critical Shields parameter.

Figure 3-7 shows the Pre-Final 90% RD combined bed shear stress map, including all hydrodynamic forces Project Area-wide, except rainfall runoff. The shear stress map has minor changes made relative to prior versions due to improvements in vessel traffic data sources and changes in outfall discharges noted in this CDTM. Figure 3-8 shows the median grain sizes of material suitable for in-water cap erosion protection if pure static stability of the surface materials is required, based on bed shear stress. The map of stable grain sizes excludes wave effects, outfall flows, and rainfall runoff, since bed shear stress is not used for the design of slope protection for these forces. Static stability of the surface materials in the EPL is not necessarily required to protect the CIL, if the EPL has sufficient thickness to accommodate a certain level of surface material dynamic equilibrium.

The Pre-Final 90% RD specifies material types based on both elevation (to comply with habitat requirements), estimated bed shear stresses, and significant additional conservatism to account for future uncertainties in future maritime operations in SIB. These erosion protection requirements are applicable to the EPL above the CIL. The habitat layer surface material is expected to periodically mobilize under propeller wash and other forces, but is not anticipated to lose substantial thickness due to spatial variability of the forces. It is anticipated that periodic maintenance of the habitat layer may be required in localized areas.

3.7.2. Bank Protection Armor

Riverbank armoring in the form of rock revetments is required in some areas due to steep slopes and relatively energetic wave conditions, as shown in Section 3.2. In most areas, the proposed armoring is intended to replace existing armoring after slope remediation. Van Der Meer (CIRIA, 2007 and Battjes et al., 2000) shallow water calculations were utilized to determine the minimum armor stone size requirements. The formulation considers parameters including significant wave height and peak wave period, slope, number of incident waves to be considered during a storm, and structure permeability. These parameters were developed for each facility in the SIB Project Area, and minimum armor stone median diameters were calculated.

Table 3-1 shows a summary of the assumed rock slope, wave parameters, and minimum stable median stone diameter used in the Pre-Final 90% RD. Two armor stone median diameters were selected: 12 inch (30 cm) and 8 inch (20 cm). The 12-inch median armor stone diameter was specified for areas nearest the main river (e.g., shipyard), and properties where wind-waves from the main river penetrate to the shoreline (e.g., U.S. Coast Guard). The 8-inch median armor stone diameter was prescribed in the interior of SIB in less energetic areas.

3.7.3. City Outfall Scour Protection

City Outfalls discharge at high velocity near the in-water cap, which has more mobile erosion protection materials (e.g., habitat mix) in shallow water. As noted above, due to high discharge velocities, cast-in-place fabric-formed concrete mattresses were designed for the 90% RD. Mattress design at each City Outfall was developed using modeling efforts discussed in Section 3.5.

The critical shear stress for initiation of motion for the habitat mix surrounding some of the mattresses (approximately less than 2.5-inch rounded gravel) was calculated to be 43 Pa, using Soulsby (1997). Using the spatial distribution of shear stresses in the model results at each City Outfall, mattress extents were designed to cover areas with shear stresses greater than 43 Pa. Mattress thicknesses were calculated using Hawkswood (2023), based generally on design velocity and mattress geometry information. To account for the relatively short time history of discharge used to predict 100-year discharge values, conservative values were used for mattress thickness design parameters such as the mattress surface undulation factor (I_Q) and the stability coefficient for concrete mattresses (C_F). The I_Q was assumed to be 1.15 which is the maximum value to be used for "low surface undulation" (Hawkswood, 2023). Mattresses with low surface undulation are preferred as they are subject to lower suction loads and distribute loading better (Hawkswood, 2023). The stability coefficient (CF) was assumed to be 0.19, which represents a high stability coefficient (Hawkswood, 2023). Both parameters selected resulted in a larger mattress thickness to ensure stability based on limited discharge data. PIANC (2015) also includes mattress stability formulations but recommends the use of Hawkswood-type formulations for design of in-situ (cast-in-place) concrete protection types.

While sufficient conservatism is present in the stable concrete mattress thicknesses noted here, practical design considerations for the mattresses have resulted in an increase in thickness for all mattresses to 24 inches. This allows the mattress to be installed on top of bedding stone, while the top surface remains flush with the top of the surrounding armor stone (or cap, in some areas). In addition, mattress extents were slightly increased in different dimensions for better inclusion into the slope design.

Table 3-2 shows a summary of the design velocities and computed minimum concrete mattress thicknesses at City Outfalls M1, M2, M3, and S2 (note: during 90% RD, all mattress thicknesses have been increased to 24 inch). City Outfall S1 was not evaluated in the mattress design because a mattress is not proposed (or required) under Lagoon Wharf.

3.7.4. Non-City Outfall Scour Protection

Local protection has been developed in the form of small, erosion-resistant drainage channels from each outfall discharge locations down the slope to the revetment areas. The drainage channels have been developed based on City specifications (City of Portland, 2025). Details can be found in the City of Portland Stormwater Management Manual, Appendix B, Section B.3.2. Rock specified for the drainage channels following City guidelines will be approximately 4 to 8-inch angular rock. The channel dimensions were specified according to City guidelines.

3.8. EROSION PROTECTION LAYER ASSIGNMENT

The two types of EPL in areas outside the revetment zone (Figure 1-1) consist of 2 ft (60 cm) of materials as specified in Section 35 37 10 (Engineered Caps, Volume III, Appendix S) and shown in Capping Drawings (Volume III, Appendix T). Cap Type 1 comprises 2 ft of habitat gravel on top of the CIL. Cap Type 2 consists of 18 inches of approximately 3-inch median diameter rock for erosion protection, and 6 inches of habitat layer (unamended coarse sand) on top of the rock for habitat improvement. Capping in revetment zones consists of a rock revetment (stone protection system) with 2 ft of armor stone (either 8-inch or 12-inch median diameter angular rock) placed over 1 ft of bedding stone (3-in median diameter angular rock). On slopes 3H:1V or flatter, less than 2-inch rounded gravel will also be placed on top of the revetment to improve habitat quality. Complete riverbank design specifications, including revegetation considerations and revetment details, are provided in the Drawings (Volume III, Appendix T) and RDTM (Volume I, Appendix D).

4.0 AREA-SPECIFIC CAP ALTERNATIVE ASSIGNMENT

Area-specific cap alternative assignment was completed using a cap assignment matrix that systematically evaluated the protective capability of 11 CIL alternatives (detailed in Section 2, Tables 2-3a and 2-3c) against CU area-specific sediment concentrations described in Section 1.1. The matrix analyzed each of the 27 COCs driving cap design in each RCU and CCU, then assigned the minimum protective alternative for each analyte within each CU, if that analyte exceeded CUL (otherwise, “No Cap Needed” was assigned). After evaluating all assigned alternatives, the matrix identified the most protective alternative for each CU to ensure containment of all analytes. The matrix incorporated additional design considerations into these assignments, as described in Section 4.1, before generating the final cap alternative assignments for each CU, described in Section 4.2.

4.1. CAP ALTERNATIVE ASSIGNMENT CONSIDERATIONS

Cap alternative assignment included the following special considerations:

- Riverbanks and sediment grid cells adjacent to riverbanks within revetment zone had Tektoseal alternatives assigned to them as the preferred remedial assignment (as compared to GAC amended sand), if Tektoseal is protective for all analytes. This consideration was driven by constructability consideration which determined that placement of Tektoseal is preferred to placement of loose GAC-amended sand on a steep slope.

- For CCUs outside of the revetment zone, 1 ft of amended sand was selected instead of 6 inches of amended sand due to constructability considerations, mainly due to tolerance needed for placement of a thin cap. As seen in Table 4-1 and on Figure 4-1, this applied to 20 CCUs.

- If cores didn’t have sufficient data to assign a protective alternative (e.g., due to dredging removing the analyte concentrations that would drive the design as seen in the Attachment A figures), the adjacent most protective alternative assigned was applied to that cell for

continuity and conservative capping approach. As seen in Table 4-1 and in Figure 4-1, this applied to five CCUs (CCU 93, CCU 95, CCU 103, CCU 104, and CCU 107).

4.2. FINAL CAP ALTERNATIVE ASSIGNMENTS

As seen in Figure 4-1 and Table 4-1, cap alternative assignments were determined for 107 CCUs and 30 RCUs. Two CCUs (CCU 5 and CCU 84) didn't need caps because their maximum sediment concentrations were below CULs. Out of 11 alternatives (described in Section 2.0), Cap Design Alternatives 1, 2, 3, 7, and 11 were selected for selected constructible concepts, alongside erosion protection layer assignments (Section 3.8). These alternatives were assigned to the minimum constructible cap designs as shown in Figure 4-2 and comprise:

- **Selected Constructible Alternative A:** 1 ft (30 cm) of unamended sand with overlying 2 ft (60 cm) Cap Type 1.
- **Selected Constructible Alternative B:** 1 foot (30 cm) of 5 percent GAC-amended sand with overlying 2 ft (60 cm) Cap Type 2.
- **Selected Constructible Alternative C:** 1 foot (30 cm) of 5 percent GAC-amended sand with overlying 2 ft (60 cm) Cap Type 1.
- **Selected Constructible Alternative D**: 6 inches of 5 percent GAC-amended sand with overlying 3 ft (90 cm) of stone protection system, including 2 ft (60 cm) of armor and 1 ft (30 cm) of bedding stone.
- **Selected Constructible Alternative E**: 1 foot (30 cm) of 5 percent GAC-amended sand with overlying 3 ft (90 cm) of stone protection system, including 2 ft (60cm) of armor and 1 ft (30 cm) of bedding stone.
- **Selected Constructible Alternative F**: 0.8 inches (2 cm) of Tektoseal-AC with overlying 3 ft (90 cm) of stone protection system in revetment zones, including 2 ft (60 cm) of armor and 1 ft (30 cm) of bedding stone.
- **Selected Constructible Alternative G**: 1.6 inches (4 cm) of Tektoseal-AC with overlying 3 ft (90 cm) of stone protection system in revetment zones, including 2 ft (60 cm) of armor and 1 ft (30 cm) of bedding stone

Minimum constructible protective alternative assignment includes:

- Selected Constructible Alternative A assigned to a single CCU – CCU 92.
- Selected Constructible Alternative B assigned to 71 CCUs. This includes 18 CCUs that were assigned 1 foot of 5 percent GAC-amended sand instead of 6 inches of 5 percent GAC-amended sand due to constructability considerations.
- Selected Constructible Alternative C assigned to 11 CCUs. This includes two CCUs that were assigned 1 foot of 5 percent GAC-amended sand instead of 6 inches of 5 percent GAC-amended sand due to constructability considerations.
- Selected Constructible Alternative D assigned to five CCUs – CCU 1 through CCU 3, CCU 8, and CCU 9.

- Selected Constructible Alternative E assigned to three CCUs – CCU 4, CCU 10, and CCU 62.
- Selected Constructible Alternative F assigned to seven CCUs and 11 RCUs.
- Selected Constructible Alternative G assigned to nine CCUs and 19 RCUs.

Drawings (Volume III, Appendix T) include additional details related to cap design:

- Transitions from cap design in CCU to RCUs
- Transitions from CCUs to DCUs (see Figure 4-1 and Table 1-1).
- Revegetation on top of EPL, if applicable.

Table 1-3a
Sediment Concentrations by Cap Certification Units
CDTM; Swan Island Basin Project Area, Portland, Oregon

Notes:
Blue values are maximum concentrations that were replaced with the Project area-wide 95th percentile value for capping evalaution.
#N/A = post-dredge analyte value not available for the certification unit
µg = microgram
95th %ile = Project area-wide 95th percentile concentrations for each analyte.
g = gram
kg = kilogram
pg = picogram
BEHP = BIS(2-ETHYLHEXYL) PHTHALATE
CCU = Cap Certification Unit
Chlordanes = Total Chlordane (Calculated U = 1/2)
CDTM = Cap Design Technical Memorandum
DDD = Total DDD (Calculated U = 1/2)
DDE = Total DDE (Calculated U = 1/2)
DDT = Total DDT (Calculated U = 1/2)
DDx = Total DDx (Calculated U = 1/2)
Diesel = Residual Range Organics (C25-C36)
HxCDF = 1,2,3,4,7,8-HEXACHLORODIBENZOFURAN
Lindane = GAMMA BHC (LINDANE)
N/A = Data not available for this analyte at this certification unit
PeCDD = 1,2,3,7,8-PENTACHLORODIBENZO-P-DIOXIN
TBT = Tributyltin
TCDD = 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN
TCDF = 2,3,4,7,8-PENTACHLORODIBENZOFURAN
TCDF = 2,3,7,8-TETRACHLORODIBENZOFURAN
Total cPAHs (BaP Eq) = Total cPAH/BaPEq TEQ (EPA 1993) (Calculated U = 1/2)
Total D/F (TCDD-Eq) = 2,3,7,8-TCDD TOXIC EQUIVALENT (TEQ), (ND = 0.5)
Total PAHs = Total PAH (Calculated U = 1/2)
Total PCBs = Total PCB Aroclors (Calculated U = 1/2)

Notes:

For purpose of evaluating Kd update based on Project Area-adjacent values, Kd values were used as reported in Draft 50% RD. Koc values were converted to Kd using Kd=Koc*foc and using site-average foc value of 0.0232627 (See Table 1-6).

SPDI Site Wide calculation reported for EPA FL-sites was excluded from the Project Area-Measured Average.

% = percent

K_D = adsorption-desorption linear partitioning coefficient

Koc = organic carbon normalized partition coefficient

L/kg = Liter per kilogram

N/A =Value not available

RPD = relative percent difference

SIB = Swan Island Basin Project Area

SPDI = Supplemental Pre-Design Investigation

Notes:

mg/kg = milligrams per kilogram

FD = Field Duplicate

J = estimated value

N = normal sample

TOC = total organic carbon

Table 2-1
CapSIM Model Input Parameters
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Parameter		Units	Value	Site-Specific	Notes
Underlying Sediment					
Thickness	h_{sed}	cm	30	N/A	Selected largest value in range of sediment thicknesses suggested by ITRC, 2023.
Porosity	f_{sed}		0.449	No	Table 3.2 Total Porosity values assuming an even mixture of fine and coarse sand (Yu et al.,1993) and the average clay, silt, and sand content in subsurface cores (D-8.90, E-9.02, and D-9.09) in the Head of Swan Island Lagoon FSDR Appendix I (PGG, 2019).
Bulk Density	r_{sed}	g/cm^3	1.28	No	Table 2.1 (Yu et al, 1993), and assuming the average clay, silt, and sand content in the subsurface cores (D-8.90, E-9.02, and D-9.09) in the Head of Swan Island Lagoon FSDR Appendix I (PGG, 2019).
Total Organic Carbon	f_{ocsed}	%	2.363	Yes	See Table 1-6 and Section 1.3.
Fraction Organic Carbon	f_{ocsed}		0.02363		
Particle Size		mm	0.06	No	CapSIM default
Permeability		cm^2	6.0E-08	No	Kozeny & Carman calculation completed within CapSIM
Sorption Isotherm			Linear: $K_{oc}f_{oc}$ or K_D	N/A	CapSIM default
Capping Sand					
Porosity	f_{sand}		0.32	No	Table 3.2 Effective Porosity for medium sand (Yu et al, 1993).
Bulk Density	r_{sand}	g/cm^3	1.6	No	Regularly cited bulk density for dry sand.
Total Organic Carbon	$f_{tocsand}$	%	0.1	Yes	Mode of regionally tested and assumed sand cap f_{oc} including the following sites: Former Portland Gas Manufacturing Site (Anchor QEA, 2020), Crawford Street BODR (GeoEngineers, 2022), Pacific Gas & Electric Pier 39 (Haley & Aldrich, 2020), Quendall Terminals Site FS (Aspect & Arcadis, 2013).
Fraction Organic Carbon	f_{ocsand}		0.001		
Particle Size		mm	1.2125	No	Table 3-1 median of United Soil Classification System range of medium sand (0.425-2.0mm) (USDA, 2012).
Permeability		cm^2	5.8E-06	No	Kozeny & Carman calculation completed within CapSIM
Sorption Isotherm			Linear: $K_{oc}f_{oc}$ or K_D	N/A	CapSIM default
Activated Carbon					
Porosity	f_{ac}		0.6	No	CapSIM default
Bulk Density	r_{ac}	g/cm^3	0.5126	No	Equivalent to approximate bulk density of Filtrasorb 400 (32 lbs/ft^3) received from Calgon Carbon in email communiction (Calgon Carbon, 2025)
Total Organic Carbon	f_{tocac}	%	100	No	CapSIM default
Fraction Organic Carbon	f_{ocac}		1.0		
Particle Size		mm	0.65	No	Median effective size of Filtrasorb 400 (CalgonCarbon, 2018)
Permeability		cm^2	3.2E-05	No	Kozeny & Carman calculation completed within CapSIM
Sorption Isotherm			Non-linear	N/A	CapSIM default. See Table 2-2 for specific sorption isotherm and values used.

Table 2-1
CapSIM Model Input Parameters
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Parameter		Units	Value	Site-Specific	Notes
Tektoseal (Textile)					
Porosity	f_{ac}		0.96	No	CapSIM default
Bulk Density	r_{ac}	g/cm^3	0.04	No	CapSIM default
Total Organic Carbon	f_{tocac}	%	0.0	No	CapSIM default
Fraction Organic Carbon	f_{ocac}		0.0		
Particle Size		mm	20	No	CapSIM default
Permeability		cm^2	1.0E-06	No	CapSIM default
Sorption Isotherm			Linear: K_D	N/A	CapSIM default. See Table 2-2 for specific sorption isotherm and values used.
Tektoseal-AC (Activated Carbon)					
Porosity	f_{ac}		0.6	No	Porosity of activated carbon layer in Tektoseal Active AC 3400 received from Huesker, Inc. in email communication (Huesker, 2024).
Bulk Density	r_{ac}	g/cm^3	0.37	No	Bulk density of activated carbon layer in Tektoseal Active AC 3400 received from Huesker, Inc. in email communication (Huesker, 2024).
Total Organic Carbon	f_{tocac}	%	100	No	CapSIM default
Fraction Organic Carbon	f_{ocac}		1.0		
Particle Size		mm	1.5	No	Median particle size of the range (0.5-2.5 mm; 8x30 mesh) of the activated carbon layer in Tektoseal Active AC 3400 received from Huesker, Inc. in email communication (Huesker, 2024).
Permeability		cm^2	1.0E-05	No	Minimum permeability of activated carbon layer in Tektoseal Active AC 3400 received from Huesker, Inc. in email communication (Huesker, 2024).
Sorption Isotherm			Non-linear	N/A	CapSIM default. See Table 2-2 for specific sorption isotherm and values used.
Tektoseal-HM (Heavy Metals)					
Porosity	f_{ac}		0.57	No	(TIG, 2023)
Bulk Density	r_{ac}	g/cm^3	0.43	No	(TIG, 2023)
Total Organic Carbon	f_{tocac}	%	0.0	No	(TIG, 2023)
Fraction Organic Carbon	f_{ocac}		0.0		
Particle Size		mm	1.25	No	(TIG, 2023)
Permeability		cm^2	1.07E-08	No	(TIG, 2023)
Sorption Isotherm			Linear: K_D	N/A	See Table 2-2 for specific sorption isotherm and values used.

Table 2-1
CapSIM Model Input Parameters
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Parameter		Units	Value	Site-Specific	Notes
Erosion Protection Layer (EPL)					
Thickness	h_{ep}	cm	60	N/A	EPL thickness is 2 ft (60 cm), see Figure 4-2.
Porosity	f_{ep}		0.3	No	Yu et al. (1993) Table 3.2 Total Porosity average of range for coarse gravel
Bulk Density	r_{ep}	g/cm^3	1.8	No	From Table 2 from Sakr et al. (2016)
Total Organic Carbon	f_{tocep}	%	0	No	Assumed 0% organic carbon for clean gravel to remove possibility for chemical adsorption in the erosion protection layer
Fraction Organic Carbon	f_{ocep}		0.0		
Particle Size		mm	152.4	Yes	The Project area-wide minimum median armor stone diameter (6 inch) specified in Table 3-1
Permeability		cm^2	0.071	No	Kozeny & Carman calculation completed within CapSIM
Sorption Isotherm			Linear: $K_{oc}f_{oc}$ or K_D	N/A	CapSIM default
Bedding Stone					
Thickness	h_{ep}	cm	30	N/A	The bedding stone thickness is 1 ft (30 cm), see Figure 4-2.
Porosity	f_{ep}		0.28	No	Yu et al. (1993) Table 3.2 Total Porosity arithmetic mean for coarse gravel
Bulk Density	r_{ep}	g/cm^3	1.8	No	From Table 2 from Sakr et al. (2016)
Total Organic Carbon	$f_{tocsand}$	%	0.00	No	Assumed 0% organic carbon for clean gravel to remove possibility for chemical adsorption in the erosion protection layer
Fraction Organic Carbon	f_{ocsand}		0.0		
Particle Size		mm	63.5	Yes	Median of the 2-3 inch diameter angular rock used for bedding stone
Permeability		cm^2	9.5E-03	No	Kozeny & Carman calculation completed within CapSIM
Sorption Isotherm			Linear: $K_{oc}f_{oc}$ or K_D	N/A	CapSIM default
Armor Stone					
Thickness	h_{ep}	cm	60	N/A	Armor stone thickness is 2 ft, see Figure 4-2.
Porosity	f_{ep}		0.3	No	Yu et al. (1993) Table 3.2 Total Porosity average of range for coarse gravel
Bulk Density	r_{ep}	g/cm^3	1.8	No	From Table 2 from Sakr et al. (2016)
Total Organic Carbon	$f_{tocsand}$	%	0.00	No	Assumed 0% organic carbon for clean gravel to remove possibility for chemical adsorption in the erosion protection layer
Fraction Organic Carbon	f_{ocsand}		0.0		
Particle Size		mm	254	Yes	Median of the 2-3 inch diameter angular rock used for armor stone
Permeability		cm^2	2.0E-01	No	Kozeny & Carman calculation completed within CapSIM
Sorption Isotherm			Linear: $K_{oc}f_{oc}$ or K_D	N/A	CapSIM default

Table 2-1
CapSIM Model Input Parameters
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Parameter		Units	Value	Site-Specific	Notes
General Input					
Darcy Velocity		cm/year	128	Yes	Steady flow upwelling assumed (sensitivity analysis completed previously showed no impact of diurnal oscillation period). The value for the main evaluation used was 128 cm/year, consistent with the maximum 50-hour average specific discharge recorded during the Porewater Upwelling Study and reported in Appendix B of the PDI ER (HGL, 2024).
Hyporheic Exchange			None	N/A	Assumed
Erosion			None	N/A	Assumed
Bioturbation		cm	20	Yes	Uniform bioturbation within modeled depth with particle size impact. Depth estimated is the high end of the estimated range reported in Portland Harbor RI/FS Appendix D (EPA, 2016)
Particle Biodiffusion Coefficient		cm^2/year	8.74	No	Selected average literature values (Reible 2014, Sections 2.3.2 and 2.3.3)
Pore Water Biodiffusion Coefficient		cm^2/year	173	No	
Maximum Consolidation Depth		cm	29.2	Yes	Upper bound consolidation values assuming 1 ft minimum dredge of existing material, 3 ft cap thickness, and no allowance for construction staging.
Time to 90% Consolidation		year	1.2	Yes	
Ionic Activity			None	N/A	Assumed
Deposition			None	N/A	Conservatively assumed no sediment deposition
Decay			None	N/A	Conservatively assumed no contaminant decay
Number of Grids per Layer			20	N/A	CapSIM guidance documents recommends using a uniform number of grid cells in each layer (Reible, 2022).
Time Step Size		year	0.1	N/A	CapSIM default
Hydrodynamic Dispersivity		%	10	N/A	CapSIM guidance documents recommend 10% of layer thickness (Reible, 2022)
Porewater DOC Concentration		mg/L	0.0	No	Assumed
Boundary Conditions					
Benthic Boundary Condition Type			Mass Transfer	N/A	CapSIM guidance documents recommendation for evaluating cap breakthrough (Reible, 2022)
Water Dissolved Organic Matter		mg/L	1.0	No	Assumed
Benthic Boundary Water DOC Concentration		µg/L	1.0E-25	No	Assumed value close to 0.
Mass Transfer Coefficient		cm/year	876	No	Equivalent to 0.1 cm/hr, which is one order of magnitude lower than the CapSIM default value (1.0 cm/hr) and falls within EPA recommendation of using a mass transfer coefficient less than 0.5 cm/hr.
Bottom Boundary Condition Type			Fixed Concentration	N/A	Conservatively assumed constant supply of contaminants
Bottom Concentration		µg/L	Variable	N/A	See Tables 1-3a and 1-3b for boundary concentrations for each modeled scenario

Table 2-1
CapSIM Model Input Parameters
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Notes:
% = percent
cm = centimeter
cm/hr = centimeter per hour
cm/year = centimeter per year
cm^2 = centimeter squared
cm^2/year = centimeter squared per year
g/cm^3 = grams per meter cubic
µg/L = micrograms per liter
mg/L = milligrams per liter
mm = millimeter
BODR = basis of design report
N/A = not applicable

Table 2-2
Chemical Properties and Partitioning Coefficients for Modeled COCs
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Notes:
cm = centimeter
cm^2 = centimeter squared
cm^2/year = centimeter squared per year
µg/L = micrograms per liter
K_{oc} = organic carbon-water partition coefficient
K_{doc} = dissolved organic carbon-water partition coefficient
K_F = Freundlich partition coefficient
B(a)P = benzo(a)pyrene
cPAHs = carcinogenic polycyclic aromatic hydrocarbons
Eq. = equivalents
PAHs = polycyclic aromatic hydrocarbons
PCBs = polychlorinated biphenyls
PeCDD = pentachlorodibenzo-p-dioxin
PeCDF = pentachlorodibenzofuran
TCDD = tetrachlorodibenzo-p-dioxin
TCDF = tetrachlorodibenzofuran
a. Model inputs for DDx, Total PAHs, and Total PCBs are based on the average values of the individual COCs. Total cPAHs is based on benzo(a)pyrene. Total Dioxins/Furans is based on 2,3,7,8-TCDD.
b. Diffisivities were sourced from: (New Mexico Environment Department, 2021) for 1-Methylnaphthalene, 2-Methylnaphthalene, Beta-chloronaphthalene, Phenanthrene; (Division of Spill Prevention and Response Contaminated Sites Program, 2018) for Acenaphthylene and Benzo(g,h,i)perylene; (EPA, 1996) for B(a)P, Fluorene, Naphthalene, DDD, DDE, DDT; (NJDEP, 2014) for BEHP, Chlordanes, Dieldrin, Lindane, Pentachlorophenol; (California Department of Toxic Substances Control, 2009) for Diesel; (Addeck et al., 2014) for HxCDF and TCDF; (GeoEnginers, 2022) for PeCDD; (Gilkinson, 1999) for PeCDF; (Addeck et al., 2012) for TCDD; (RAIS Toxicity Values and Physical Parameters Search, n.d.) for Tributyltin; (Center for Environmental & Human Toxicology, University of Florida, 2005) for Vanadium; and the CapSim defaults for all individual cPAHs and PCBs, Acenaphthene, Aldrin, Anthracene, Arsenic, Benzene, Benzo(e)pyrene, Cadmium, Chromium, Copper, Fluoranthene, Lead, Manganese, Mercury, Pyrene, Total PAHs, Total PCBs.
c. The sources for COC sorption to sediment and capping materials are detailed in Appendix C.
d. COC sorption parameters for the amendment material of the Tektoseal-HM product were obtained from TIG (2023).
e. Log Kdoc were sourced from: (The Louis Berger Group, 2014) and the Burkhard (2000) method for HxCDF, TCDF; (EPA, 2023) and the Burkhard method for BEHP; (The Louis Berger Group, 2014) and estimating method Kdoc = Kow/10 for PeCDF, TCDD; (Meador et al, 1995) and estimating method Kdoc = Kow/10 for 1-Methylnaphthalene, 2-Methylnaphthalene; (Mabey et al, 1982) for Beta-chloronaphthalene; (Burgess et al, 2012) for Dieldrin; (Fukushima et al, 2005) for Lindane, Pentachlorophenol, Tributyltin; (GeoEngineers, 2022) for PeCDD, Total PAHs, Total PCBs; CapSim reference documents for Acenaphthylene, Fluorene, Phenanthrene; and the CapSim Defaults for all Individual cPAHs and PCBs, Acenaphthene, Aldrin, Anthracene, Arsenic, Benzo(e)pyrene, Benzene, Cadmium, Chlordanes, Chromium, Copper, DDD, DDE, DDT, Fluoranthene, Lead, Manganese, Mercury, Pyrene, Naphthalene, Toluene, Xylenes, Zine. Data was unavailable for Diesel, and 0 was assumed.

Table 2-3a
Time-to-Breakthrough Summary Results of Sand and Amended Sand Cap Modeling, 95th Percentile
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Notes:
100+ = time-to-breakthrough exceeds 100 years
% = percent
BEHP = bis(2-ethylhexyl) phthalate
Chlordanes = Total Chlordane (Calculated U = 1/2)
COC = contaminant of concern
cPAHs = carcinogenic polycyclic aromatic hydrocarbons
DDD = dichlorodiphenyldichloroethane
DDE = dichlorodiphenyldichloroethylene
DDT = dichlorodiphenyltrichloroethane
DDx = DDD + DDE + DDT
Diesel = Residual Range Organics (C25-C36)
GAC = granular activated carbon
HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran
Lindane = Gamma BHC
PeCDD = pentachlorodibenzo-p-dioxin
PeCDF = pentachlorodibenzofuran
TCDD = tetrachlorodibenzo-p-dioxin
TCDF = tetrachlorodibenzofuran
Total Dioxins/Furans = 2,3,7,8-TCDD Equivalent
Total cPAHs = Benzo(a)pyrene Equivalent
GAC amendment percentage is by weight.
Time-to-breakthrough is defined as the time in years elapsed between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the relevant CUL at the CPP.
Cap performance point (CPP) is at the top surface of the chemical isolation layer, 30cm below cap-surface water interface.

Table 2-3b

Table 2-3b
Time-to-Breakthrough Summary Results of Sand and Amended Sand Cap Modeling, 95th Percentile
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Notes:

100+ = time-to-breakthrough exceeds 100 years

% = percent

BEHP = bis(2-ethylhexyl) phthalate

Chlordanes = Total Chlordane (Calculated U = 1/2)

COC = contaminant of concern

cPAHs = carcinogenic polycyclic aromatic hydrocarbons

DDD = dichlorodiphenyldichloroethane

DDE = dichlorodiphenyldichloroethylene

DDT = dichlorodiphenyltrichloroethane

DDx = DDD + DDE + DDT

Diesel = Residual Range Organics (C25-C36)

GAC = granular activated carbon

HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran

Lindane = Gamma BHC

PeCDD = pentachlorodibenzo-p-dioxin

PeCDF = pentachlorodibenzofuran

TCDD = tetrachlorodibenzo-p-dioxin

TCDF = tetrachlorodibenzofuran

Total Dioxins/Furans = 2,3,7,8-TCDD Equivalent

Total cPAHs = Benzo(a)pyrene Equivalent

GAC amendment percentage is by weight.

Time-to-breakthrough is defined as the time elapsed in years between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the relevant CUL at the CPP.

Cap performance point (CPP) is at the top surface of the chemical isolation layer, 30cm below cap-surface water interface.

Chromium (III), DDx, and PCBs have different Table 17 surface water (SW) and groundwater (GW) CULs. For these COCs, the applicable criteria is notated alongside the time-to-exceedance, with the lower CUL listed first if both are exceeded.

Table 2-3d
Time-to-Exceedance of Groundwater and Surface Water CUL, 95th Percentile
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Notes:

RPDs are calculated based on the 100-year porewater concentrations. RPDs in red indicate that the sensitivity concentration is higher than the base case concentration. RPDs in green indicate that the sensitivity concentration is lower than the base case concentration. A dash (-) is used for a COC when both the base case and sensitivity scenarios have 100-year porewater concentrations of 0 µg/L.

100+ = time-to-breakthrough exceeds 100 years

% = percent

µg/kg = micrograms per kilogram

µg/L = micrograms per liter

BEHP = bis(2-ethylhexyl) phthalate

Chlordanes = Total Chlordane (Calculated U = 1/2)

cm = centimeter

COC = contaminant of concern

cPAHs = carcinogenic polycyclic aromatic hydrocarbons

C_{PW} = porewater concentration

C_{Sed} = sediment concentration

CPP = Cap Performance Point -> top of chemical isolation layer.

DDD = dichlorodiphenyldichloroethane

DDE = dichlorodiphenyldichloroethylene

DDT = dichlorodiphenyltrichloroethane

DDx = DDD + DDE + DDT

Diesel = Residual Range Organics (C25-C36)

GAC = granular activated carbon, amendment percentage by weight

HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran

Lindane = Gamma BHC

PeCDD = pentachlorodibenzo-p-dioxin

PeCDF = pentachlorodibenzofuran

RPD = Relative Percent Difference

TCDD = tetrachlorodibenzo-p-dioxin

TCDF = tetrachlorodibenzofuran

Total cPAHs = Benzo(a)pyrene Equivalent

Total Dioxins/Furans = 2,3,7,8-TCDD Equivalent

TTB = Time-to-breakthrough is defined as the time in years elapsed between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the relevant CUL at the CPP.

Table 2-5
Cap Modeling Input Parameters Sensitivity Analyses, Chemical Isolation Layer Thickness
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Notes:
100+ = time-to-breakthrough exceeds 100 years
% = percent
µg/kg = micrograms per kilogram
µg/L = micrograms per liter
BEHP = bis(2-ethylhexyl) phthalate
Chlordanes = Total Chlordane (Calculated U = 1/2)
cm = centimeter
COC = contaminant of concern
cPAHs = carcinogenic polycyclic aromatic hydrocarbons
C_{PW} = porewater concentration
C_{Sed} = sediment concentration
CPP = Cap Performance Point -> top of chemical isolation layer.
DDD = dichlorodiphenyldichloroethane
DDE = dichlorodiphenyldichloroethylene
DDT = dichlorodiphenyltrichloroethane
DDx = DDD + DDE + DDT
Diesel = Residual Range Organics (C25-C36)
GAC = granular activated carbon, amendment percentage by weight
HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran
Lindane = Gamma BHC
PeCDD = pentachlorodibenzo-p-dioxin
PeCDF = pentachlorodibenzofuran
RPD = Relative Percent Difference
TCDD = tetrachlorodibenzo-p-dioxin
TCDF = tetrachlorodibenzofuran
Total cPAHs = Benzo(a)pyrene Equivalent
Total Dioxins/Furans = 2,3,7,8-TCDD Equivalent
TTB = Time-to-breakthrough is defined as the time elapsed between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the relevant CUL at the CPP.

Table 2-6
Cap Modeling Input Parameters Sensitivity Analyses, Freundlich Sorption Parameters
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Notes:

RPDs are calculated based on the 100-year porewater concentrations. RPDs in red indicate that the sensitivity concentration is higher than the base case concentration. RPDs in green indicate that the sensitivity concentration is lower than the base case concentration. A dash (-) is used for a COC when both the base case and sensitivity scenarios have 100-year porewater concentrations of 0 µg/L.

100+ = time-to-breakthrough exceeds 100 years

% = percent

µg/kg = micrograms per kilogram

µg/L = micrograms per liter

BEHP = bis(2-ethylhexyl) phthalate

Chlordanes = Total Chlordane (Calculated U = 1/2)

cm = centimeter

COC = contaminant of concern

cPAHs = carcinogenic polycyclic aromatic hydrocarbons

C_{PW} = porewater concentration

C_{Sed} = sediment concentration

CPP = Cap Performance Point -> top of chemical isolation layer.

DDD = dichlorodiphenyldichloroethane

DDE = dichlorodiphenyldichloroethylene

DDT = dichlorodiphenyltrichloroethane

DDx = DDD + DDE + DDT

Diesel = Residual Range Organics (C25-C36)

GAC = granular activated carbon, amendment percentage by weight

HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran

Lindane = Gamma BHC

PeCDD = pentachlorodibenzo-p-dioxin

PeCDF = pentachlorodibenzofuran

RPD = Relative Percent Difference

TCDD = tetrachlorodibenzo-p-dioxin

TCDF = tetrachlorodibenzofuran

Total cPAHs = Benzo(a)pyrene Equivalent

Total Dioxins/Furans = 2,3,7,8-TCDD Equivalent

TTB = Time-to-breakthrough is defined as the time elapsed between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the relevant CUL at the CPP.

Table 2-8
Cap Modeling Input Parameters Sensitivity Analyses, Linear Sorption to Sand
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Notes:
RPDs are calculated based on the 100-year porewater concentrations. RPDs in red indicate that the sensitivity concentration is higher than the base case concentration. RPDs in green indicate that the sensitivity concentration is lower than the base case concentration. A dash (-) is used for a COC when both the base case and sensitivity scenarios have 100-year porewater concentrations of 0 µg/L.

100+ = time-to-breakthrough exceeds 100 years

% = percent

µg/kg = micrograms per kilogram

µg/L = micrograms per liter

BEHP = bis(2-ethylhexyl) phthalate

Chlordanes = Total Chlordane (Calculated U = 1/2)

cm = centimeter

COC = contaminant of concern

cPAHs = carcinogenic polycyclic aromatic hydrocarbons

C_{PW} = porewater concentration

C_{Sed} = sediment concentration

CPP = Cap Performance Point -> top of chemical isolation layer.

DDD = dichlorodiphenyldichloroethane

DDE = dichlorodiphenyldichloroethylene

DDT = dichlorodiphenyltrichloroethane

DDx = DDD + DDE + DDT

Diesel = Residual Range Organics (C25-C36)

GAC = granular activated carbon, amendment percentage by weight

HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran

Lindane = Gamma BHC

PeCDD = pentachlorodibenzo-p-dioxin

PeCDF = pentachlorodibenzofuran

RPD = Relative Percent Difference

TCDD = tetrachlorodibenzo-p-dioxin

TCDF = tetrachlorodibenzofuran

Total cPAHs = Benzo(a)pyrene Equivalent

Total Dioxins/Furans = 2,3,7,8-TCDD Equivalent

TTB = Time-to-breakthrough is defined as the time elapsed between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the relevant CUL at the CPP.

Table 2-9
Cap Modeling Input Parameters Sensitivity Analyses, Linear Sorption to Sediment
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Notes:

RPDs are calculated based on the 100-year porewater concentrations. RPDs in red indicate that the sensitivity concentration is higher than the base case concentration. RPDs in green indicate that the sensitivity concentration is lower than the base case concentration. A dash (-) is used for a COC when both the base case and sensitivity scenarios have 100-year porewater concentrations of 0 µg/L.

100+ = time-to-breakthrough exceeds 100 years

% = percent

µg/kg = micrograms per kilogram

µg/L = micrograms per liter

BEHP = bis(2-ethylhexyl) phthalate

Chlordanes = Total Chlordane (Calculated U = 1/2)

cm = centimeter

COC = contaminant of concern

cPAHs = carcinogenic polycyclic aromatic hydrocarbons

C_{PW} = porewater concentration

C_{Sed} = sediment concentration

CPP = Cap Performance Point -> top of chemical isolation layer.

DDD = dichlorodiphenyldichloroethane

DDE = dichlorodiphenyldichloroethylene

DDT = dichlorodiphenyltrichloroethane

DDx = DDD + DDE + DDT

Diesel = Residual Range Organics (C25-C36)

GAC = granular activated carbon, amendment percentage by weight

HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran

Lindane = Gamma BHC

PeCDD = pentachlorodibenzo-p-dioxin

PeCDF = pentachlorodibenzofuran

RPD = Relative Percent Difference

TCDD = tetrachlorodibenzo-p-dioxin

TCDF = tetrachlorodibenzofuran

Total cPAHs = Benzo(a)pyrene Equivalent

Total Dioxins/Furans = 2,3,7,8-TCDD Equivalent

TTB = Time-to-breakthrough is defined as the time elapsed between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the relevant CUL at the CPP.

Table 2-10
Sensitivity Analyses, Linear Sorption to EPL
CDTM; Swan Island Basin Project Area, Portland, Oregon

Notes:

RPDs are calculated based on the 100-year porewater concentrations. RPDs in red indicate that the sensitivity concentration is higher than the base case concentration. RPDs in green indicate that the sensitivity concentration is lower than the base case concentration. A dash (-) is used for a COC when both the base case and sensitivity scenarios have 100-year porewater concentrations of 0 µg/L.

100+ = time-to-breakthrough exceeds 100 years

% = percent

µg/kg = micrograms per kilogram

µg/L = micrograms per liter

BEHP = bis(2-ethylhexyl) phthalate

Chlordanes = Total Chlordane (Calculated U = 1/2)

cm = centimeter

COC = contaminant of concern

cPAHs = carcinogenic polycyclic aromatic hydrocarbons

C_{PW} = porewater concentration

C_{Sed} = sediment concentration

CPP = Cap Performance Point -> top of chemical isolation layer.

DDD = dichlorodiphenyldichloroethane

DDE = dichlorodiphenyldichloroethylene

DDT = dichlorodiphenyltrichloroethane

DDx = DDD + DDE + DDT

Diesel = Residual Range Organics (C25-C36)

GAC = granular activated carbon, amendment percentage by weight

HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran

Lindane = Gamma BHC

PeCDD = pentachlorodibenzo-p-dioxin

PeCDF = pentachlorodibenzofuran

RPD = Relative Percent Difference

TCDD = tetrachlorodibenzo-p-dioxin

TCDF = tetrachlorodibenzofuran

Total cPAHs = Benzo(a)pyrene Equivalent

Total Dioxins/Furans = 2,3,7,8-TCDD Equivalent

TTB = Time-to-breakthrough is defined as the time elapsed between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the relevant CUL at the CPP.

Notes:

concentration. RPDs in green indicate that the sensitivity concentration is lower than the base case concentration. A dash (-) is used for a COC when both the base case and sensitivity scenarios have 100-year porewater concentrations of 0 µg/L.

100+ = time-to-breakthrough exceeds 100 years

% = percent

µg/kg = micrograms per kilogram

µg/L = micrograms per liter

BEHP = bis(2-ethylhexyl) phthalate

Chlordanes = Total Chlordane (Calculated U = 1/2)

cm = centimeter

COC = contaminant of concern

cPAHs = carcinogenic polycyclic aromatic hydrocarbons

C_{PW} = porewater concentration

C_{Sed} = sediment concentration

CPP = Cap Performance Point -> top of chemical isolation layer.

DDD = dichlorodiphenyldichloroethane

DDE = dichlorodiphenyldichloroethylene

DDT = dichlorodiphenyltrichloroethane

DDx = DDD + DDE + DDT

Diesel = Residual Range Organics (C25-C36)

GAC = granular activated carbon, amendment percentage by weight

HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran

Lindane = Gamma BHC

PeCDD = pentachlorodibenzo-p-dioxin

PeCDF = pentachlorodibenzofuran

RPD = Relative Percent Difference

TCDD = tetrachlorodibenzo-p-dioxin

TCDF = tetrachlorodibenzofuran

Total cPAHs = Benzo(a)pyrene Equivalent

Total Dioxins/Furans = 2,3,7,8-TCDD Equivalent

TTB = Time-to-breakthrough is defined as the time elapsed between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the relevant CUL at the CPP.

Table 2-12
Sensitivity Analyses, Flux Matching Bottom Boundary Condition
CDTM; Swan Island Basin Project Area, Portland, Oregon

Notes:
RPDs are calculated based on the 100-year porewater concentrations. RPDs in red indicate that the sensitivity concentration is higher than the base case concentration. RPDs in green indicate that the sensitivity concentration is lower than the base case concentration. A dash (-) is used for a COC when both the base case and

100+ = time-to-breakthrough exceeds 100 years

% = percent

µg/kg = micrograms per kilogram

µg/L = micrograms per liter

BEHP = bis(2-ethylhexyl) phthalate

Chlordanes = Total Chlordane (Calculated U = 1/2)

cm = centimeter

COC = contaminant of concern

cPAHs = carcinogenic polycyclic aromatic hydrocarbons

C_{PW} = porewater concentration

C_{Sed} = sediment concentration

CPP = Cap Performance Point -> top of chemical isolation layer.

DDD = dichlorodiphenyldichloroethane

DDE = dichlorodiphenyldichloroethylene

DDT = dichlorodiphenyltrichloroethane

DDx = DDD + DDE + DDT

Diesel = Residual Range Organics (C25-C36)

GAC = granular activated carbon, amendment percentage by weight

HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran

Lindane = Gamma BHC

PeCDD = pentachlorodibenzo-p-dioxin

PeCDF = pentachlorodibenzofuran

RPD = Relative Percent Difference

TCDD = tetrachlorodibenzo-p-dioxin

TCDF = tetrachlorodibenzofuran

Total cPAHs = Benzo(a)pyrene Equivalent

Total Dioxins/Furans = 2,3,7,8-TCDD Equivalent

TTB = Time-to-breakthrough is defined as the time elapsed between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the relevant CUL at the CPP.

Table 2-13
Sensitivity Analyses, Cap Consolidation
CDTM; Swan Island Basin Project Area, Portland, Oregon

Notes:

RPDs are calculated based on the 100-year porewater concentrations. RPDs in red indicate that the sensitivity concentration is higher than the base case concentration. RPDs in green indicate that the sensitivity concentration is lower than the base case concentration. A dash (-) is used for a COC when both the base case and sensitivity scenarios have 100-year porewater concentrations of 0 µg/L.

100+ = time-to-breakthrough exceeds 100 years

% = percent

µg/kg = micrograms per kilogram

µg/L = micrograms per liter

BEHP = bis(2-ethylhexyl) phthalate

Chlordanes = Total Chlordane (Calculated U = 1/2)

cm = centimeter

COC = contaminant of concern

cPAHs = carcinogenic polycyclic aromatic hydrocarbons

C_{PW} = porewater concentration

C_{Sed} = sediment concentration

CPP = Cap Performance Point -> top of chemical isolation layer.

DDD = dichlorodiphenyldichloroethane

DDE = dichlorodiphenyldichloroethylene

DDT = dichlorodiphenyltrichloroethane

DDx = DDD + DDE + DDT

Diesel = Residual Range Organics (C25-C36)

GAC = granular activated carbon, amendment percentage by weight

HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran

Lindane = Gamma BHC

PeCDD = pentachlorodibenzo-p-dioxin

PeCDF = pentachlorodibenzofuran

RPD = Relative Percent Difference

TCDD = tetrachlorodibenzo-p-dioxin

TCDF = tetrachlorodibenzofuran

Total cPAHs = Benzo(a)pyrene Equivalent

Total Dioxins/Furans = 2,3,7,8-TCDD Equivalent

TTB = Time-to-breakthrough is defined as the time elapsed between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the relevant CUL at the CPP.

Table 2-14
Cap Modeling Input Parameters Sensitivity Analyses, Sand and GAC Settling Separation
Cap Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Notes:

RPDs are calculated based on the 100-year porewater concentrations. RPDs in red indicate that the sensitivity concentration is higher than the base case concentration. RPDs in green indicate that the sensitivity concentration is lower than the base case concentration. A dash (-) is used for a COC when both the base case and sensitivity scenarios have 100-year porewater concentrations of 0 µg/L.

100+ = time-to-breakthrough exceeds 100 years

% = percent

µg/kg = micrograms per kilogram

µg/L = micrograms per liter

BEHP = bis(2-ethylhexyl) phthalate

Chlordanes = Total Chlordane (Calculated U = 1/2)

cm = centimeter

COC = contaminant of concern

cPAHs = carcinogenic polycyclic aromatic hydrocarbons

C_{PW} = porewater concentration

C_{Sed} = sediment concentration

CPP = Cap Performance Point -> top of chemical isolation layer.

DDD = dichlorodiphenyldichloroethane

DDE = dichlorodiphenyldichloroethylene

DDT = dichlorodiphenyltrichloroethane

DDx = DDD + DDE + DDT

Diesel = Residual Range Organics (C25-C36)

GAC = granular activated carbon, amendment percentage by weight

HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran

Lindane = Gamma BHC

PeCDD = pentachlorodibenzo-p-dioxin

PeCDF = pentachlorodibenzofuran

RPD = Relative Percent Difference

TCDD = tetrachlorodibenzo-p-dioxin

TCDF = tetrachlorodibenzofuran

Total cPAHs = Benzo(a)pyrene Equivalent

Total Dioxins/Furans = 2,3,7,8-TCDD Equivalent

TTB = Time-to-breakthrough is defined as the time elapsed between cap installation and the first occurrence of a COC porewater concentration equaling or surpassing the relevant CUL at the CPP.

Notes:
EPL in Selected Alternatives A and C consists of <2.5-in rounded gravel.
EPL in Selected Alternative B consists of:
6-in unamended coarse sand
18-in approximately 3-in median diameter angular rock.
Selected Constructible Alternatives D through G consist of:
Armor stone comprises 2-ft of 8-in or 12-in diameter angular rock.
Bedding stone comprises 1-ft of 3-in median diameter angular rock.
Selected Constructible Alternatives D and E contain 5% GAC Amended Sand CIL placed within geocell grids.
Selected Constructible Alternative F contains one layer of Tektoseal-AC reactive core mat.
Selected Constructible Alternative G contains two layers of Tektoseal-AC reactive core mat.
