**PRE-DESIGN INVESTIGATION WORK PLAN  
SWAN ISLAND BASIN PROJECT AREA  
PORTLAND HARBOR SUPERFUND SITE  
PORTLAND, MULTNOMAH COUNTY, OREGON**

## **1.0 INTRODUCTION**

This Pre-Design Investigation (PDI) Work Plan proposes an approach to collecting additional data, conducting surveys, and performing analysis necessary to develop the Remedial Design (RD) for the Swan Island Basin (SIB) Project Area within the Portland Harbor Superfund Site (PHSS). Upon U.S. Environmental Protection Agency (EPA) approval, this plan will guide a focused data collection and analysis effort to supplement existing data and analysis and provide the technical basis for developing the RD to remediate contaminated sediments and riverbanks within the SIB.

On December 1, 2000, PHSS was listed on the National Priorities List due to concerns about contamination in the riverbed sediments and the potential risks to human health and the environment. The most widespread contaminants found at PHSS include polychlorinated biphenyls (PCBs), polycyclic aromatic hydrocarbons (PAHs), and dioxins/furans. The vicinity and boundaries of the SIB Project Area are shown on Figure 1-1.

In January 2017, EPA issued a Record of Decision (ROD) that presents the selected remedy for the in-river portion of PHSS contamination. The selected remedy was chosen in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act, and to the extent practicable, the National Contingency Plan.

EPA published an Explanation of Significant Differences (ESD) (EPA, 2019a) after completion of a sitewide PDI (AECOM and Geosyntec, 2019). The ESD identified changes to the selected remedy and the reasons for such changes. The changes did not fundamentally alter the remedy. The ESD documented changes to the sediment cleanup levels (CULs) and shellfish target tissue level for carcinogenic PAHs and updated the Remedial Action Level (RAL) for total PAHs for areas of PHSS outside of the federal navigation channel. These updates were incorporated with other errata to update ROD Table 17 in Errata #2 (EPA, 2020). These changes have minor implications for RD within the SIB Project Area by potentially affecting the Sediment Management Area (SMA) boundaries.

On January 20, 2021, certain Parties<sup>1</sup> and EPA voluntarily entered into an Administrative Settlement Agreement and Order on Consent (ASAOC) (EPA, 2021a), to perform 100% RD work within the PHSS SIB Project Area. This PDI Work Plan along with the source control Sufficiency Assessment Report (SAR) provide an early foundation for the development of the RD.

---

<sup>1</sup> Parties to the Administrative Settlement Agreement and Order on Consent (ASAOC) are EPA and Daimler Trucks North America LLC, Vigor Industrial LLC, Cascade General, Inc., and Shipyard Commerce Center LLC (collectively, Respondent(s)); Maritime Administration, U.S. Coast Guard, U.S. General Services Administration, Bonneville Power Administration, and U.S. Department of Defense (collectively, Settling Federal Agencies); and the state of Oregon, acting by and through the Department of State Lands, the city of Portland, and the Port of Portland (collectively, Settling Public Entities).

## 1.1 PRE-DESIGN INVESTIGATION PURPOSE AND OBJECTIVES

The RD drives the data, survey, and analysis needs. The purpose of this PDI Work Plan is to:

- Determine what data and analysis are necessary to inform the RD;
- Identify and evaluate relevant, applicable, and existing data and analysis;
- Identify data gaps; and
- Propose an approach to collect the data and complete the analyses required to address those data gaps and design the remedy.

At this early phase, planning the PDI requires the design team to begin with a conceptual RD based on the remedial technology assignments for the selected remedy published in Appendix I of the PHSS ROD (EPA, 2017a) as illustrated on Figure 1-2. The preliminary design concepts provide an early basis to identify the specific data, surveys, and analysis needed to develop that design.

In addition to aligning with the specifications and requirements of the ROD, this PDI Work Plan must be developed according to the principles and recommended sampling techniques described in the *Remedial Design Guidelines and Considerations* document (EPA, 2021b). The PDI must provide the information necessary to select remedial technologies identified in the ROD as potentially applicable within the SIB Project Area. It also must include the information and analysis necessary to demonstrate that the remedy will be robust, sustainable, and effective in the context of the SIB including natural processes and human activities including vessel traffic, waterway maintenance, and activities on the shoreline and adjacent uplands. The elements of the RD concept and approach determine the data and analysis that is necessary. This work plan identifies and qualifies applicable existing data and analysis that may be reliably used to inform and support the design development. Data and analysis gaps are identified by comparing the applicable existing data and analysis to the list of data and analysis needs determined by the conceptual design. This PDI Work Plan identifies the scope of proposed data collection and analysis to fill those data gaps and the proposed approach for each component of the investigation.

The ASAOC (EPA, 2021a) specifically identifies three applications of the PDI results that support the development of the RD. Those specific applications are:

1. Refinement of SMAs.
2. Refinement of the conceptual site model (CSM).
3. Application of the technology application decision tree (Figure 1-3).

Each of these required applications aligns with and must be fulfilled by the approach presented in this PDI Work Plan.

As part of developing this PDI Work Plan, the RD team used available sediment characterization data collected since ROD publication in 2017 to prepare a preliminary refinement of the SIB SMA boundaries presented in the ROD. This exercise was an essential step in evaluating the data gaps and developing the proposed data collection plan for characterizing the spatial and vertical extent of contaminants of concern (COCs) within the SIB Project Area. That refinement is presented

within this PDI Work Plan. The same SMA boundary refinement exercise will be performed after completion of the PDI per this work plan using the new sediment characterization data collected in accordance with a Field Sampling Plan (FSP) (Appendix A) designed specifically for this purpose.

The CSM presented in ROD Figures 3, 4, and 5 applies to the entire PHSS. The CSM fulfills an essential purpose focused on identifying and describing, at a conceptual level, the critical elements of the site that are relevant to COC sources, release mechanisms, transport and exposure pathways, and ecological and human receptors. The CSM portrays these elements and how they relate and interact with one another in the context of the site considering physical, chemical, and ecological processes as well as human activities.

The SIB Project Area is physically distinct from the main river because most of the project area falls within a backwatered slip that is not subject to the higher flow velocities and resulting forces that transport sediments and COCs. These flows often substantially modify the physical configuration of the riverbed and riverbanks. The SIB Project Area is physically more stable in comparison to the main river. Refinements to the CSM as it specifically applies to the SIB Project Area are necessary to ensure that the remedy will be effective and sustainable in the context of the SIB and not subject to future recontamination. Section 2.2 of this PDI Work Plan presents initial refinements to the CSM specific to the SIB Project Area. Multiple data collection efforts and studies proposed for the PDI will provide the necessary information and analysis to further refine the CSM and provide a quantitative analytical basis for applying the CSM to developing and evaluating the RD in the applicable context. EPA's 7-step data quality objective process for each media will be utilized, as appropriate, throughout these efforts (EPA, 2006).

This PDI Work Plan will guide the collection of additional data and analysis necessary to apply the technology application decision tree to determine the location and extent of each remedial technology within the SIB Project Area. Figure 1-2 shows the delineated areas within the SIB Project Area for application of various remedial technologies (e.g., dredging, capping, monitored natural recovery [MNR], enhanced natural recovery [ENR], etc.). Figure 1-2 was generated by applying the decision tree using existing available data at the time the ROD was published in 2017. New data and analysis have become available since then, and this PDI Work Plan will guide additional data collection and analysis needed to fully inform the RD. The new data used in accordance with the decision tree will result in refinements to the technology applications with the SIB Project Area. Specific information needed to inform the use of the decision tree includes but is not limited to:

- Bathymetry and bank topography,
- Sediment chemistry (e.g., horizontal and vertical extent of COCs in sediments),
- Geotechnical characteristics of the riverbanks and sediments,
- Groundwater upwelling through sediments,
- Porewater chemistry,

- Navigation zones subject to maintenance dredging along with specified depth requirements, and
- Location and condition of shoreline and in-water structures.

This PDI Work Plan will guide new data collection and analysis that will include substantial updates to each of these information requirements necessary to apply the decision tree.

The overarching objective of this PDI Work Plan focuses on compiling a complete body of data and analysis to fully inform the development and evaluation of a RD for a sustainable and effective remedy for the SIB Project Area. Within that guiding objective, other specific objectives are used to guide the planning and implementation of the PDI to ensure this primary goal is met. Those objectives are listed below.

1. Define the specific data and analysis needs required to fully inform the design development and evaluation based on a conceptual design approach and strategy consistent with the ROD.
2. Ensure that the data and analysis needs are sufficient to support the three applications specifically required in the ASAOC for SMA refinement, CSM refinement, and effective use of the technology application decision tree (Figure 1-3).
3. Compile and evaluate existing available data and analysis relevant to the defined data and analysis needs as determined by the design and required applications.
4. Identify data gaps by comparing what is needed to what is available.
5. Develop a work plan to guide the collection of new data and the completion of new analyses to address the data gaps.

## **1.2 SWAN ISLAND BASIN PROJECT AREA DESCRIPTION**

The SIB Project Area is the active cleanup area between approximately River Mile (RM) 8.1 and RM 9.2 on the northeast side of the Willamette River (Figure 1-2). The SIB Project Area is approximately 1.1 miles in length, 117 acres in size, and includes riverbanks from top of the bank to the river.

The upland areas surrounding the SIB Project Area include approximately 588 acres of mostly impervious area with primarily light industrial uses (Figure 1-4). The SIB Project Area receives discharges from city of Portland outfall basins M-1, M-2, M-3, S-1, and S-2; six Port of Portland outfall basins; and multiple private outfalls at shoreline properties.

Section 2.0 includes a more detailed description of the project area, site conditions, and background. Additional information on the in-water and upland site characteristics in the SIB Project Area is included in the June 2021 SAR (Hydrogeologic, Inc. [HGL], 2021).

## **1.3 CONCEPTUAL REMEDIAL DESIGN ELEMENTS**

The application of the remediation technology process will demonstrate compliance with the EPA ROD technology application decision tree and the design requirements found in ROD Section

14.2.9. The application of the specific Remedial Actions (RAs) of dredging and capping will be based on the locations of RAL and principal threat waste (PTW) exceedances relative to river regions. The selected remedy identified in the ROD for the SIB Project Area designates approximately 117 acres for active remediation and approximately 6 acres of MNR technology (Figure 1-2). The final combination of active remedial technologies and MNR technology, and the sediment volumes and acreages associated with each remedial technology will be determined during the RD in coordination with EPA. Each remedial technology corresponds to an element of the RD. The following sections describe each RD element in the context of the SIB Project Area and identify the types of data and analysis necessary to support development and evaluation of the design. Section 3.0 summarizes existing applicable data and analysis and identifies data gaps based on what is needed to design the remedy. Section 4.0 proposes data collection and engineering studies that will address those data gaps. Each proposed data collection effort or study will be applied to one or more elements of the RD, and the linkages are mapped in the following discussions for each remedial technology. Information about future land uses is a necessary component when collecting data for the evaluation of the application of each technology.

### **1.3.1 Sediment Dredging via Future Maintenance Dredging in the Navigation Channel**

Sediment dredging via future maintenance dredging is proposed for the western (downstream) portion of the interior lagoon of the SIB Project Area. This remedial technology considers the future navigation depth requirement and specifies either dredging or dredging combined with capping to accommodate that future navigation depth and ensure sufficient depth to accommodate post-remedial maintenance dredging. The U.S. Army Corps of Engineers (USACE) designates and maintains the -50' Federal Navigation Channel and the channel does not extend into the SIB (Figure 1-1). However, it is acknowledged that the western portion of SIB is subject to coordination with both USACE and EPA to ensure that the slopes and depths are suitably compatible. The entirety of the SIB Project Area is located outside the Federal Navigation Channel and is therefore not subject to the specified future maintenance dredging depths associated with it. Navigation depth requirements within the SIB Project Area represent a critical data gap that will be addressed as part of the proposed PDI. Note that the western portion of the site adjacent to the navigation channel is anticipated to be remediated using ENR, so the remedy is unlikely to result in significant changes in slope or depth in this part of the project area.

Designing and evaluating this element of the RD will require the following data and analysis:

- Current and future navigational use of the waterway and associated depth requirements,
- Bathymetry,
- Sediment characterization of vertical and horizontal distribution of COCs,
- Condition assessment of adjacent shoreline structures,
- Geotechnical analysis of adjacent submerged slopes and bank slopes,
- Distribution of debris and utilities within and adjacent to the dredge area, and
- Hydrodynamics and sediment dynamics analysis.

### **1.3.2 Sediment Dredging**

The ROD specifies sediment dredging outside the future maintenance dredging zone for only a small portion of the SIB Project Area. The data needs for sediment dredging are the same as those listed for dredging via future maintenance dredging except for navigation depth requirements.

### **1.3.3 Sediment Dredging with Sediment Capping**

The ROD specifies sediment dredging with sediment capping together for limited portions of the SIB Project Area near the head of the lagoon and along the Mocks Bottom shoreline near the northeast end of the project area. Dredging with capping is applied where surface concentrations are too high for ENR to be protective and where contamination extends to a depth greater than what could be feasibly removed (for example, as limited by adjacent slopes, adjacent structures). Although sediment dredging is specified for limited portions of the SIB Project Area, application of the remedial technology decision tree (Figure 1-3) may result in applying this technology within portions of the zone slated for sediment dredging via future maintenance dredging in the navigation channel. That result will depend on the relation between required navigation depth and the vertical extent of contamination.

Designing and evaluating this element of the RD will require the following data and analysis:

- Current and future navigational use of the waterway and associated depth requirements,
- Bathymetry,
- Sediment characterization of vertical and horizontal distribution of COCs,
- Condition assessment of adjacent shoreline structures,
- Geotechnical analysis of adjacent submerged and bank slopes,
- Geotechnical analysis of bedded sediments to assess settlement under a cap,
- Distribution of debris and utilities within and adjacent to the dredge area,
- Hydrodynamics and sediment dynamics analysis,
- Evaluation of cap effectiveness,
- Porewater upwelling locations
- Porewater chemistry, and
- Evaluation of cap stability.

### **1.3.4 Sediment Capping**

The ROD specifies sediment capping within the SIB Project Area near portions of the shoreline along Mocks Bottom and Swan Island and around in-water structures at the end of the Swan Island peninsula. Sediment capping may be applied strategically to provide a protective remedy close to and under in-water structures where COC concentrations are too high for effective application of ENR and other active remedial technologies (e.g., dredging) would not be feasible or compatible with shoreline structures or adjacent slopes due to structural or geotechnical concerns.

Designing and evaluating this element of the RD will require the following data and analysis:

- Bathymetry and topography,
- Sediment characterization of horizontal distribution of COCs,
- Condition assessment of adjacent shoreline structures,
- Geotechnical analysis of adjacent submerged slopes and bank slopes,
- Geotechnical analysis of bedded sediments to assess settlement under a cap,
- Hydrodynamics and sediment dynamics analysis,
- Evaluation of cap effectiveness,
- Porewater upwelling locations,
- Porewater chemistry, and
- Evaluation of cap stability.

### **1.3.5 Enhanced Natural Recovery**

ENR is specified within portions of the SIB Project Area along the Mocks Bottom shoreline waterward and adjacent to MNR areas. ENR is also specified for an approximately 12-acre area at the mouth of the SIB lagoon within the transitional zone between the main river and the SIB. ENR is commonly applied where surface sediment COC concentrations are relatively low, but natural processes (e.g., sediment deposition and mixing) proceed too slowly to rely on MNR to meet remedial goals. ENR relies on placement of a specified thickness of clean, typically sandy material that effectively dilutes surface concentrations of COCs and reduces exposure for ecological and human receptors. Designing and evaluating this element of the RD will require the following data and analysis:

- Bathymetry,
- Sediment characterization of horizontal distribution of COCs, and
- Hydrodynamics and sediment dynamics analysis.

While the ROD technology application decision tree identifies ENR as the selected technology for areas within the project area that are outside of the SMA, the results of specific, approved sampling locations and parameters compared to applicable CULs will be the basis for determining which specific locations will be subject to ENR and which specific locations will be subject to MNR. Criteria that will be used to specify locations for ENR are summarized as follows:

- Located outside the SMA but within the project area;
- COC concentrations in surface sediments exceed CULs but are less than RALs; and
- Sediment deposition occurs at too slow a rate for MNR to be protective. Threshold rate will be determined as part of the sediment transport modeling analysis.

### **1.3.6 Monitored Natural Recovery**

MNR is specified within limited shallow areas along the head of the SIB lagoon and along the Mocks Bottom shoreline. MNR is a passive component of the remediation approach that relies on natural processes, generally related to sediment dynamics, to attenuate relatively low levels of COCs. MNR is often specified in areas where an active remedy could impact aquatic habitat as a means of minimizing such impacts. While MNR does not require design, there are data and

analysis requirements relevant to evaluating the effectiveness of MNR as a component of the remedy. Those data and analysis needs are:

- Sediment deposition rates;
- Analysis of sediment resuspension, transport, and deposition; and
- Habitat conditions survey.

#### **1.4 PDI WORK PLAN ORGANIZATIONAL OVERVIEW**

This section provides a brief overview of the organization of this PDI Work Plan.

Section 1.0 presents an overall introduction including a clear purpose statement for this work plan and a description of the approach and strategy for planning and conducting the PDI so that it results in the data and analysis necessary to develop an effective and sustainable RD.

Section 2.0 provides an overview of existing conditions including a discussion of the site background and history; a description of the present-day site layout, land use, and activities in and around the SIB waterway; and a discussion of the CSM and its application to the specific context in the SIB Project Area.

Section 3.0 documents the data gap analysis. Data gaps were determined by:

- Identifying the information necessary to support the RD,
- Assessing available data and analysis for applicability, and
- Comparing what is needed to what is available and applicable.

Where appropriate and helpful, summary tables are used to show side-by-side comparisons of these steps. The data gap analysis is organized by specific technical categories relevant to different elements of the design including both design development and design evaluation. Data gaps identified in the SAR (HGL, 2021a) are integrated with the data gaps identified for design.

Section 4.0 proposes the approach to addressing the identified data and analysis gaps. The proposed data and analysis work plan is organized by the same categories of data collection and analysis used in Section 3.0 so that the parallel structure allows for easy reference between those sections.

Section 5.0 presents the PDI Management Plan that proposes how the performing Parties and the RD team will manage implementation of the PDI and documentation of the results in coordination with EPA.

Section 6.0 proposes a preliminary schedule for the individual technical deliverables that will document the results of the PDI.

Section 7.0 documents the references cited throughout this PDI Work Plan.

## 1.5 SUPPORTING DOCUMENTS FOR THIS PDI WORK PLAN

The supporting planning documents, including the FSP, Quality Assurance Project Plan (QAPP), Health and Safety Plan (HASP), and Emergency Response Plan (ERP) are included as appendices.

This PDI Work Plan is supported by the essential planning documents listed below. These documents were developed according to EPA guidance and in compliance with the requirements specified in the ASAOC (EPA, 2021a).

- **Appendix A, Field Sampling Plan**—The FSP supports the PDI sampling within the SIB Project Area and the SIB Upland Area and provides details for field sampling locations and procedures for the planned PDI project tasks. The FSP also addresses the field data collection needs identified in the SAR (HGL, 2021a) to inform the evaluation of potential recontamination.
- **Appendix B, Quality Assurance Project Plan**—The QAPP provides quality control (QC) elements to satisfy the data quality objectives for each task specified in this PDI Work Plan. The protocols established in the QAPP are necessary to ensure the data generated is of a sufficient quality to support development of valid conclusions. EPA’s 7-step data quality objective process for each media will be applied, as appropriate, in this plan (EPA, 2006).
- **Appendix C, Health and Safety Plan**—The HASP identifies and describes physical, chemical, and biological hazards relevant to each planned field task, and provides hazard mitigation techniques to address these hazards.
- **Appendix D, Emergency Response Plan**—The ERP will be used in the event of an accident or emergency during PDI fieldwork.

## 1.6 IMPORTANT DEFINITIONS

The following important definitions are used in the PDI for PHSS SIB Project Area:

**Cleanup Levels (CULs)** are “the long-term contaminant concentrations that need to be achieved by the remedy to meet RAOs [remedial action objectives]” (EPA, 2017a). CULs were established in the ROD for multiple media and COCs based on human and ecological risk thresholds, applicable or relevant and appropriate requirements, and background concentrations (in sediment only). For riverbank soil or sediment, when risk-based CULs were less than background concentrations for a given contaminant, background concentrations were selected as the CUL. PHSS CULs are based on Errata #2 Table 17 of the PHSS ROD (EPA, 2020).

**Contaminants of Concern (COCs)** are contaminants that "contribute a significant amount of risk to the human and ecological receptors evaluated" (EPA, 2017a). The focused COCs are those of highest prevalence, toxicity, and significance at PHSS and consist of PCBs, PAHs, dioxin/furans, and DDx. The focused and additional COCs are listed in Table 21 of Appendix II of the PHSS ROD (EPA, 2017a), updated in the ESD (EPA, 2019a).

**Recontamination Potential Chemicals (RPCs)** are the chemicals that pose a risk of recontamination in the SIB Project Area and were identified by screening existing surface sediment data against PHSS CULs. RPCs will be determined by a screening process to be documented in the final SAR. RPCs will be based on an assessment of all available sediment, riverbank, groundwater, and stormwater data screened against the applicable ROD Table 17 CULs as modified by the 2019 ESD and the 2020 Errata #2 memorandum, and ROD Table 21 RALs and PTW thresholds.

**Remedial Action Levels (RALs)** are contaminant-specific sediment concentrations specified for the focused COCs in Table 21 of Appendix II of the PHSS ROD (EPA, 2017a). RALs are used to determine where active remediation is required. RALs in the SIB Project Area are higher than sitewide values for RALs in nearshore areas because the SIB Project Area is outside of the navigation channel. For the purposes of this document, RALs will refer specifically to those applicable to the SIB Project Area and these sitewide RALs in ROD Table 21 apply to the SIB Project Area.

**Principal Threat Waste (PTW)** is mobile and/or toxic source material containing hazardous substances. PTW thresholds are based on a 10<sup>-3</sup> risk level (highly toxic), except for not reliably contained PTW (chlorobenzene and naphthalene or the non-aqueous phase liquid PTW and may require treatment prior to disposal). PTW thresholds are listed in Table 21 of Appendix II of the PHSS ROD, updated in the ESD (EPA, 2017a; EPA, 2019a).

**Sediment Management Areas (SMAs)** are the regions of PHSS in which RAL and/or PTW threshold values are exceeded. The term is defined in the ROD as "areas where containment or removal technologies were considered to immediately reduce risks upon implementation [and] where natural recovery is not occurring or is not likely to be effective in reducing concentrations of COCs within a reasonable time frame ... the presence of PTW and in-situ treatment areas for PTW were used to delineate SMAs [and] the FS (Feasibility Study) alternatives were developed using focused COCs" (EPA, 2017a). Further, per EPA's *Remedial Design Guidance and Considerations* document, "a SMA will be delineated by surface and subsurface contamination above RALs and principal threat waste (PTW) thresholds" (EPA, 2021b).

## **2.0 EXISTING CONDITIONS OVERVIEW**

PHSS extends along 9.9 miles of the lower Willamette River in Portland, Oregon, from RM 1.9 to RM 11.8. EPA listed PHSS on the National Priorities List in December 2000. A Remedial Investigation (RI) and FS were performed between 2001 and 2016 (EPA, 2016a; EPA, 2016b). On January 3, 2017, EPA issued a ROD selecting a remedy to be implemented for long-term cleanup of PHSS (EPA, 2017a). However, because the data utilized to develop the RI/FS and ROD were up to 20 years old, the ROD explicitly called for a post-ROD sampling effort to evaluate and update conditions prior to the development of the RD. EPA has approved data collected since the ROD as part of the PHSS PDI and Baseline Sampling Study (AECOM and Geosyntec, 2019). The data from this Portland Harbor-wide PDI will be used in the development of the RD to refine SMAs, select appropriate remedial technologies, and identify uncontrolled sources of recontamination for the SIB. For all relevant media, a summary will be included that contains the nature and extent of COC contamination, contamination sources, and migration pathways.

Existing conditions within the SIB Project Area and its surroundings provide context for understanding and applying existing data and analysis and identifying additional data needs to support development of the RD. The SIB Project Area is described below with high-level descriptions of the waterway and riverbanks, in-water and shoreline activities, upland properties in the project area vicinity, and a brief overview of site development history. Preliminary refinements to the CSM are presented and discussed to anticipate and guide portions of this PDI Work Plan that will be applied to refining the CSM so the RD will be sustainable and effective within the context of natural processes and human activities in and around the SIB Project Area.

The Willamette River provides critical habitat for fish, wildlife, aquatic and terrestrial plants and birds, and supports several endangered salmon runs as stated in the ROD. The Willamette River is important to many Native American tribes. Six federally recognized tribes are party to the 2001 Memorandum of Understanding established by EPA after listing PHSS on the National Priority List as described in ROD Section 1 (EPA, 2017a). Tribes maintain rights through Treaties with the United States to hunting, fishing, and certain gathering activities. The history of tribal presence in the region and within the PHSS site indicates there may be cultural and archeological resources within the project area. The archaeological survey conducted during the RI/FS will be utilized to highlight areas of interest in the SIB for consideration when developing the RD.

### **2.1 SWAN ISLAND BASIN PROJECT AREA**

The SIB Project Area (Figure 1-2) is the active cleanup area between approximately RM 8.1 and RM 9.2 on the northeast side of the Willamette River in Portland, Oregon. The SIB Project Area is approximately 1.1 miles in length and 117 acres in size. Within the SIB Project Area boundaries, the RD will address contaminated sediments in the riverbed and contaminated soils on erosion-prone riverbanks extending to the top of the bank.

The SIB Project Area is bounded by uplands of Swan Island and Mocks Bottom to the southwest and northeast, respectively, and by dredge fill at the head of the basin. Except for slopes along the riverbanks, land surface within the SIB Project Area is generally flat, with elevations of about 30 to 40 feet (ft) NGVD29. Land uses within and adjacent to the SIB Project Area consist of light and heavy industrial uses and commercial uses (Figure 1-4). Mixed (residential/commercial) and

residential only land uses are located outside but in close vicinity to the SIB Project Area. The SIB is an active navigable industrial waterway, and the shoreline hosts many structures supporting light and heavy industrial activities.

### **2.1.1 Waterway and Riverbanks**

The SIB is a quiescent waterway that is backwatered from the main Willamette River Channel. Currents within the interior of the SIB move slowly in response to daily tidal cycles and during flooding events when rising river levels raise the water elevation with the SIB. The interior waterway is approximately 1 mile long and 650 ft wide. Typical water depths within the SIB range from 20 to 35 ft with shallowest depths in the interior of the lagoon and deepest areas located at the transition to the main river channel downstream of the end of the Swan Island Peninsula. The SIB is a freshwater waterbody, but it is influenced by daily tides that cause water surface elevation to vary typically over a 3- to 4-ft range with a maximum range of approximately 6 ft.

The riverbanks within the SIB are predominantly armored with riprap or protected from erosion by bulkheads or other shoreline structures. The SIB lagoon is roughly rectangular in shape, and the shoreline in its entirety was constructed by fill placement and other modification that occurred over several decades. The shoreline at the head of the lagoon includes a sandy beach with sparse vegetation, and there are vegetated and bare soil banks in a more natural condition along a larger portion of the Mocks Bottom shoreline.

### **2.1.2 In-water and Shoreline Activities**

The waterway within the SIB Project Area supports commercial/industrial, recreational, and government vessel traffic related to the ongoing uses of the shoreline. Shoreline facilities support light and heavy industrial uses, vessel mooring, U.S. Coast Guard operations, and public access.

### **2.1.3 Upland Properties**

Upland areas around the SIB Project Area that discharge stormwater runoff to the SIB include approximately 588 acres of mostly impervious area with primarily light industrial uses (Figure 1-4). Stormwater discharges from these upland areas to the SIB from five city of Portland municipal outfall basins (M-1, M-2, M-3, S-1, and S-2), six Port of Portland outfall basins, as well as multiple private outfalls (Figure 1-4).

### **2.1.4 Site Development History**

The SIB was historically part of the main channel of the Willamette River and Swan Island was not connected to the shoreline area known as Mocks Bottom. First explored by Lewis and Clark in 1806 and originally charted as Willow Island, Swan Island was awarded to Lemuel Hendrickson as one of four pioneer land claims in the Portland area in the 1840s (Oregon Department of Environmental Quality [ODEQ], 2016). A natural bar repeatedly formed at the island, which required maintenance dredging from the 1870s through 1920s to keep the ship channels open (Oregon Historical Society [OHS], 2014). The main river channel flowed east of the island adjacent to the marshy lowlands of Mocks Bottom, curving into the base of the high bluff, above which is Mock's Crest.

In 1922, the Port of Portland had acquired Swan Island (ODEQ, 2016) and received approval in 1927 to close the main navigation channel creating a lagoon or basin (OHS, 2014). The Port of Portland developed Swan Island beginning in 1923, when the main navigation channel of the Willamette River was relocated to the west side of the island. River sediments dredged as part of the project were deposited on Swan Island to raise the surface elevation and construct a causeway connecting the island to the eastern shore of the river. This allowed industrial development of the island as Portland's first municipal airport.

The Mocks Bottom area also was subsequently filled with dredge fill for industrial development. Figure 2-1 shows the fill history. By 1946, most of Swan Island had been developed and most of the Mocks Bottom area had been filled (Maul Foster and Alongi, Inc., 2009; Bridgewater Group, Inc. [Bridgewater], 2011). The Port of Portland estimated that more than 13 million cubic yards of dredged material was placed in the 1920s and 1930s to create commercial and industrial space from the former Mocks Bottom marshlands (Engineering World, 1920). Since initial development of Swan Island and Mocks Bottom, additional placement of dredge fill has periodically occurred, including between about late 1950s and 1960s in the Mocks Bottom area and to create the southwest part of Swan Island, and in 1984 when about 4.8 million cubic yards of dredge material was placed at the head of the basin.

By 1940, the airport outgrew the island and was relocated, and Henry Kaiser's ship building operations began and continued throughout World War II (OHS, 2014). Temporary housing for workers was built on Swan Island and in Mocks Bottom for the workforce that built T2 Tankers between 1942 and 1945 (ODEQ, 2016). Kaiser continued to perform work at the shipyard between the end of the war and 1947. Consolidated Builders reportedly conducted ship dismantling post-war between 1947 and 1949 (ODEQ, 2016).

After the war, the Port of Portland acquired the shipyard from the United States and made it available for use by local ship repair companies, increasing the industrial manufacturing, shipping, and transportation focus of the area in the 1950s (City of Portland, 2013b). Heavy industrial uses continue at the Portland Shipyard on Swan Island (Figure 1-4). The Mocks Bottom area was developed for light industrial and commercial use in the 1960s through the 1990s (City of Portland, 2013b).

## **2.2 SWAN ISLAND BASIN CONCEPTUAL SITE MODEL**

The CSM presented in ROD Figures 3, 4, and 5 applies to the entire PHSS. The CSM fulfills an essential purpose that centers on identifying and describing, at a conceptual level, the essential elements of the site that are relevant to COC sources, release mechanisms, transport and exposure pathways, and ecological and human receptors. The CSM portrays these elements and how they relate and interact with one another in the context of the site considering physical, chemical, and ecological processes as well as human activities. Refinements to the CSM as it specifically applies to the SIB Project Area are necessary to ensure that the remedy will be sustainable and effective in the context of the SIB and not subject to future recontamination.

The SIB Project Area is physically distinct from the main river because most of the project area is a backwatered slip that is not subject to the higher flow velocities and resulting forces that transport sediments and COCs and substantially modify the physical configuration of the riverbed and

riverbanks. The SIB Project Area is physically more stable in comparison to the main river. Sediment deposition and accumulation proceeds slowly, while currents and other physical processes are broadly too weak to physically alter the riverbed within most of the SIB Project Area. While the riverbed and riverbanks within the SIB Project Area are typically not subjected to scouring forces from river currents (Coast & Harbor Engineering, 2013), like those in the main river, waves generated by vessel traffic in the lagoon likely mobilize sediment and potentially cause erosion in riverbank locations not protected by structure or armoring. The majority of the lagoon is privately owned; however, there is public access via a beach and boat ramp at the head of the lagoon. The distinct physical attributes of the SIB affect the relations and relative effects of many elements of the CSM in comparison to the main river and other parts of PHSS.

Multiple data collection efforts and studies proposed as part of the PDI will provide the necessary information and analysis to further refine the CSM and provide a quantitative analytical basis for applying the CSM to developing and evaluating the RD in its applicable context. Initial refinements to the CSM specific to the SIB Project Area are identified and described below along with their implications for development of the RD.

### **2.2.1 Quiescent Backwater Conditions are Prevalent Within SIB**

During peak flow conditions in the river, as well as during periods of low flow that result in maximum tidal exchange, current velocities within the SIB interior are typically less than 0.1 ft per second. Current velocities are larger in the mouth of the SIB between the navigation channel and the shipyard, reaching up to roughly 1 ft per second, and can exceed 1 ft per second in the main channel (Coast & Harbor Engineering, 2013). The waterway is backwatered by the main river water surface elevations and subject to freshwater tidal influence and water surface elevations that rise and fall with variable flood stages. During flood stages, the SIB does not convey flood flows moving in the main river because it is a backwater channel. Even during large flood events, the interior of the SIB remains quiescent, with river flow-induced current velocities less than 0.1 ft per second (Coast & Harbor Engineering, 2013).

### **2.2.2 Natural River Sediment Deposition and River-Induced Scour are Limited by Low Energy Hydrodynamics in the SIB Interior**

Quiescent river flow conditions in the SIB interior result in low sediment deposition rates (neutral, between -2.5 to +2.5 centimeters per year), as demonstrated by comparison of hydrographic surveys from both 2002 to 2009 and from 2009 to 2018 (AECOM and Geosyntec, 2019). Riverbed scour due to river currents alone is likely negligible, based on observed small current velocities and modeled currents less than 0.1 ft per second (Coast & Harbor Engineering, 2013). While river-induced sediment mobilization is limited, some degree of localized sediment mobilization, resuspension, and scour likely result from vessel traffic within the SIB. However, transport of these sediments is also likely to be limited due to low ambient current speeds.

### **2.2.3 The Mouth of the SIB is a Physical Process Transition Zone**

With respect to both hydrodynamics and sediment dynamics, the mouth of the SIB is a transition zone between the higher flow velocities and sediment transport rates prevalent within the main river and the quiescent conditions typical of the interior of the lagoon. This transition zone is

limited to a discrete definable area, and it may be used to determine the extent to which sediment may be exchanged between the main river and the SIB Project Area. Comparison of bathymetric surveys showed that sediment deposition may be as much as 1.5 ft over 10 years within the transition zone (Geosyntec, 2019).

#### **2.2.4 Stormwater Outfalls are the Primary Connected Pathway from Upland Sources to SIB Sediments**

There are five city of Portland municipal stormwater system outfalls that discharge to the SIB Project Area. Those outfalls drain most of the surrounding upland area in Mocks Bottom and Swan Island. A much larger number of private outfalls with small drainage areas convey stormwater runoff from private properties along the margins of the waterway. The majority of the SIB upland is privately owned; however, there is public access via a beach and boat ramp at the head of the lagoon. The CSM published in the ROD (EPA, 2017a) identifies eight final release mechanisms that were evaluated as potential recontamination transport pathways between the upland source areas and SIB sediment in the SAR (HGL, 2021). That evaluation applied existing data to compare the relative magnitude of the potential future COC loading to SIB via each transport pathway. That analysis concluded that based on potential loading, stormwater discharges to SIB were the primary connected pathway between upland sources and SIB for potential recontamination of SIB sediments. This finding applies to future recontamination, and the relative importance of contaminant transport pathways under past conditions was likely different. The SAR determined that stormwater is not the only potential pathway for recontamination. The findings in the SAR are preliminary and based on existing data. This analysis will be revisited when the SAR is updated after the PDI data collection efforts address the data gaps identified in the SAR.

#### **2.2.5 Dredging History Informs Interpretation and Application of Sediment Characterization Data**

Understanding the history of dredging within the SIB Project Area is necessary to interpret sediment characterization data and apply it to the RD. In 1923, the Port of Portland began to relocate the main navigation channel of the Willamette River from the east side of Swan Island to the west side. In 1927, a causeway of filled land was built between Mocks Bottom and Swan Island, closing off the channel and creating a still-water basin. Following the closing of the SIB, dredging occurred as part of upland development. For example, in the early 1940s, shipways were dredged to create a dry dock basin. Major dredging occurred in the SIB in the 1940s through the 1970s.

The Lower Willamette Group compiled dredge information, including dredge areas, depths, date, and volume in the Lower Willamette from 1980 through 2001 as documented in Table 3-3 and Map 2-2 of the 2004 Programmatic Work Plan (Integral et. al., 2004) and GIS file metadata. The Lower Willamette Group reported the following dredging events in SIB:

- 1981, Dry Dock 3 maintenance;
- 1985, Berth 315 maintenance;
- 1985, Berths 301 to 305 maintenance;
- 1986, Berths 306 to 308 maintenance; and
- 1992, Dry Docks 1 and 4 maintenance.

Most recently, Vigor Industrial, LLC (Vigor) dredged and capped sediments at the dry dock basin north of Pier D in July 2015 to accommodate the Vigorous dry dock. Records for the shipyard from 1981 to present are well researched and documented in LWG work. However, specific dredging information is not available prior to the 1970s for the SIB and may not be complete for non-shipyard facilities.

### **2.2.6 Waterway Uses Determine Navigation Requirements**

The waterway within the SIB Project Area supports a wide range of vessel traffic related to the ongoing uses of the shoreline. The shoreline facilities support light and heavy industrial uses, vessel mooring, U.S. Coast Guard operations, and public access. The current and future navigational needs for the SIB waterway are not clearly specified or documented, but they are determined by the current and future uses of the waterway associated with the collective shoreline properties. Maintenance dredge depths are specified for the Federal Navigation Channel maintained by USACE. That Federal Navigation Channel is located within the main Willamette River channel throughout much of PHSS as depicted on Figure 1-1, and it does not extend into the SIB Project Area. Navigation depth requirements within the SIB lagoon are not specified as part of the Federal Navigation Channel, and the current and future navigation depth requirements for the SIB Project Area are a data gap.

### 3.0 DATA GAP ANALYSIS

The data gap analysis was completed following the approach outlined in Section 1.0:

- (1) Identify the data and analysis needed, based on the conceptual design approach and strategy, to inform the development and evaluation of a RD for a sustainable and effective remedy;
- (2) Compile and evaluate available applicable data and analysis aligned with the specified data and analysis needs; and
- (3) Identify data and analysis gaps based on the comparison of what is needed to what is available.

All collected data and technical information will be based upon the need for this data and technical information required to support the evaluation with the appropriate level remedy compliant with the *Remedial Design Guidance and Considerations* document (EPA, 2021b).

The data gap analysis is organized by categories of data and analysis needed to develop and evaluate the design. Each sub-section that follows contains a summary of the data required, data available at the time of this report, and data gaps that were identified as needing to be addressed as part of the PDI. The following types of data were considered for use on the project:

1. Surface/Subsurface Sediment Contaminant Concentrations
2. Porewater Upwelling Locations
3. Stormwater Discharge
4. Riverbank Characterization
5. Bathymetry and Topography
6. Geotechnical Site Characterization
7. Shoreline and Overwater Structures and Activities
8. Existing Utilities and Debris
9. Hydrodynamics and Sediment Dynamics
10. Flood Impact Evaluation
11. Habitat Conditions

#### 3.1 SURFACE/SUBSURFACE SEDIMENT CONTAMINANT CONCENTRATIONS

Surface and subsurface sediment RAL and PTW exceedances define SMAs in PHSS. For RM 8.5E overall, total PCBs, 2,3,7,8-tetrachlorodibenzo-p-dioxin, and 1,2,3,7,8-pentachlorodibenzo-p-dioxin (PeCDD) RAL exceedances define the ROD SMA in the SIB Project Area (EPA, 2017a). In addition to the 2017 ROD, additional surface and subsurface samples have been collected as part of the following investigations:

- Kleinfelder, 2015. Sediment Sampling Data Report, Portland Harbor, Portland, Oregon. Prepared for de maximis inc. 1 June.
- Geosyntec, 2016. Sediment Sampling Data Report, Swan Island Lagoon, Portland, Oregon. Prepared for The Marine Group, LLC and BAE Systems San Diego Ship Repair, Inc. August 12.
- AECOM and Geosyntec, 2019. PDI Evaluation Report, Portland Harbor Pre-Remedial Design Investigation and Baseline Sampling. Prepared for United States Environmental Protection Agency, Region 10.
- Pacific Groundwater Group, 2019. Surface and Subsurface Sediment Field Sampling and Data Report, Swan Island Lagoon, Portland Harbor Superfund Site. Prepared for Daimler Trucks North America LLC (DTNA).
- Pacific Groundwater Group, 2019. Surface and Subsurface Sediment Field Sampling and Data Report, Swan Island Lagoon, Portland Harbor Superfund Site. Prepared for de maximis, inc.

These samples are depicted on Figures 3-1a to 3-1d, except the Kleinfelder data, and show generally good surface spatial coverage within the ROD SMA boundary with less coverage at the mouth and along the northern Mocks Bottom boundary. EPA has not accepted the data set from the Kleinfelder investigation in 2015 and the RD will not rely on that data. All sediment sample locations shown on Figures 3-1a to 3-1d are presented in Table 3-1, including individual sample results for each COC, sample identifications, sample dates, sample depths, and data qualifiers. Note that future maintenance dredge (FMD) areas portrayed on Figures 3-1a to 3-1d differ from what was shown in the ROD, and EPA has not yet accepted these areas for use in the RD. Section 2.2.6 of this PDI Work Plan identifies current and future navigation depth requirements for the SIB Project Area as a data gap. The approximate FMD areas shown in Figures 3-1a to 3-1d are preliminary and based on preliminary information provided by a subset of the shoreline property users. The FMD areas that will be used to inform the RD will be mapped based on the results of the proposed facility owner/operator interviews, which will include a survey of waterway users (see Section 4.11.2 of this PDI Work Plan). Any revisions to the map of FMD areas will be reported to EPA in the PDI Evaluation Report and subject to EPA review and acceptance prior to using them to inform technology applications and RD development.

The data gap analysis method for both surface and subsurface sediment data gaps overlay a 150-by 150-ft grid with existing sediment data and identifies grid cells that lack data (Figures 3-2 and 3-3). The 150-ft spacing is consistent with the spacing described in *Remedial Design Guidelines and Considerations* (EPA, 2021b) and the grid spacing used in the RM9W and Willamette Cove project areas, and effective spacing in the Terminal 4 project area. Table 3-2 presents a summary of existing source documents for surface and subsurface sediment contamination concentrations and identifies data gaps.

Proposed sediment samples would address identified sediment data gaps to meet the following three goals:

- Update the horizontal and vertical extent of contamination within the SIB Project Area,
- Refine the SMA footprint and technology assignments in the SIB, and
- Delineate the extent of PTW.

In addition to characterizing the extent of sediment contamination, sediment chemistry must be characterized to evaluate the potential for short-term contaminant releases during dredging operations. That evaluation is typically informed by dredge elutriate testing, which would require bulk sediment samples.

### **3.1.1 Surface Sediment Contaminant Concentrations**

Additional data is required to define the SMA as the basis of RD. Surface sediment data gaps will be filled to delineate the SMA boundary in several locations where data is not complete. These “step out” data gaps are defined grid cells that overlap or border the SMA boundary but lack any existing surface sediment sample data. The FSP (Appendix A) provides additional detail regarding sample locations, collection procedures, and analysis.

Figure 3-2 presents surface samples that have been collected in the SIB SMA overlain by a 150-ft square grid. This figure shows that of the 70 grid cells that define the ROD SMA border, 47 (67 percent) have existing data. The 29 “step out” data gaps will be targeted for sampling to provide a basis for refining the SMA boundaries. The proposed surface samples are located within grid cells using judgement to achieve approximate 150-ft spacings.

The sampling plan shown on FSP Figures 4-3 and 4-4 will address COC-specific data gaps. The boundary of the ROD SMA including step-outs and targeted sampling where buried and post-RI/FS exceedances have been identified. The top interval of cores will be archived, and some of these may be necessary to fill in COC-specific data gaps. These potential data gaps are listed in Section 4.2.2 of the FSP and will be determined on a case-by-case basis after the initial round of sample results are received to meet 150-ft spacing along the SMA boundary for each COC. EPA may be consulted for review on the necessity of analyzing archived material in some cases. The proposed analytical schedule includes 3 weeks for lab analysis following sample receipt, followed by 3 weeks for data validation. Upon receipt of validated data, the data will be reviewed within 60 days and recommendations for further analysis of archived material will be sent to EPA.

Specific sampling methodologies are presented as part of the FSP (Appendix A). Conceptually, surface samples will be collected from the top foot of each grid cell lacking a surface sample. Target coordinates will be defined by randomly generating x and y coordinates within each cell, then manually adjusting the coordinates as necessary to better meet 150-ft spacing criteria and in some cases to move sample locations away from areas already heavily sampled. Final coordinates will be reported after fieldwork is complete. Where grid cells have data gaps in both surface and subsurface sediments, a single core will be collected for both surface and subsurface samples.

### **3.1.2 Subsurface Sediment Contaminant Concentrations**

Fewer subsurface or core samples have been collected within the SIB Project Area compared to the number of surface samples. Figure 3-3 shows the ROD subsurface sample locations and additional core locations sampled during the post-ROD investigations listed in Section 3.1. Thus,

data gaps exist for subsurface sediment, and additional subsurface samples are required to support RD in selecting and designing remedial technologies.

Data gaps are identified using the same grid approach and judgement for location within each grid cell applied for surface sediments to identify where grid cells lack subsurface data and additional cores are needed (Figure 3-3). In addition to targeting areas within and along the border of the ROD SMA, 17 grid cells are targeted for sampling outside the ROD SMA. These represent grid cells with buried or suspected subsurface contamination exceeding RAL or PTW criteria outside the ROD SMA and areas with large subsurface data gaps. Additionally, ten core locations within the ROD SMA are extended to target penetration depths of 20 ft in areas with subsurface RAL and PTW exceedances that do not have well-constrained depths of contamination.

The FSP (Appendix A) includes sampling details about number of samples, depths, and analytes. Conceptually, core locations are identified in each grid cell lacking existing subsurface data by randomly generating x, y coordinates for core collection within each cell. These random coordinates are then manually adjusted within grid cells, as necessary, to support a 150-ft spacing between existing and planned sample locations and in some cases to distance a random sample location away from nearby existing sample data in neighboring grid cells. Final coordinates will be reported after fieldwork is complete. Each collected core will be sampled at 1-ft intervals from the sediment surface to a depth of 10 ft, as described in the *Remedial Design Guidance and Considerations* document (EPA, 2021b). Surface and subsurface samples will be collected from the same location as required.

### **3.2 POREWATER UPWELLING LOCATIONS**

Identification and mapping of locations within the SIB Project Area where upward porewater migration occurs is necessary to inform the RD. More specifically, this information supports the evaluation and design of engineered sediment caps in areas where subsurface contaminated sediments may be left in place below an engineered sediment cap or other remedial technology that addresses the sediment surface. A map of porewater upwelling locations is needed to determine the locations where capping may not be effective or, alternatively, locations where a different engineered cap design may be required to prevent breakthrough of COCs through the cap due to upward migration of porewater. During the design phase, the porewater upwelling map will be layered with the proposed locations for engineered sediment capping to evaluate the need for additional data collection and/or analysis to determine the pressure gradients that drive porewater migration and the resulting porewater velocities and flow rates.

Porewater data was not available within the SIB Project Area to address these needs. The physical configuration of the waterway and surrounding landscape combined with the history of dredging and filling to form both the landscape and the waterway suggest that porewater migration is likely a limited process in this setting. That inference is not sufficient for RD, and field data and analysis are necessary to either confirm this or identify and characterize areas where porewater migration could affect RD.

### 3.3 STORMWATER DISCHARGE

There are five public, seven Port of Portland, and multiple private stormwater outfalls that discharge to the SIB Project Area from the surrounding upland areas. The status of discharges from some of the private outfalls is unknown and will need to be evaluated as part of the PDI to provide information necessary to complete the SAR (HGL, 2021a). ROD Table 17 COCs, including focused COCs, were detected in stormwater and stormwater solids in public and select private outfall basins at concentrations that exceed the surface water and/or sediment CULs and/or RALs. In addition, dioxins/furans have not been adequately characterized either within the stormwater conveyance systems, or at the many sites in the upland area around the SIB Project Area that are contributing runoff to these stormwater collection and conveyance systems.

For the reasons above, the collection of additional stormwater and solids data within city of Portland outfall basins M-1, M-2, M-3, S-1, and S-2, and select private outfall basins, is necessary, to provide updated analytical data representative of current conditions, determine source control sufficiency to complete the SAR, and for modeling to assess recontamination potential for SIB (HGL, 2021a). The specific data collection and analysis approach to evaluate inputs from upland sites, as well as current concentrations of ROD Table 17 COCs in stormwater for the outfall basins, is provided in Section 4.3. Completion of the ongoing source control and investigation activities at upland properties continues to be within the jurisdiction of ODEQ with coordination and input from EPA, except at two sites owned by the U.S. Government (U.S. Navy and Marine Reserve Center [Environmental Cleanup Site Information (ECSI) 5109] and adjacent U.S. Coast Guard Marine Safety Unit [ECSI 1338]), where EPA is the regulatory authority for source control.

### 3.4 RIVERBANK CHARACTERIZATION

Pursuant to the *Guidance for River Bank Characterizations and Evaluations at the Portland Harbor Superfund Site* (EPA, 2019b), EPA has assumed oversight of the riverbank erosion pathway from ODEQ. The ROD (EPA, 2017a) identified three riverbanks within the SIB Project Area as areas with known contamination that exceed RALs and/or CULs for various ROD COCs, including focused COCs, in the SIB Project Area. The locations of those riverbanks are shown on Figure 1-2 and described as follows:

- One riverbank along the Portland Shipyard property on Swan Island adjacent to the SIB Project Area (1,487 lineal feet of bulkheads, a historical wooden retaining wall, and/or riprap below ordinary high water mark (OHWM) and vegetated soil above OHWM) (ECSI 271);
- The riverbank along the Portland Shipyard property's Dry Dock Basin and Ballast Water Treatment Plant on the end of the Swan Island peninsula (224 lineal feet of engineered bank consisting of riprap below OHWM and vegetated soil above OHWM); and
- One 911-ft-long riverbank, armored with riprap below OHWM and vegetated soil above OHWM, along the U.S. Navy and Marine Reserve Center (ECSI 5109) in the Mocks Bottom portion of the SIB Upland Area.

Two non-ROD riverbanks were identified based on ROD CUL exceedances in soil during previous investigations: A 713-ft-long, unarmored, sand riverbank was identified at the head of SIB, and a

587-ft-long armored bank along the Port of Portland’s N. Lagoon Avenue property adjacent to SIB.

The SAR assigned an initial source control sufficiency status of “uncontrolled” to all shoreline properties because (1) few riverbanks adjacent to the SIB Project Area have been adequately characterized (SAR Figure 6-1 [HGL, 2021a]); (2) there is a potential need for RA on shorelines where COCs are present in soils; and (3) contaminated riverbanks are at risk of erosion and could be uncontrolled sources of recontamination. If an in-river sediment SMA does not extend to the toe of the riverbank in portions of the SIB shoreline (i.e., is not contiguous with the riverbank) and the riverbank materials are not erodible, the source control sufficiency status may be downgraded for the riverbank erosion pathway in those areas. Regardless of source control sufficiency status assigned to a particular riverbank, EPA guidance for riverbanks (EPA, 2019) requires that the entire lateral extent of COCs in the riverbank be characterized.

Data was not available to characterize riverbank stability and the presence of COCs in riverbank soil sufficiently to determine their source control sufficiency status, identify riverbank locations that would need to be addressed as part of the RD, or inform design development for riverbank remediation where required. Section 4.4 of this PDI Work Plan describes the objectives of the proposed field reconnaissance and data to be collected to fill riverbank data gaps.

The RD will include measures to remediate the three riverbanks and any other riverbanks within the SIB Project Area identified in the ROD as needing RA. According to the ROD, these riverbanks will be determined based on the combined results of the first and second phases of the riverbank evaluation. The selected remedy for riverbanks will minimize erosion and transport of riverbank materials contaminated above CULs, thereby minimizing recontamination potential through a riverbank erosion pathway. Alteration of any riverbank will be discussed and coordinated with shoreline property owners during the RD.

### **3.5 BATHYMETRY AND TOPOGRAPHY**

Table 3-3 summarizes the data gap analysis performed to ensure adequate information on bathymetry and topography data will be available during and after the PDI. The data gap analysis results for bathymetry and topography indicate that a new multibeam bathymetry survey of the SIB Project Area is required, but typical topographic surveying is not required for the PDI. Additional topographic surveying will be performed as part of design for selected areas that will be identified during development of the Basis of Design Report (BODR). This bathymetric surveying data collection effort must be completed to support various analyses on hydrodynamics and sediment dynamics, cap stability, riverbank stability, and overall RD. Additional topographic surveying will be performed later as part of the RD for selected areas if necessary.

### **3.6 GEOTECHNICAL SITE CHARACTERIZATION**

Table 3-4 summarizes the data gap analysis performed to ensure adequate geotechnical site characterization data will be available during and after the PDI. Results of the data gap analysis indicate that a project-specific geotechnical site investigation is required to adequately characterize the SIB Project Area. Specific data gaps identified include site soil stratigraphy, groundwater conditions, geotechnical design parameters, geologic hazards, and seismic design parameters.

Geotechnical site characterization field efforts are intended to support evaluation of recontamination, cap stability, and overall RD. Additional specific design applications of geotechnical information include assessment of shoreline stability, and evaluation of settlement in locations where engineered sediment capping may be specified.

### **3.7 SHORELINE AND OVERWATER STRUCTURES AND ACTIVITIES**

Table 3-5 summarizes the data gap analysis performed to confirm adequate information on shoreline and overwater structures will be available following the PDI. Results of the data gap analysis for overwater structures indicate that available as-built information for all the overwater structures, available existing recent condition assessment results, intended future use information, and repair history information should be collected. It is anticipated that not all this data will be available during the PDI; therefore, inspections, condition assessments, and structural evaluations are also recommended.

The priority for characterizing conditions of shoreline structures (revetments/bulkheads) to inform RD development is dictated by the nature and proximity of the remedial technology specified near or under each structure. The selected alternative in the ROD specifies active remediation (either sediment capping or dredging) along all the Swan Island shoreline on the southwest side of the lagoon. MNR or ENR are specified for the shoreline along the head of the lagoon and along about 80 percent of the Mocks Bottom shoreline on the northeast side of the lagoon. Sediment capping or dredge with capping is specified for about 20 percent of the Mocks Bottom shoreline at the northeast end of the lagoon. Complete and detailed information about shoreline structures (revetments/bulkheads) is most important along the shorelines where active remediation is specified. Along shorelines where MNR is specified, the need for detailed assessment of shoreline structures (revetments/bulkheads) will be determined by the distance from the structure to the edge of active remediation, and whether the specified active remediation has the potential to affect the structure.

The known overwater activities for the SIB shoreline are typical of large ports. The materials that are transferred to/from the structures are not known to contain SIB RPCs, except petroleum hydrocarbons used for fueling and maintenance of vessels. To the best of the Parties' knowledge, shoreline and upland facilities currently operate pursuant to best management practices (BMPs), and currently exhibit standard practices of care designed to reduce spills into the river. However, overwater activities along the SIB shoreline will be further evaluated as potential recontamination concerns during the RD.

The current and future navigational needs for the SIB waterway are not known. Maintenance dredge depths are specified for the Federal Navigation Channel maintained by USACE. That Federal Navigation Channel is located within the main Willamette River channel and does not extend into the SIB Project Area. Navigation depth requirements within the SIB lagoon are not specified as part of the Federal Navigation Channel, and the current and future navigation depth requirements for the SIB Project Area are a data gap.

Leaching or abrasion of the in-water structures are potential pathways for associated contaminants to reach nearby sediment. There has not been a comprehensive survey of in-water structures or debris in the SIB Project Area, and there is no facility-specific information regarding the presence

or absence of contaminants on these structures. A screening level visual inspection of readily accessible in-water structures will be conducted as part of shoreline and overwater structures data collection activities. To the extent that wooden and painted steel structures will remain in place as part of the remedy, they may need to be assessed during the RD.

Shoreline and overwater structures data collection is intended to support recontamination evaluation and detailed engineering studies for overall RD, including information necessary to evaluate functionality and condition of the structures. Precursors to overwater activities evaluation would be owner/operator interviews, incident reports, or BMP documentation.

### **3.8 EXISTING UTILITIES AND DEBRIS**

Table 3-6 summarizes the data gap analysis performed to ensure adequate information on existing utilities and debris will be available during and after the PDI. Sediment dredging design requires information characterizing the location and nature of debris. That information informs selection of dredge equipment, material handling requirements, and determination of whether large debris must be picked out in some areas before dredging proceeds. Utility locations within the project area must be clearly known to identify and either avoid or resolve conflicts between the RA and utility locations. Utility conflicts may need to be resolved by utility protection and/or relocation as part of RA. The data gap analysis results for existing utilities and debris indicate that a new survey program consisting of sub-bottom profiling, magnetometer survey, and side-scan sonar is required, in addition to desktop study to locate and document potential obstacles to be encountered and/or removed during RA. Utilities under consideration include power, communications, water/stormwater, or other similar systems.

### **3.9 HYDRODYNAMICS AND SEDIMENT DYNAMICS**

Table 3-7 summarizes the data gap analysis performed to ensure adequate information on hydrodynamics and sediment dynamics will be available during and after the PDI. The data gap analysis results for hydrodynamics and sediment dynamics indicate that a new program consisting of current, water level, suspended sediment, wind-wave, and vessel wake measurements is required, in addition to desktop studies and numerical modeling to evaluate sediment movements (recontamination potential, cap stability). Hydrodynamics and sediment dynamics data collection and PDI studies are necessary to support completion of the SAR (HGL, 2021a) with respect to in-water sources and pathways including sediment resuspension, transport and deposition of COCs in sediments delivered from upstream sources, and fate and transport of COCs discharged from outfalls. The same studies will be applied during the RD to support evaluation of sediment resuspension and scour, recontamination potential, sediment cap stability, riverbank stability, and other aspects of overall RD.

### **3.10 FLOOD IMPACT EVALUATION**

Flood impact evaluation is necessary to confirm that a selected remedial strategy does not result in exacerbated flooding in the surrounding area during heavy rain events. Data required for flood impact evaluation include hydrologic conditions (river discharges and downstream tidal elevations), updated bathymetry both with and without the proposed remedy included, and numerical modeling results for analysis of flooding impacts. No existing flood impact data is

available because the remedy has not been determined. Discharge and tidal elevation data is available from the network of U.S. Geological Survey (USGS) gages and National Oceanic and Atmospheric Administration (NOAA) tide gages, respectively. Federal Emergency Management Agency flood elevation data is available, which is critical for use as input to numerical modeling efforts. Sufficient field data is available during the PDI; however, numerical modeling must be performed during the PDI to provide flood impact evaluation conclusions.

### **3.11 HABITAT CONDITIONS**

EPA has authority to direct the evaluation of habitat impacts to meet the substantive requirements of Clean Water Act (CWA) Section 404. EPA has initiated programmatic consultation with National Marine Fisheries Service (NMFS) for the sitewide cleanup and will direct the project area-specific evaluations under the Endangered Species Act and CWA Section 404. Habitat Equivalency Analysis (HEA) is the tool that EPA will use to evaluate habitat pre-and post-remediation for the purposes of complying with CWA Section 404 and, in coordination with NMFS, in compliance with the Endangered Species Act. The purpose of the habitat conditions characterization would be to collect the data needed to inform an HEA-based approach to comparing pre- and post-remediation habitat conditions. EPA, as the decision maker, will ensure implementation of all reasonable NMFS requirements. Similarly, EPA will determine how CWA requirements will be implemented with input from ODEQ.

The study area for the habitat conditions characterization will include the riparian area on the riverbank extending into the shallow water area along the shoreline within the SIB Project Area. NMFS defines the shallow water area from 0 to -15 ft Columbia River Datum. This vertical extent of the habitat conditions study is divided into five zones:

- Riparian area – areas above ordinary high water and less than 400 ft from the active channel margin (ACM).
- ACM – the area between ordinary high water and ordinary low water.
- Shallow water – the area between 0 to -15 ft Columbia River Datum.
- Deep water – the area deeper than -15 ft Columbia River Datum.
- Off-channel areas – tributaries to the main waterway.

Data needs to characterize the riparian area include vegetation, substrate, location with respect to historical floodplain, slope, presence of buildings, structures, and riprap.

Data needs to characterize the ACM are depth, substrate, presence of riprap, sheetpile/seawall, pilings, and suspended and floating structures.

Data needs to characterize the shallow water area are depth, substrate, presence of riprap, sheetpile/seawall, pilings, and suspended and floating structures.

Data needs to characterize the deep water area are depth, substrate, presence of riprap, sheetpile/seawall, pilings, and suspended floating structures.

Data needs to characterize the off-channel areas are tributary water temperature and position relative to main channel substrate.

Habitat data collection would occur on transects spaced at 150 ft-intervals along the shoreline using photo documentation of habitat conditions at a frequency sufficient to fully describe habitat conditions for input into the HEA. HEA development will require the acreages and conditions of each habitat area where remedial activities will occur. This work overlaps extensively with the data needs for riverbank evaluation, and HGL intends to coordinate the habitat survey and riverbank characterization survey to ensure consistency and efficiency.

Available data exists to characterize both bank conditions and near shore shallow zone conditions to some extent, but there are zones where existing data is sparse or absent. Similarly with the riverbanks, there is data for portions of the shoreline, but there are sections of the riverbank that have sparse or no data.

There are no precursors to the habitat characterization work, but it would be most efficient to coordinate the work with any riverbank evaluation survey efforts. The riverbank survey, overwater and shoreline structure surveys, bathymetry surveys, and surface sediment sampling would all be potential sources of data to support completion of the habitat characterization.

## 4.0 PRE-DESIGN INVESTIGATION APPROACH

The data gap analysis identified data gaps to be filled during the PDI. This data is required to support development of the RD as described in Section 3.0 for each data and analysis need. In addition to informing RD development, components of the PDI will also support completion of the source control sufficiency assessment as documented in the SAR (HGL, 2021a), SMA delineation refinements, refinement of the CSM, and application of the Technology Application Decision Tree (Figure 1-3) to determine remedial technology assignments. Data gaps are summarized in Table 4-1 along with the proposed data collection and analysis recommended to address those gaps. Data gaps specifically identified in the SAR are called out within the table and a crosswalk is provided to identify the PDI Work Plan section that addresses each SAR data gap. Data gaps will be addressed using a combination of field data collection (e.g., sampling and surveying) and engineering analysis. This section describes the approach to both the field sampling efforts and engineering studies. Additional details on proposed field sampling are provided in the FSP (Appendix A).

### 4.1 SUBSURFACE/SURFACE SEDIMENT CONCENTRATIONS

Both surface and subsurface sediment sampling will be performed to refine the lateral and vertical extent of contamination as the basis of RD. As discussed in Section 3.1, Figures 3-2 and 3-3 identify the data gaps used to determine the proposed surface and subsurface sediment sampling locations.

Surface sediment data gaps will be filled with the analysis of 30 new samples, 29 of which represent “step out” samples used to refine the delineation of the SMA boundary. Of these 30 samples, 4 locations have existing subsurface data and therefore do not require core sampling. Those four surface samples will be collected to meet 150-ft spacing criteria, and a fifth surface sample will be collected targeting an outlier PAH exceedance from 2002 near the head of Swan Island Lagoon. In total, surface samples will be collected at 5 locations by grab sampler. The remaining 25 samples will be collected as the uppermost interval of proposed new cores, from 0 to 1 ft in depth below mudline. Proposed surface sample locations are shown on Figure 4-3 of the FSP (Appendix A).

Subsurface sediment data gaps are addressed with the analysis of 179 cores, with 2 additional cores collected and archived for a total of 181 cores. Core samples will be collected in 1-ft intervals from 1 to 6 ft in depth for 10-foot cores and 1 to 15 ft in depth of 20-foot cores, for a total of 985 Phase I samples. The uppermost interval (0 to 1 ft) for 156 of the cores will be frozen and archived for potential future analyses in case RD development identifies the need for additional surface sediment data. Analysis will most likely be triggered by the identification of COC-specific data gaps after the first phase of sample results are received, but additional archived material may be analyzed as necessary, and in consultation with EPA as needed, to support RD.

The uppermost interval for 25 of the cores, as previously noted, will be sampled and analyzed to fill surface sediment data gaps. Cores will also be sampled at 1-ft intervals from 6 to 10 ft, frozen, and archived for potential future analyses after updated preliminary technology assignments are identified. Ten locations are identified for targeting 20-foot core lengths, located in grid cells N0, J8, E18, C19, E20, E22, E27, E33, D35, and F35. These locations will aid in filling depth-of-contamination data gaps within the SMA boundary. The 20-foot core locations are selected to

target areas with PTW exceedances that are unbounded in depth near or exceeding 10 feet below mudline, and to a lesser extent areas with unbounded RAL exceedances. Locations were further selected to target areas where the expected remedial technologies are most uncertain, starting near Berth 305 and continuing to the Head of SIB. Eight 20-foot cores will be collected in and near this area, from grid cell columns 18 to 35. A ninth 20-foot core will be collected in the Dry Dock Basin near an unbounded PCB PTW exceedance in grid cell J8, and a tenth 20-foot core will be collected in grid cell N0 just outside the Swan Island Sediment Decision Unit near an unbounded PCB PTW exceedance in grid cell N1. The two archived cores will be collected from grid cells H0 and I0 and analyzed depending on any identified RAL and PTW exceedances in neighboring cells H1 and I1.

Analysis of archived subsurface sediment will most likely be triggered by the need to constrain the depth of contamination with two consecutive 1-ft intervals below the deepest CUL exceedance after the first phase of sample results are received. It may not be necessary to perform analysis on every core to constrain depth of contamination, and EPA will be consulted on any reductions to the analysis of archived samples. Additional archived material may be analyzed as necessary, and in consultation with EPA as needed, to support RD. For example, an anomalously high COC result may warrant analysis of nearby (horizontally and vertically) archived material.

Three samples for dredge elutriate testing shall be collected from grid cells F14, D5, and C20 to evaluate the potential for short-term contaminant releases during dredging operations. The samples will be collected in accordance with SOP 403.08 Sediment Sampling (FSP Appendix A) and tested for all ROD Table 17 Surface Water COCs. The results from dredge elutriate testing shall be evaluated against both chronic and acute water quality criteria as defined in FSP Section 4.2.5.

## **4.2 POREWATER UPWELLING LOCATION SURVEY**

This task proposes to conduct a vessel-mounted instrument survey to measure temperature and conductivity contrasts in porewater and overlying surface water using a Trident Probe along transects within the SIB Project Area. Identification and mapping of locations within the SIB Project Area where upward porewater migration occurs is needed to address data gaps identified in Section 3.2. A map of porewater upwelling locations is needed to determine the locations where capping may not be effective or, alternatively, locations where adjustments to engineered cap design may be required to prevent breakthrough of COCs through the cap due to upward migration of porewater through contaminated sediments below the cap.

The survey would collect temperature and conductance measurements in porewater and overlying surface water along the transects shown in Figure 4-1a. The standard operating procedure for the Trident Probe is in Appendix A of the FSP. For the temperature sensor, areas of groundwater seepage may appear either as warm or cold contrast to the surface water depending on the seasonal and site characteristics. For the conductivity sensor, groundwater conductivity is typically higher than that measured in surface water in rivers. The detection of upwelling zones between surface water and groundwater will be based primarily on measurements of conductivity contrast and secondarily on measurements of temperature contrast (Coastal Monitoring Associates, 2020).

The proposed stations are closer together for nearshore areas and further apart away from shore. Distances between stations were also adjusted for the presence of permanent or semi-permanent structures (Figure 4-1a). The proposed survey assumes station distances of no more than 50 ft near

the shore and no more than 100 ft away from the shore. Specifically, the proposed survey assumes fifteen 800-ft-wide transects across SIB (with up to 10 stations each where no permanent structures are present) and two 400-ft-wide transects at the head of SIB (8 stations) for a total of up to 158 stations.

Measurements may deviate from the transects, as needed, to map those areas with the largest temperature and conductance gradients between sediment and overlying surface water. Measurements may deviate from the proposed transect lines if a strong contrast in surface water and porewater conductivity measurements is recorded in one area along a transect to delineate the extent of that contrast on and around the transect line area and to quantify variability within the potential upwelling zone. The stronger the difference in measurements, the more measurements will be collected in that area to map the extent of the upwelling zone(s). These additional stations will be within 50 ft of the previous station. In addition, deviations from proposed station locations may occur if the substrate is too hard to manually drive the Trident Probe into the sediment or vessels or other over-water features are present during the survey.

The timing of the investigation will be planned during the time of the year when the river surface elevations are dropping, has less tidal fluctuations (neap tides), temperature contrasts between surface water and groundwater are greatest, and seasonal groundwater elevations are higher than river elevations. Figure 4-1b of this PDI Work Plan shows groundwater elevations relative to river elevations for those wells closest to the basin versus the river channel. Some groundwater elevations consistently plot close to river elevations, reflecting high connectivity with the river, and, as a result, are influenced by mean river level and potentially the tides. Groundwater elevations were higher than river elevations in December 2001, March 2002, July 2002, October 2002, March 2003, September 2003, December 2003, January 2005, October 2005, September 2006, October 2006, January 2007, and September 2007. In addition to a comparison of groundwater elevations relative to river elevations, the timeframe for discharge mapping is also related to a temperature signal difference between groundwater and surface water. This difference generally stronger during the winter (groundwater warmer than surface water) and summer (groundwater cooler than surface water) and weaker during transition periods of fall and spring based on Gravity Marine and Coastal Monitoring Associates professional experience on rivers in the Pacific Northwest. For example, in late February 2022, river temperatures were 6 to 7 degrees Celsius, and are expected to provide a good contrast with groundwater temperatures (estimated to be between 12 and 15 degrees Celsius [Bridgewater, 2020]). Also in late February 2022, discharge and gauge heights were low (below 25<sup>th</sup> percentile) with low river conditions (<https://waterdata.usgs.gov/nwis/uv?14211720>). The survey period was selected to correspond as closely as possible to neap tide conditions when tidal fluctuations are relatively small (~2 ft). The subsurface probe depth was also selected to be at 18 inches, deep enough to be minimally affected by tidal fluctuations. As a result, the upwelling survey is proposed for February and March 2022.

Limitations of the upwelling study are related to the screening-level nature of the measurements, and the limited temporal coverage of the data. While conductivity and temperature provide a good indicator of potential upwelling zones, they can be influenced by processes other than groundwater upwelling and thus need to be considered as a screening level indicator of potential upwelling zones only, and not a quantitative measure of upwelling rates. Quantification of upwelling rates generally requires different methodologies that are most effectively applied after the potential upwelling zones have been identified. The screening survey will be conducted during conditions

that are present in February – March 2022 and are thus primarily indicative of that time period. As discussed above, that period is expected to be a favorable time to detect upwelling using conductivity and temperature. However, the actual conditions that are present during the measurement period may vary from what is expected. In addition, seasonal and other temporal variations in river levels and groundwater levels may influence the nature and extent of upwelling zones. To the extent that uncertainty remains in identification of potential upwelling zones following the winter measurement event, some level of verification during the summer period may be considered.

The survey described above is the first phase of a two-phase approach to characterizing porewater chemistry and groundwater upwelling rates. Porewater sampling and analysis will be included in Phase 2 to characterize porewater chemistry. After the results of the Phase 1 porewater upwelling mapping effort are completed, HGL will use those results to prepare a sampling and analysis plan for characterizing porewater chemistry and migration rates in the areas where groundwater seepage occurs. That future porewater sampling and analysis plan will be provided to EPA for review as an addendum to the PDI Work Plan and FSP.

The upwelling survey results will be overlaid on proposed cap areas and used to identify future collection stations for quantitative measurements of seepage rates in proposed cap areas for cap modeling. Seepage rate data collection methods and locations will be described in a future porewater sampling and analysis plan that will be provided to EPA for review as an addendum to the PDI Work Plan and FSP.

A cap treatability study is tentatively planned as a component of the design and evaluation of sediment capping within the SIB Project Area. That cap treatability study is not included as part of the current PDI Work Plan. It will be developed on a parallel track with the PDI and documented in a draft Cap Treatability Study Work Plan that will be submitted to EPA for review tentatively October 2022 to allow consideration of the Phase 1 porewater survey results in developing that work plan. Preliminary concepts for the cap treatability study envision laboratory tests designed to compare alternatives for cap composition, chemical treatment amendments, and thickness.

### **4.3 STORMWATER OUTFALL AND CONVEYANCE SYSTEM SAMPLING**

This task includes the collection of stormwater and stormwater solids samples within municipal and private conveyance systems that drain to the SIB Project Area. Proposed sampling of municipal conveyance systems will include the city of Portland outfalls M-1, M-2, M-3 S-1, and S-2 conveyance systems. Some ROD Table 17 COCs in stormwater and stormwater solids were detected in city outfall basins at concentrations exceeding surface water and sediment CULs and/or RALs.<sup>2</sup> As further described in Section 6.1 of the SAR (HGL, 2021a), evaluation of available data indicates that additional sampling within city and private outfall basins is warranted for the following reasons:

- Data for stormwater solids collected before some source control measures (SCMs) were implemented in the city's outfall basins indicate that PCBs exceeded the surface water CUL in all SIB city outfall basins and the PCB RAL in stormwater solids in some locations.

- Determine whether these solids could recontaminate future remedial caps and ENR and MNR areas.
- Recent sampling of stormwater and stormwater solids COC concentrations in city and private systems at levels that, although similar to other PHSS heavy industrial sites, still exceed the applicable surface water and riverbank/sediment CULs.
  - o Stormwater or solids sampling data are not available for private outfalls adjacent to areas that have had ROD COC CUL and RAL concentration exceedances in surface sediment.
  - o In addition, dioxins and furans are present in surface sediment data in the vicinity of these city outfalls. However, dioxins/furans have not been adequately characterized either within the stormwater conveyance systems, or at the many sites in the SIB Upland Area that are contributing stormwater to these conveyance systems discharging into the SIB Project Area.

This PDI Work Plan includes a task to identify and address other data gaps for stormwater outfalls. Data will be used to evaluate the effects of stormwater with ROD CUL or RAL exceedances within the SIB Project Area. Figure 4-2 shows the proposed manhole sample locations within city outfall basins M-1, M-2, M-3, S-1, and S-2. Table 4-2 summarizes invert elevations of proposed sampling locations in the city's system as well as possible alternative sample locations representative of basin discharges, if access constraints or possible backflow are identified.

Most SIB outfalls are submerged at least part of the year, causing flow reversals within the pipe, that would confound stormwater loading evaluations. Therefore, the manhole access location closest to the target outfalls was selected as the representative "End of Pipe" sample location for the high-volume, time-weighted sampling (HVS) (i.e., manholes AAM107/AAM104, AAM165, AAQ003/AAQ004<sup>2</sup>). Table 4-2 identifies alternate HVS locations to use if the primary manholes are flooded because of a high tide or storm event and cannot be sampled (i.e., the SIB river stage elevation as measured via a water level probe installed in SIB and corrected to the Morrison Street Bridge Corrected Datum is predicted to be higher than a pipe invert elevation). Comparisons of pipe invert elevations to river elevations will be completed before mobilizing to the field so that the necessary preparations (e.g., traffic control, access notifications) can be completed in advance.

The HVS sampling methodology, which will be followed using the Gravity Marine PR2900 system, is a time-weighted sampling method that targets sample collection during qualifying storms that occur when the river stage is below the manhole sump elevation. This approach is expected to ensure that samples are representative of stormwater discharges and are not influenced by river water backing up into the pipe.

---

<sup>2</sup> High-volume water samples are collected to quantify concentrations of targeted organic chemicals (e.g., dioxins/furans, PCBs, and pesticides) that could be present at levels too low to be detected using conventional sampling methods. This method also allows for quantification of hydrophobic organic chemicals in the suspended particle and dissolved phases of the water column. The HVS equipment system, the Gravity Marine PR2900, was approved by EPA for use on the PHSS PDI and baseline sampling surface water sampling event (AECOM and Geosyntec, 2019). This sampling methodology is a form of flow-weighted sampling.

HVS at these key locations will include the collection of time-weighted stormwater, stormwater solids, and storm flow data during three representative storm events over an approximate 9-month period and to add the data to the SEDCAM recontamination model to predict future total COC loading to the SIB Project Area. In addition, in-line sediment traps will be installed in the laterals to the manholes to collect solids that will be composited into samples representing two separate periods (wet season from December 2021 through June 2022 and dry season from July through October 2022) for comparison to the data collected during the three individual HVS storm events. The dry season deployment may be terminated early if wet weather before the end of October is predicted. In addition, flow meters will be installed prior to sampling and continuously log data during the sediment trap deployment period and during HVS events. Prior to deployment, HGL will confirm that manhole sampling will occur when river elevations are sufficiently below manhole elevations.

The proposed stormwater sampling plan also includes the collection of manual grab samples at the same locations as the in-line sediment traps (prior to deployment) and at manholes further up-pipe within the city conveyance system. The rationale for collecting manual grab samples from laterals in subbasins of each city outfall basin, prior to sediment deployment, is to collect materials present in the line in the unlikely event that no solids are collected in the sediment traps. These solids will be archived (frozen) for potential future analyses. Data from either the sediment traps or the grab samples will be added to the SEDCAM recontamination model to inform the relative Table 17 ROD COC load from each major sub-basin (i.e., each sub-basin of the outfall basins in the city conveyance system). The data will identify potential ongoing sources of contamination by evaluating stormwater solids data downstream of upland sites.

The sampling locations proposed for in-line and grab stormwater solids are shown on Figure 4-2, listed in Table 4-2, and include:

- Three laterals into manhole AAM104<sup>3</sup> from subbasins in the city outfall basin M-1 (map identification is OFM-1);
- Three laterals into manhole AAM169 from subbasins in the city outfall basin M-2 (OFM-2);
- Two laterals into AAQ004<sup>4</sup> from subbasins in the city outfall basin M-3 (OFM-3);
- Two laterals entering manhole AAM131 from two subbasins within the city outfall basin S-1 (OFS-1); and
- Two laterals entering manhole AAP957 from two subbasins within the city outfall basin S-2 (OFS-2).

---

<sup>3</sup> In-line sediment trap deployment and collection of manual solids samples are not proposed at this location due to historical and likely future river backflow. If proposed field reconnaissance during high tide indicates that a sediment trap can be installed above the highest river elevation, then a sediment trap will be installed at this location with the inlet above the highest river elevation. The proposed HVS monitoring and solids sampling location may be adjusted to AAM104 where river backflow is less likely (i.e., pipe invert elevation of 13.01 ft MBDC versus 6.58 ft MBDC at AAM107).

<sup>4</sup> While manhole AAQ003 is closer to OFM-3, its pipe invert elevation is less than the river elevation range during the wet season (3.11 ft versus 4 to 10 ft MBDC). As a result, the proposed monitoring location was adjusted.

In addition to city conveyance system monitoring, private systems will be instrumented with autosamplers to collect grab samples and flow data during qualifying storm events to assess the need for upland source control (Figure 4-2). The private stormwater systems with direct discharges to SIB that will be sampled, and the rationale for sampling each system include:

- The U.S. Coast Guard Marine Safety Unit (historical pre-SCM CUL exceedances in stormwater and stormwater solids and adjacent to RAL and PTW threshold exceedances in sediment);
- ATC Leasing (historical CUL exceedances in stormwater and adjacent to RAL exceedances in sediment);
- Barge Eagle Inc./Swan Island Dock Company (historical CUL exceedances in stormwater and adjacent to CUL exceedances in sediment);
- North Basin Watumull LLC/Swan Island Dock Company (no stormwater or stormwater solids data, historical pesticide releases, and adjacent to RAL exceedances in sediment);
- DTNA Corp 5 Wind Tunnel property (no stormwater or solids data and adjacent to RAL exceedances in sediment); and
- Port of Portland property on North Lagoon Avenue (former Swan Island Upland Facility Operable Unit [OU] 3) (historical CUL exceedances in stormwater and stormwater solids, discharges to ROD riverbank, and adjacent to RAL exceedances in sediment).

While ROD CUL and RAL exceedances are present in surface sediment adjacent to the Portland Shipyard, Vigor is implementing SCMs under an ODEQ Consent Order and Tier 2 measures under its National Pollutant Discharge Elimination System (NPDES) 1200-Z stormwater permit to control CUL exceedances in its stormwater discharge. Vigor is also sampling stormwater for dioxin/furans pursuant to the ODEQ Consent Order (Floyd|Snider, 2020e). Figures E-5 and E-6 in Appendix E of the 2021 SAR show the Portland Shipyard's layout and stormwater drainage areas (HGL, 2021a). The Portland Shipyard outfalls that historically discharged to the basin in the SIB Project Area include 2 that were rerouted to a treatment facility in 2017 and 18 that will be rerouted for electrocoagulation (EC) treatment in 2021. Two additional outfalls that discharged to the Portland Shipyard's drydock area were rerouted for treatment in 2017. Treated effluent from the rerouted outfalls discharges to the main channel of the Willamette River at berth 313 (see Figure 3-1). All the outfall basins in the shipyard are treated, either through active treatment in the EC system (outfall basins Q, S, S1, E, and F) or through passive treatment, including the outfalls on Pier D and the scuppers on Pier C. The exact types of passive treatment (e.g., double rain barrels, custom catch basin inserts, and Grattix boxes) are described in Vigor's Tier II Corrective Action Report and its Monitoring and Performance Evaluation Reports (Floyd|Snider, 2020a and 2020b). Currently, five outfall basins (M1, G, Pier C, Q, and R) discharge treated stormwater to the SIB Project Area. Discharges are monitored as part of NPDES 1200-Z industrial stormwater permit requirements. One outfall basin (M) discharges stormwater to the city's S-1 conveyance system, which will be monitored as part of the PDI.

Additional data on the proposed sample locations, sampling methodology, analytical approach, and schedule is provided in the FSP (Appendix A) and QAPP (Appendix B).

#### 4.4 RIVERBANK CHARACTERIZATION

Riverbank characterization is needed to fulfill three purposes: (1) address data gaps necessary to complete the source control sufficiency assessment, (2) determine the full extent of contamination exceeding the ROD CULs, and (3) provide data necessary to support RD for remediation of contaminated riverbank soils (EPA, 2019b).

Riverbank characterization will be performed in two phases, with one field mobilization each, to identify and characterize the types of materials present in the riverbanks, locate, and delineate areas of potentially erodible sediments, sample grain sizes (through subsequent laboratory sieve analysis), and locate areas of geotechnical movement (slope rotational failure, settlement). This PDI Work Plan addresses only the first phase. The first phase will include an assessment survey of the entire riverbank within the SIB Project Area and completion of a bank stability analysis using the BANCS model, including Bank Erosion Hazard Index and near bank stress determinations. The first phase of the proposed riverbank characterization includes visually inspecting the riverbank and material types to determine input parameters for the BANCS evaluation. After completing this inspection, HGL will prepare a riverbank soil sampling plan as an addendum to this PDI Work Plan. The addendum will include the data quality objectives and proposed sampling locations. The first phase assessment survey will be performed when water levels are at their lowest in SIB (anticipated for Fall 2021 or early 2022). Chemical characterization will be used to meet the ROD objectives; identify the nature of contamination relative to CULs, RALs, and PTW thresholds; and inform the RD when contamination is present (EPA, 2019).

The proposed two-phased characterization will develop data required to determine which riverbank areas need further detailed erodibility/stability assessments by coastal and geotechnical engineers during the PDI. This data will also be used to delineate riverbank areas susceptible to erosion for future use in the RD. Coordinates of erodible and non-erodible areas will be mapped using hand-held GPS units, backed up with field notes on tablets. During the second phase of the riverbank characterization, riverbank soil sampling for chemical characterization will be performed at 126 riverbank transect locations (see Figure 3-2), including a surface soil sample and a subsurface soil sample at each sampling location along the transects (e.g., top, face, and toe of bank [mean low water]). Riverbank soil sampling will be deferred until the proposed first phase riverbank survey has been completed. EPA guidance for riverbanks (EPA, 2019) requires that the entire lateral extent of the riverbank be characterized.

The proposed two-phased approach to riverbank characterization includes the following sequential steps:

1. Assemble available topographic and nearshore bathymetric maps and light detection and ranging (LiDAR) maps to obtain topographic inputs for the BANCS analysis;
2. Conduct a riverbank assessment survey to characterize existing bank conditions, collect data sufficient to run a BANCS analysis for 126 transect locations to calculate bank erosion indices and near bank stress values, and identify locations where riverbank soil sampling is feasible based on material types;
3. Compile riverbank assessment data and perform a BANCS evaluation to calculate the degree of erodibility of the banks;

4. Identify riverbank soil sampling locations based on the results of the riverbank assessment survey, results of the BANCS evaluation, and review of existing riverbank soil data;
5. Prepare a riverbank soil sampling plan and provide it to EPA for review and approval prior to initiating sampling; and
6. Conduct riverbank soil sampling.

This PDI Work Plan includes only the first phase of the riverbank characterization. The first phase includes the Step 1 riverbank assessment survey, the Step 2 data collection to support the BANCS modeling analysis, and the Step 3 data compilation and runs of the BANCS model pursuant to the Stormwater and Riverbank Assessment and Sampling Plan (HGL, 2021a). For the second phase of the work, the specific approach for Steps 4 through 6, conducted during the second phase of the riverbank characterization, will be documented in the Final PDI Work Plan and in the riverbank soil sampling plan addendum, which will be prepared after the riverbank assessment survey and BANCS evaluation steps have been completed.

For riverbank areas with existing data and adjacent to sediment SMAs, the concentrations of ROD COCs at those areas will dictate how they are incorporated into the BODR as follows (after Section 4.1.2, Table 1 and Figure 4 of Appendix D of the *Remedial Design Guidelines and Considerations* document [EPA, 2021a]):

- If ROD Table 17 COC concentrations are less than the CULs, no action will be necessary.
- If ROD Table 17 COC concentrations are above the CULs, the vertical and lateral extent of the exceedances will be delineated, a BANCS analysis (or equivalent erodibility evaluation) will be performed to identify erodible and non-erodible conditions, and a lines of evidence approach will be presented to evaluate whether RAO 9<sup>5</sup> can be achieved by a planned action.
- If ROD Table 21 focused COC concentrations are between the CULs and the RALs, the vertical and lateral extent of the exceedances will be delineated, a BANCS analysis (or equivalent erodibility evaluation) will be performed to identify erodible and non-erodible conditions, and the need for RD for the riverbank will be assessed based on whether the materials exceeding CULs are erodible.
- If ROD Table 21 focused COC concentrations exceed the RALs but not the ROD Table 21 COC concentrations PTW thresholds, the vertical and lateral extent of the exceedances will be delineated, a BANCS analysis (or equivalent erodibility evaluation) will be performed to identify erodible and non-erodible conditions, as noted above, and the RD for the riverbank will be designed in accordance with the requirements of the ROD. Remedial technologies to address contaminated riverbank soils may include removal of contaminated soils and/or capping of contaminated soils, supplemented with bank stabilization to resist erosion (e.g., from stormwater runoff, tidal fluctuations, and propeller wash).

---

<sup>5</sup> RAO 9 - River Banks: Reduce migration of COCs in river banks to sediment and surface water such that levels are acceptable in sediment and surface water for human health and ecological exposures (EPA, 2017a).

- If ROD Table 21 COC concentrations exceed the PTW thresholds, the vertical and lateral extent of the exceedances will be delineated, a BANCS analysis (or equivalent erodibility evaluation) will be performed to identify erodible and non-erodible conditions, as noted above, and the RD for the riverbank will be designed in accordance with the requirements of the ROD. Remedial technologies to address contaminated riverbank soils may include removal of contaminated soils and/or capping of contaminated soils, supplemented with bank stabilization to resist erosion (e.g., from stormwater runoff, tidal fluctuations, and propeller wash).

Characterization data was available for only three shoreline properties in the SIB Upland Area: city property with a public boat ramp at the head of SIB, and two former OUs of the Swan Island Upland Facility (Portland Shipyard [OU1] and Port property on N. Lagoon Avenue [OU3]). Sampling results for these three sites were evaluated in Section 6.0 and Appendix E of the SAR (HGL, 2021a). ROD CULs for riverbank soil and in-water sediment and PCB RAL exceedances were identified. Detected concentrations of metals, PCBs, and polycyclic hydrocarbons exceeded the ROD CULs at the Portland Shipyard, and PCBs exceeded the RAL and PTW threshold. Because the lateral extents of the exceedances were not defined and all ROD COCs were not analyzed, these conditions were identified as data gaps for the PDI, and additional characterization has been proposed.

Remediation of impacted riverbanks with adjacent SMAs will become part of the preferred remedial approach presented in the BODR so that the connections between riverbanks and adjacent sediment remediation are accounted for and addressed in an efficient overall design strategy.

#### **4.5 BATHYMETRIC AND TOPOGRAPHIC SURVEYS**

Bathymetric data collection will address the need for a new complete survey data set identified as a data gap in Section 3.5 and Table 3-2. The new bathymetry data will support hydrodynamics and sediment dynamics data collection, PDI engineering studies, and RD. Bathymetric data acquisition will result in a complete elevation surface in the areas of potential remedy using multibeam survey techniques. Reasonable bottom elevation approximations will be made in areas where data collection is not feasible (e.g., under permanently moored vessels or large pile-restrained floats), such as filling data gaps using interpolation based on observed slopes, or filling with previous data if analysis shows recent changes are minimal. Side-scan sonar and sub-bottom profiling being performed at different times may also be used to help address bottom elevation data gaps to the extent feasible. Extents of the proposed multibeam bathymetry survey are shown in Figure 4-3. Bathymetric data collection will be conducted in accordance with applicable requirements specified in the ROD, ASAOC, and *Remedial Design Guidelines and Considerations* document (EPA, 2021b). Further details are provided in the FSP (Appendix A).

Previously available topographic survey data will be used during the PDI for recontamination evaluation, cap/riverbank stability evaluation, and identification of debris. Data available from existing LiDAR (Oregon LiDAR Consortium, 2014) and the proposed laser scan (see Section 4.7) are deemed sufficient in coverage, resolution, and quality for these purposes during the PDI phase of the project. Later, during preliminary and final engineering design, a densely spaced topographic survey will be required at targeted locations. This approach provides the detailed survey data required for design and avoids sitewide topographic surveying that would be costly

and of insufficient value. Existing property line data from [www.portlandmaps.com](http://www.portlandmaps.com) can be used for the PDI phase of the project if required; therefore, no property line surveying is proposed.

Bathymetry data collection will not require specific permits or access agreements with property owners, nor does it rely on any other data collection efforts or PDI studies.

#### 4.6 GEOTECHNICAL SAMPLING

Geotechnical sampling will be performed both in water and in the uplands to identify and characterize the types of soil present at the site, develop estimates for relevant geotechnical engineering design parameters, identify geotechnical hazards, and assess overall ground conditions. Ground condition assessment results will inform structure condition assessments, as well as riverbank stability, cap stability, and cap settlement. Geotechnical sampling will address data gaps identified in Section 3.6 and Table 3-3, and will be based on the following:

- An evaluation of available geotechnical data, including:
  - Existing site-specific geotechnical data and reports;
  - Soil survey maps and data (e.g., Natural Resources Conservation Service);
  - Geologic maps and fault maps (e.g., USGS and Oregon Department of Geology and Mineral Industries); and
  - Historic topographic maps and aerial photographs (e.g., USGS and city of Portland).
- A geotechnical site investigation program, including in-water and upland soil borings and cone penetration tests (CPTs) (as shown in Figure 4-4). Further details are provided in the FSP (Appendix A).
- A geotechnical laboratory testing program to evaluate the physical and engineering characteristics of the soils encountered during the site investigation. Geotechnical laboratory testing will be performed in accordance with current American Society for Testing Materials (ASTM) standards and is anticipated to include:
  - Moisture Content and Unit Weight (ASTM, 2019; ASTM, 2021);
  - Grain Size Distribution (ASTM, 2017e);
  - Grain Size – Percent Passing No. 200 Sieve (ASTM, 2017c);
  - Organic Content (ASTM, 2020a);
  - Specific Gravity (ASTM, 2014);
  - Hydrometer Analysis (ASTM, 2017f);
  - Atterberg Liquid and Plastic Limits (ASTM, 2017d);
  - Consolidated Undrained Triaxial Compression Test (ASTM, 2020b); and
  - One-Dimensional Consolidation (ASTM, 2020c).

Geotechnical site characterization field efforts are required to provide site soil properties suitable for use in a wide range of geotechnical analysis and RD. The work will be performed in accordance with applicable requirements specified in the ROD, ASAOC, *Remedial Design Guidelines and Considerations* document (EPA, 2021b), as well as other applicable guidance documents (e.g.,

Oregon Department of Transportation, Federal Highway Administration). In accordance with Oregon Water Resources Department requirements (Oregon Administrative Rule 690-240-0035), a Geotechnical Hole Report will be prepared for each geotechnical hole advanced for the project. The work will also require site access agreements from property owners, and short-term access agreement with Department of State Lands. Additionally, over-water work will likely require permits from USACE, U.S. Coast Guard, and/or the port authority or harbor master with jurisdiction over the study area.

#### 4.7 SHORELINE AND OVERWATER STRUCTURE INSPECTIONS

Data collection for shoreline and overwater structures will include multiple field inspections and owner/operator interviews. The work is intended to support evaluation of the current condition and use of each structure within the project area and confirm as-built details, including overall structure dimensions, member sizes and spacing, and construction materials. In addition, the owner/operator interviews will be used to determine current and future navigation needs for the waterway within the SIB Project Area. The data collection will fill data gaps identified in Section 3.7 and Table 3-4. The data collection will include the following field inspections:

1. Topside structure inspection of main structural system components, by foot.
2. Under-structure inspection of main structural system components, by boat.
3. A dive inspection using a minimum of a 3-member dive team for 10 working days. This includes a visual and tactile inspection of selected structures based on the screening level inspections.
4. A Mobile Terrestrial LiDAR Survey (MTLS), or boat-mounted laser scan survey, will be performed to locate and document the shoreline, in-water emergent debris, and nearshore marine structures.

Structure inspection data collection will be conducted in accordance with applicable requirements specified in the ROD, ASAOC, and *Waterfront Facilities Inspection and Assessment Manual of Practice No. 130* (American Society of Civil Engineers [ASCE], 2015). A screening level visual inspection of readily accessible main structural systems components and fender piles will be conducted to be able to form an engineering opinion on the general condition of each structure (see Section 4.11.1). The screening inspection results will identify those structures that are recommended to receive a dive inspection and to make further inspection recommendations.

Proposed shoreline extents for performing the MTLS are shown in Figure 4-5. Further details are provided in the FSP (Appendix A). During final engineering design, repair-level inspections will be needed for structures that require structural modifications because of anticipated impacts from the RA.

Shoreline and overwater structure inspections will not require specific permits. The work will require access agreements with property owners. The work does not rely on other data collection efforts or PDI studies.

#### **4.8 EXISTING UTILITIES AND DEBRIS IDENTIFICATION SURVEYS**

Field activities to generate data on utilities and debris potentially affecting RD will include a combination of sub-bottom profiling, side-scan sonar, and magnetometer surveys for detection of debris and existing buried utilities. This data collection will address the data gap identified in Section 3.8 and Table 3-5. Sub-bottom profiling (low-frequency sonar) will assist in both geological characterization as well as debris/utility detection. Magnetometer readings are intended for magnetic object and/or utility detection. Side-scan sonar will cover wider areas and is intended to capture debris in shallower water where multibeam cannot be effectively collected. Side-scan sonar is being proposed as a supplement to multibeam along the entire shoreline in areas where required due to the presence of higher-elevation marine debris (e.g., broken timber piles) or other obstacles preventing safe vessel access and data capture in the multi-beam survey. Proposed utilities and debris detection surveying locations are shown in Figure 4-6. Further details are provided in the FSP (Appendix A).

Stormwater outfalls will also be identified, including private outfalls for which insufficient data exist for RD. Field activities performed for characterizing both riverbank and existing upland utilities will locate remaining outfalls and discern their functionality. In addition, owner/operator interviews will be performed during the PDI to locate and evaluate as-built information and functionality of private outfalls so they can be considered, and used if needed, during RD.

Desktop studies will include a review for the presence of buried utilities (water, sewer, electrical, communications, pipelines, etc.), and evaluation of how waterfront activities and uses may affect those existing utility systems. Research will also be performed on utilities and debris to inform geotechnical site characterization field efforts (i.e., to avoid drilling conflicts with buried objects). Historical documents, aerial photos, and other sources of existing data will be reviewed. Locations of piles and other debris will be delineated from these sources for use in the RD.

Existing utilities and debris identification field efforts will be conducted in accordance with applicable requirements specified in the ROD and ASAOC, if applicable. This data collection will not require specific permits. Only outfall location efforts will require access agreements with property owners. Field efforts do not rely on other data collection efforts or PDI studies; however, the desktop study relies on owner/operator interviews and data collected in the field.

#### **4.9 HYDRODYNAMICS AND SEDIMENT DYNAMICS MEASUREMENTS**

Field measurement efforts are proposed to fill hydrodynamics and sediment dynamics data gaps identified in Section 3.9 and Table 3-6. This data is required to support site characterization; provide input data for numerical modeling efforts (CSM refinement, recontamination, cap stability, climate change impacts); validate the numerical model(s); and assist in PDI engineering studies. Bottom-deployed Acoustic Doppler Current Profilers (ADCPs) will be deployed at two stations, with co-located sensors measuring suspended sediment concentrations. Suspended sediment measurements are a low-cost way to determine the amount of suspended solids moving in the water column over time which supports recontamination evaluation and understanding of general sediment dynamics. Suspended sediments data collection includes laboratory analysis for conversion of measured turbidity to total suspended solids. A mid-deployment recovery and re-deployment will be performed to ensure data is properly captured. Vessel-mounted ADCP

(transect) surveys will also be performed to characterize larger-scale hydrodynamic patterns. These surveys will be performed during the deployment or recovery of bottom-mounted systems at multiple transects across the interior of the SIB and immediately outside the SIB in the main river.

High-frequency free surface elevation measurements will be collected to characterize vessel wakes and wind-waves using four pile-mounted sensors deployed at the same time as the bottom-mounted sensors. These measurements will allow evaluation of potential resuspension/scour and cap and riverbank stability. Bottom-mounted ADCP current data collection, suspended sediments data collection, and wave/wake data collection are assumed to last approximately 2 months, with a retrieval and re-deployment after the first month. Proposed locations of measurement activities for currents, water levels, wind-waves, and boat wakes are shown in Figure 4-7.

The outer bottom-deployed ADCP location was chosen to characterize currents closer to the entrance where river flows enter SIB and recirculate (Coast & Harbor Engineering, 2013). The inner bottom-deployed ADCP location was chosen to characterize currents in the more quiescent area within the SIB where velocities are typically less than 0.1 ft per second (Coast & Harbor Engineering, 2013). At both locations, consideration was made to avoid potential conflicts with vessel traffic, as well as bottom slope to ensure instrument package stability during the deployment.

SedFlume (sediment) cores are proposed to be collected in the field and analyzed in the laboratory to provide data regarding the erodibility of native sediments. Samples are proposed on a regular pattern throughout the SIB Project Area as shown in Figure 4-8. Further details are provided in the FSP (Appendix A).

This data collection will be conducted in accordance with applicable requirements specified in the ROD and ASAOC. Data collection with vessel-mounted and pile-mounted instruments will not require specific permits but pile-mounted measurements will require access agreements with property owners. Data collection with bottom-mounted instruments and SedFlume coring will require specific permits as well as access agreements with property owners. There are no precursors to any of the measurement activities related to hydrodynamics and sediment dynamics.

#### **4.10 HABITAT CONDITIONS SURVEY**

A targeted habitat conditions survey is needed to address data gaps identified in Section 3.11 related to characterization of aquatic and riparian habitat conditions within the SIB Project Area. Although some relevant data exists, it is proposed to conduct a field survey of the entire shoreline included within the SIB Project Area to document both bank conditions and substrate conditions within the shallow area defined as the area from 0 to -15 ft Columbia River Datum. The proposed survey would document present-day conditions around the shoreline and riverbanks and provide consistency in the quality and applicability of the data. It is noted that CWA Section 404 and 401 permits do not limit EPA's interpretation of substantive permit requirements and that future deliverables will incorporate Portland Harbor-specific examples as provided in the forthcoming Programmatic Biological Opinion.

The habitat survey will be performed in accordance with EPA’s National Rivers and Streams Assessment project non-wadeable field protocols for physical habitat characterizations (EPA, 2017b). Habitat data will be collected on transects spaced at 150-ft intervals along the shoreline using photo documentation of habitat conditions at a frequency sufficient to fully describe habitat conditions for input into the HEA. Data will be used to establish the acreages and conditions of each habitat area where remedial activities will occur. Habitat characterization will cover five zones as follows:

- Riparian area – areas above ordinary high water and less than 400 ft from the ACM.
- ACM – the area between ordinary high water and ordinary low water.
- Shallow water – the area between 0 to -15 ft Columbia River Datum.
- Deep water – the area deeper than -15 ft Columbia River Datum.
- Off-channel areas – tributaries to the main waterway.

The following data will be collected to characterize habitat conditions within each of these zones:

- Riparian area – vegetation, substrate, location with respect to historical floodplain, slope, presence of buildings, structures, and riprap.
- ACM – depth, substrate, presence of riprap, sheetpile/seawall, pilings, and suspended and floating structures.
- Shallow water – depth, substrate, presence of riprap, sheetpile/seawall, pilings, and suspended and floating structures.
- Deep water – depth, substrate, presence of riprap, sheetpile/seawall, pilings, and suspended floating structures.
- Off-channel areas – tributary water temperature and position relative to main channel substrate.

The habitat conditions survey will require access agreements for the portion of work conducted in the riparian zone on the riverbanks. The habitat conditions survey will incorporate information from the surface sediment sampling (Section 4.1), the riverbank conditions survey (Section 4.4), bathymetric and topographic surveys (Section 4.5), and the shoreline and overwater structure inspections (Section 4.7).

#### **4.11 ENGINEERING STUDIES**

Engineering studies are required to inform application of the technology application decision tree (Figure 1-3). Initial engineering studies are intended to identify critical impacts to structures, shorelines, the nearshore environment, and facility operations. Further detailed engineering analysis and design activities related to specific structures will also occur during the RD. This section describes the engineering studies considered to be required during the PDI. These studies are proposed to address data gaps identified in multiple subsections of Section 3.0, and to prepare for the RD. Studies will be conducted in accordance with applicable requirements specified in the

ROD, ASAOC, *Remedial Design Guidance and Considerations* document (EPA, 2021b), and *Waterfront Facilities Inspection and Assessment Manual of Practice No. 130* (ASCE, 2015).

#### **4.11.1 Structure Condition Assessments**

Screening-level condition assessments will be performed for each of the identified structures based on the results of field inspections in Section 4.7. Condition assessments are required information to support functional structure determinations according to the technology application decision tree (Figure 1-3). These assessments will identify major visually observable deficiencies that may affect the ability of the structures to carry future design loads and those most likely to be negatively impacted by the RA. Assessments will follow *Waterfront Facilities Inspection and Assessment Manual of Practice No. 130* (ASCE, 2015). The condition assessments will include an evaluation of the structure general condition, design loads, age and past repair history, geotechnical conditions, and likely capacity. Condition assessments themselves will not require specific permits or access agreements with property owners. This analysis relies on field inspection efforts described in Section 4.7.

#### **4.11.2 Facility Owner/Operator Interviews**

Owners and operators of waterfront facilities with structures will be interviewed for the following purposes:

- Improve understanding of site history,
- Obtain additional as-built data and repair history,
- Obtain past condition assessment reports,
- Determine current and future use requirements and anticipated design criteria, and
- Determine the current and future navigation depth requirements for the SIB Project Area.

These interviews are intended to supplement the field inspections described in Section 4.7 and to facilitate the functional structure evaluation. No known guidelines or requirements are applicable to this effort. Owner/operator interviews will not require specific access agreements but will require coordination with property owners. This effort does not rely on any other data collection efforts or PDI studies.

#### **4.11.3 Facility Future Use and RA Impact Evaluation**

Engineering evaluations will be performed to characterize the anticipated future use of the shoreline and overwater structures in the SIB and potential impacts of the RA. Structural analysis will be performed to evaluate capacities and capabilities to support design loads post-RA. RA impacts on shoreline and overwater structures will be evaluated with the following tasks:

- Estimate current structural system capacity based on condition assessment, as-built drawings, and past repair history;
- Perform a functional structures determination, including an estimate of the structures' remaining service life;

- Perform structural analysis using two dimensional finite element analysis (or similar) to determine impacts of RA on structural system capacity;
- Perform a more detailed (three dimensional [3D] finite element) analysis on a limited number of complex or sensitive structures either during the PDI or during the RD;
- Determine the relative decrease in structural system capacity compared to the as-built condition and relative to applicable building codes; and
- Modify the RD iteratively, where feasible, to avoid negative impacts to permanent, functional structures.

No known requirements are applicable to this effort. These studies will not require specific permits or access agreements with property owners. This effort relies upon the results of many field efforts and PDI studies, including bathymetric survey, utility and debris identification, geotechnical site characterization, slope stability and seismic evaluation, and riverbank characterization.

#### **4.11.4 Facility Operations and Construction Phasing Assessment**

Analysis will be performed to evaluate potential disruption to facility operations caused by the RA. Sequencing/planning schemes will be evaluated to identify impacts, identify both synergies and conflicts, develop conflict mitigation measures, and plan additional temporary operations scenarios, or other. Construction planning efforts will consider both existing and future use of facilities affected by RA on an annual and/or seasonal basis. This study does not address a specific data gap but represents an optimization effort to mitigate disruption impacts. Mitigation measures may consist of altering the proposed RA, altering the timing and/or sequencing of RA activities, or providing alternative operational scenarios for tenants. This study will be conducted in accordance with applicable requirements specified in the ROD, ASAOC, and *Remedial Design Guidelines and Considerations* document (EPA, 2021b). This study will not require specific permits or access agreements with property owners. This effort relies upon the results of many PDI studies, including application of the technology application decision tree (Figure 1-3) (which is also based on many other efforts), and the dredging study discussed in Section 4.11.5.

#### **4.11.5 Dredging Study**

A dredging study will be performed to evaluate critical elements of dredging in the SIB and streamline construction, and is anticipated to include the following elements:

- Anticipated equipment (mechanical, hydraulic, land-based vs. water-based, etc.);
- Equipment capabilities and limitations;
- Lateral and vertical extents of dredging;
- Over-dredging (construction tolerance) requirements;
- Site configuration considerations (sediments, bed slope, hydrodynamics, etc.);
- Geotechnical evaluation, for the purposes of evaluating potential dredging production rates, slope stability, side slope design, structural offsets, dewatering, and disposal considerations;

- Existing debris removal and existing structure considerations;
- Dredging production rates;
- Transloading, rehandling, and logistics for disposal; and
- BMPs and engineered recontamination control measures.

This study does not address a specific data gap but represents an optimization effort to reduce costs and environmental impacts during construction. This study will be conducted in accordance with applicable requirements specified in the ROD, ASAOC, and *Technical Guidelines for Environmental Dredging of Contaminated Sediments* (USACE, 2008). This study will not require specific permits or access agreements with property owners. This effort relies upon the results of many PDI studies, including application of the technology application decision tree (Figure 1-3) (which is also based on many other efforts).

#### **4.11.6 Constructability Assessment**

The purpose of the constructability assessment is to evaluate feasibility of implementing the proposed remediation concepts. Remediation concepts will be evaluated using field data collected during the PDI and the results of desktop engineering studies. Remediation concepts will likely consist of miscellaneous combinations of capping, dredging, dredging/capping, bank stabilization, habitat development, debris and non-functional structure removal, potential replacement of functional marine structures, and other elements to be determined. The assessment will be conducted by reviewing the construction process from start to finish and determining potential impacts of constructions on facility operations and whether proposed construction methods are likely to be practical and successful. Construction elements will include dredging, capping, demolition, bank stabilization, and rehabilitation or reconstruction of shoreline and overwater structures. The process is intended to:

- Integrate construction expertise into the planning and design process;
- Evaluate whether the RA concepts are buildable and maintainable;
- Provide insight into construction activities;
- Identify potential project construction risks;
- Reduce or prevent errors, delays, and cost overruns;
- Evaluate impacts to existing facilities;
- Evaluate traffic control (surface and maritime);
- Identify potential sources of aggregate materials (capping, shoreline protection, etc.);
- Evaluate anticipated site logistics and constraints, including utility conflicts within the work areas;
- Review potential environmental impacts for the proposed construction methods; and
- Establish general construction sequencing necessary to complete the project.

The constructability assessment will be conducted in coordination with the dredging study. The constructability assessment will also include a discussion on potential construction monitoring suitable to protect existing functional structures. This study does not address a specific data gap but represents an optimization effort to reduce overall risk and construction costs. This study will be conducted in accordance with applicable requirements specified in the ROD and ASAOC. This study will not require specific permits or access agreements with property owners. This effort relies upon the results of many PDI studies, including application of the technology application decision tree (Figure 1-3) (which is also based on many other efforts).

#### **4.11.7 Recontamination Potential Evaluation**

Sediment transport studies will be performed to evaluate recontamination potential in the SIB post-RA. Recontamination potential evaluations in this section include analysis of sediment movements which, when combined with contaminant concentrations from areas of sediment origin, provide input of contaminants from different sources for use in the SEDCAM modeling described in SAR Section 8.6. The hydrodynamic and sediment transport modeling results will be used to develop inputs for SEDCAM. SEDCAM will be applied to multiple locations spatially distributed within the SIB Project Area, and the hydrodynamic and sediment transport modeling results will inform key parameter values at each SEDCAM location. Those parameters will include local sediment deposition rates, scour rates, mixing depth, and COC loading. Recontamination will be considered from upland pathways, in-water pathways, and local pathways (e.g., local resuspension/scour). In addition, recontamination will be considered from both natural forces (e.g., river currents) and anthropogenic forces (e.g., propeller wash). The SAR (HGL, 2021a) determined that all the recontamination pathways discussed in this section are Status “C”, Uncontrolled, and require additional characterization and/or source control.

- Upland Pathways – Direct Discharges (Outfalls) Recontamination Potential: The purpose of this analysis is to evaluate the fate and relative contribution of contaminated sediments discharged to the SIB Project Area from outfalls. Existing numerical models of the SIB that include the river and outfall jets will be utilized, in combination with stormwater and hydrology information. Sediment footprints from simulated outfall discharges will be assigned contaminant concentrations based on contaminant concentrations measured during stormwater sampling. Work will consist of the following tasks:
  - o Hydrology evaluation – upland drainage and stormwater flows;
  - o Outfall discharge evaluations (flows, sediments, etc.);
  - o 3D hydrodynamic modeling of outfall discharges – extreme events;
  - o 3D hydrodynamic modeling of outfall discharges – typical conditions; and
  - o Generate sediment deposition footprint from simulated outfalls and rates of sediment deposition to be used as input to SEDCAM modeling for recontamination potential evaluation.
- Upland Pathways – Overwater Sources (Particulates) Recontamination Potential: The purpose of this analysis is to evaluate the fate and relative contribution of contaminated particulates (to be determined) discharged to the SIB Project Area from overwater activities. Existing hydrodynamic numerical models of the SIB will be utilized, in

combination with approximated behavior of overwater materials (to be determined). Data used to characterize over-water contributions will include any available measured concentrations within discharged particulates or estimates based on desktop study, and particulate physical properties relevant to in-water transport (density, diameter, and shape). Particulate material to be considered will include abrasive blasting material, paint chips, and solids components of stormwater runoff from over-water surfaces. Data sources may include existing stormwater monitoring data and published literature characterizing abrasive blasting material and marine paints. Transport and deposition will be simulated using hydrodynamic modeling combined with particle tracking (Lagrangian) or similar transport simulations. Work will consist of the following tasks:

- o Evaluate discharged material types (particulates, others), likely source locations, and contaminant concentrations;
  - o Perform 3D hydrodynamic modeling of hydrodynamics near over-water inputs;
  - o Simulate transport and deposition of over-water discharged particulates; and
  - o Characterize recontamination (dilution) from over-water sources.
- In-Water Pathways – River Sediment Transport Recontamination Potential: The purpose of this analysis is to evaluate the fate and relative contribution of contaminated sediments entering the SIB Project Area from other areas. Existing numerical models of the SIB that include the river will be utilized, in combination with river sediment information. Upstream river sediments will be incorporated into the modeling through sediment tracking analysis with multi-fraction sediment sources within the river upstream of the SIB. Work will consist of the following tasks:
    - o Redevelop existing mass-based river-wide model (coarsen);
    - o Re-validate coarse hydrodynamic model;
    - o Perform longer-term simulations – hydrodynamics (e.g., seasonal);
    - o Perform longer-term simulations – sediments (e.g., seasonal);
    - o Perform sediment tracking simulations from distinct river locations into the SIB;
    - o Perform sediment tracking simulations from distinct SIB locations into various remediation areas; and
    - o Characterize recontamination (dilution) from river source areas to the SIB.
  - Resuspension/Scour Pathways – Natural Forces: The purpose of this analysis is to evaluate the fate and relative contribution of contaminated sediments resuspended/scoured from un-remediated areas within the SIB Project Area. Existing natural hydrodynamics numerical models of the SIB will be utilized. Work will consist of the following tasks:
    - o Perform river conditions analysis - river flows, winds, outfall discharges;
    - o Evaluate wind-wave generation and transformation;
    - o Perform bathymetry change analysis;
    - o Incorporate SedFlume data into sediment transport model;

- o Perform 3D hydrodynamic (mass-based) model refinement;
- o Perform 3D hydrodynamic model calibration/validation using previously collected and newly collected data in the SIB;
- o Perform 3D hydrodynamic modeling of natural conditions – extreme events;
- o Perform 3D hydrodynamic modeling of natural conditions – typical conditions;
- o Perform climate change impact evaluation (temperatures, water levels, discharges);
- o Extrapolate 3D hydrodynamic modeling results to long-term conditions (sediment resuspension climate);
- o Map sediment resuspension zones;
- o Evaluate potential for natural scour based on erosion rate/duration; and
- o Perform natural forces scour calculations.
- Resuspension/Scour Pathways – Anthropogenic Forces from Vessels and Dry Docks: The purpose of this analysis is to evaluate the fate and relative contribution of contaminated sediments resuspended/scoured from un-remediated areas within the SIB Project Area, due to anthropogenic hydrodynamic forces. A suite of numerical models simulating these processes will be utilized. Work will consist of the following tasks:
  - o Purchase and process Automatic Information System (AIS) data;
  - o Analyze AIS data and select relevant vessel traffic;
  - o Evaluate ship positions, speeds, and power utilization;
  - o Compute propeller-wash bottom velocities;
  - o Perform conceptual fluid design modeling of drydock lowering/raising and related vessel movement;
  - o Estimate boat wakes (short-period Kelvin wakes) using empirical formulations;
  - o Perform boat wake transformation simulation using spectra in wind-wave model;
  - o Perform vessel hydrodynamic simulations for pressure field effects;
  - o Evaluate pressure field effects on sediment resuspension;
  - o Map sediment resuspension zones;
  - o Evaluate overlap of anthropogenic resuspension zones;
  - o Evaluate potential for anthropogenic scour depths based on erosion rate/duration; and
  - o Perform anthropogenic forces scour assessment.
- Resuspension/Scour Pathways – Sediment Releases During Dredging: The purpose of this analysis is to evaluate the fate and relative contribution of contaminated sediments resuspended during dredging. Existing river/SIB hydrodynamic numerical models will be utilized. Work will consist of the following tasks:

- o Analyze sediment characteristics from SedFlume results;
  - o Evaluate likely dredging equipment and methodology;
  - o Evaluate releases from both hydraulic and mechanical dredging, in coordination with the Dredging Study;
  - o Prepare dredging source inputs to 3D hydrodynamic model;
  - o Simulate sediment movements at various river flows;
  - o Map thickness/concentrations of materials spread during dredging;
  - o Analyze recontamination potential (dilution); and
  - o Evaluate benefits of various BMPs intended to limit resuspension and/or spreading.
- Future Climate Change Effects on Recontamination Potential: The purpose of this analysis is to evaluate the fate and relative contribution of contaminated sediments during future climate change conditions, for forces evaluated in other tasks (natural and anthropogenic). Previously constructed river and anthropogenic hydrodynamic numerical models will be utilized. Work will consist of the following tasks:
    - o Summarize potential changes in future conditions;
    - o Develop future conditions – natural conditions, outfall flows;
    - o Develop future conditions from changes in use – overwater sources, direct discharges, vessels/drydocks;
    - o Evaluate climate change impacts on groundwater recontamination; and
    - o Evaluate climate change impacts on riverbank erosion/slope stability.

These recontamination analyses address data gaps regarding potential for recontamination of the SIB post-RA from multiple sources. This study will be conducted in accordance with applicable requirements specified in the ROD, ASAOC, and *Remedial Design Guidelines and Considerations* (EPA, 2021b). This study will not require specific permits or access agreements with property owners. This effort relies upon the results of many field efforts and PDI studies.

#### **4.11.8 Cap Stability Evaluations**

Cap stability will be evaluated under both natural and anthropogenic erosive hydrodynamic forces, as well as slope stability, settlement, and seismic forces. The cap stability analyses are required to support application of the technology application decision tree (Figure 1-3) and overall RD. Analysis will include assessments for both post-RA conditions and future climate change (also post-RA) conditions. Future climate change conditions are anticipated to include increased rainfall and rainfall intensity, changes in temperatures and winds, and sea level change considering both eustatic sea level rise and local subsidence.

- Cap Stability Evaluation (Erosion) – Natural Conditions Post-Remedial Action: The purpose of this analysis is to evaluate stability of capping materials under natural erosive forces. Previously constructed river hydrodynamic numerical models will be updated for use in the analyses. Work will consist of the following tasks:

- o Incorporate capping materials (RD concept) into numerical models;
- o Perform 3D hydrodynamic modeling of natural conditions – extreme events;
- o Perform 3D hydrodynamic modeling of natural conditions – typical conditions; and
- o Evaluate cap mobility/stability under natural forces.
- Cap Stability Evaluation (Erosion) – Anthropogenic Conditions Post-Remedial Action: The purpose of this analysis is to evaluate stability of capping materials as part of RA alternatives evaluation, for anthropogenic conditions. Previously constructed anthropogenic hydrodynamic numerical models will be updated for use in the analysis. Work will consist of the following tasks:
  - o Evaluate new propeller-wash bottom velocities post-RA, and changes from pre-project conditions;
  - o Evaluate new pressure field (large vessel movement) bottom velocities post-RA, and changes from pre-project conditions;
  - o Evaluate post-RA maximum expected vessel-generated waves;
  - o Evaluate new drydock-induced bottom velocities post-RA, and changes from pre-project conditions; and
  - o Perform post-RA cap mobility and erosion assessment.
- Future Climate Change Effects on Cap Stability (Erosion): The purpose of this analysis is to evaluate stability of capping materials under future climate change scenarios for natural erosive forces. Previously constructed river hydrodynamic numerical models will be updated and utilized. Work will consist of the following tasks:
  - o Summarize updated projections by the Intergovernmental Panel on Climate Change and Climate Impacts Group at the University of Washington;
  - o Update future design conditions for flow rate from hydrologic projections developed by Climate Impacts Group for the selected emissions scenario corresponding to the remedy design condition (100-year storm);
  - o Update sea level rise projections based on the same emissions scenario considered for the hydrologic projections (obtained from either USACE or NOAA); and
  - o Evaluate climate change impacts on riverbank erosion/slope stability.
- Geotechnical Cap Stability: Geotechnical engineering analyses will be performed based on the results of the site characterization and support the following assessments:
  - o Evaluation of potential liquefaction susceptibility (Youd et. al., 2001; Boulanger and Idriss, 2014);
  - o Evaluation of static stability of moderately to steeply sloping ground by limit-equilibrium based slope stability analysis;
  - o Evaluation of seismic stability of non-liquefied, moderately to steeply sloping ground during earthquake-induced ground shaking events by limit-equilibrium based pseudo-static slope stability analysis;

- o Evaluation of bearing capacity failure mode and filter design, in general accordance with EPA’s Assessment and Remediation of Contaminated Sediments (ARCS) Program Guidance for In-Situ Subaqueous Capping of Contaminated Sediments (EPA, 1998);
- o Representative section development and identification of risks and failure modes;
- o Seismic stability analysis, per Section 5.2.5 of Remedial Design Guidelines and Considerations (EPA, 2021b);
- o Local subsidence evaluation based on existing data; and
- o Settlement analysis.

These cap stability analyses address the feasibility and longevity of the proposed RA. These studies will be conducted in accordance with applicable requirements specified in the ROD, ASAOC, *Remedial Design Guidance and Considerations* document (EPA, 2021b), and *Guidance for River Bank Characterizations and Evaluations at the Portland Harbor Superfund Site* (EPA, 2019b). These studies will not require specific permits or access agreements with property owners. These studies rely upon the results of many field efforts and other PDI studies.

#### **4.11.9 Green Remediation Practice Evaluation**

Green remediation practices will be evaluated according to Section 14.2.12 of the ROD for the initial RA concepts. The evaluation will consider the following construction elements:

- Use of renewable energy and energy conservation and efficiency approaches;
- Water conservation and efficiency approaches including water sense products;
- Use of cleaner fuels and reused or recycled materials;
- Limiting transportation, limiting idling of trucks/equipment, checking that vehicles are full prior to transport, and routing transport efficiently; and
- Implementing on-site BMPs (dust and noise control, reducing air pollutant and greenhouse gas emissions).

The green remediation practice evaluation will address ROD requirements related to construction, such as minimizing transportation of materials and using rail rather than truck transport to the extent practicable. During the design phase of the project, a Green Remediation Plan will be developed in accordance with the *Remedial Design Guidance and Considerations* document (EPA, 2021b). This analysis is proposed to reduce the environmental impact of construction activities. The Green Remediation Plan will include a discussion on how baseline versus reductions in energy and water usage, particulate emissions, waste generation and handling, and other improvements will be tracked and reported during construction. EPA Region 10 guidance to be considered will include the 11 primary elements listed in the EPA Region 10 Clean and Green Policy (EPA, 2009a), with a focus on reducing the anticipated environmental footprint of construction activities.

Per discussion with EPA on August 19, 2021, the green remediation practice evaluation will not need to include design investigations, and the Green Remediation Plan will be developed after the

PDI. The design team is committed to using BMPs during the design investigations to minimize their environmental footprint to the extent feasible. These studies will be conducted in accordance with applicable requirements specified in the ROD, ASAOC, *Clean and Green Policy* (EPA, 2009a), *Principles for Greener Cleanups* (EPA, 2009b), and the *Superfund Green Remediation Strategy* (EPA, 2010). These studies will not require specific permits or access agreements with property owners. This effort relies upon the results of many field efforts and other PDI studies.

#### **4.11.10 Flood Impact Evaluation**

Flood impact evaluation will be performed using a hydrodynamic model of the Willamette River and surrounding Columbia River. Modeling will be performed using HEC-RAS or other tools to be reviewed and approved by EPA (e.g., existing hydrodynamic models of the Willamette River system). The flood impact evaluation will include the following tasks:

- Incorporate a conservative RD concept (greatest potential to produce a net water level rise) into full river hydrodynamic model.
- Develop appropriate hydrologic inputs (Federal Emergency Management Agency 500-year data).
- Simulate a conservative set (maximum three) of extreme flood events.
- Evaluate uncertainties associated with potential climate change effects on future hydrologic conditions that affect the flood rise evaluation, using a modeling sensitivity analysis.
- Document changes in water levels in the river system.
- Generate Flood Impact Evaluation memo (draft and final).

The remedy will include activities at the mouth of the SIB that are close to the main river where changes to riverbed elevation may affect hydraulics. The proposed analysis will identify constraints on the RA in this area necessary to ensure no net rise in the 500-year floodplain elevation will be caused by RA. Post-remedy 500-year floodplain maps are not intended to be developed. The flood impact evaluation will be performed in accordance with Section 5.2.11 of *Remedial Design Guidance and Considerations* (EPA, 2021b). The evaluation will not require specific permits or access agreements with property owners. This effort relies upon the results of hydrodynamics and sediment dynamics field efforts, numerical model development as part of recontamination studies, and application of the technology application decision tree (Figure 1-3).

## 5.0 PDI MANAGEMENT PLAN

This PDI Work Plan proposes a plan to address data and analysis gaps by conducting field investigations and analyses needed to develop the BODR and RD Work Plan. This plan proposes a comprehensive multi-disciplinary field data collection program safely and efficiently using appropriate regulatory and industry-standard performance practices. EPA will approve fieldwork prior to implementation. At all times, this work will adhere to industry prescribed health and safety practices in the field and in the water. This also includes any current national, state, or local COVID-19 guidelines. The PDI will provide the information necessary to complete the SAR (HGL, 2021a) and develop the RD. The PDI will also include the information necessary to analyze the RD and demonstrate that the remedy will be effective and sustainable in the context of the SIB. Following implementation of the EPA-approved PDI, the Parties will submit a Draft PDI Evaluation Report for EPA comment and approval.

The Parties will follow the *Remedial Design Guidance and Considerations* document, which was developed consistent with the ROD to facilitate efficient and timely design work throughout PHSS. The *Remedial Design Guidance and Considerations* document was developed in coordination and collaboration with designers already performing RD at PHSS and the Portland Harbor Technical Coordinating Team. EPA will update the *Remedial Design Guidance and Considerations* document as needed through collaborative meetings and discussion with designers and the Portland Harbor Technical Coordinating Team. Section 1.4 of the *Remedial Design Guidance and Considerations* document provides clarification on determination of SMAs, how buried contamination is considered in design, where data replacement might be considered during design, technology assignment, equivalence analysis, and how PeCDD RALs will be addressed in design.

While the approved data, including baseline data will be considered, final decisions regarding RD activities including PDIs at the SIB Project Area, including delineation of SMAs, implementation of sampling necessary for design, and application of the ROD's technology matrix, will be made pursuant to the ASAOC and the scope of work incorporated therein.

### 5.1 SWAN ISLAND BASIN REMEDIAL DESIGN GROUP

The SIB RD Group consists of the following parties named in the ASAOC executed between the Parties (collectively known as the Respondents) and EPA effective January 20, 2021. The Respondents are:

- DTNA;
- Vigor;
- Cascade General, Inc.; and
- Shipyard Commerce Center LLC.

Additional Parties to the ASAOC are the Settling Federal Agencies, which consist of:

- Maritime Administration, U.S. Coast Guard;
- U.S. General Services Administration;
- Bonneville Power Administration; and
- U.S. Department of Defense.

Additional Settling Public Entities consist of:

- State of Oregon, acting by and through the Department of State Lands;
- City of Portland; and
- Port of Portland.

DTNA is represented by law firm Ogden Murphy Wallace P.L.L.C. from Seattle, Washington. Philip Spadaro of The Intelligence Group is the Respondents' project coordinator. The EPA Remedial Project Manager (RPM) is Madi Novak.

## **5.2 PROJECT ORGANIZATION CHART**

The project management team mirrors the project management team and structure identified for the overall RD and documented in the ASAOC and associated scope of work. Figure 5-1 illustrates HGL's management and reporting structure for the SIB Project Area including lines of communication with the clients, Project Coordinator Philip Spadaro, and EPA.

HGL Principal-In-Charge (PIC), Bob Overfelt, is responsible for contract performance, and he ensures that HGL meets its performance objectives and contractual requirements.

HGL Project Manager (PM) Jeff Hodge reports to Mr. Overfelt and is responsible for providing direction to the project staff and managing project activities including cost and schedule accountability. Mr. Hodge provides a point of contact for the clients, project coordinator, subcontractors, and suppliers. Primary roles and responsibilities of the PM include coordinating with the PIC and technical director to select project staff and assign responsibilities; communicating with the clients and project coordinator; developing, monitoring, and complying with project budgets, schedules, and deliverables; coordinating technical efforts; anticipating and managing changed conditions; and implementing project QC and health and safety procedures.

HGL Technical Director Shane Cherry reports to the PIC and is responsible for providing technical direction to the project staff. Mr. Cherry communicates with the clients, project coordinator, subcontractors, and suppliers, as necessary. Other responsibilities of the technical director include reviewing deliverables and directing technical efforts.

Mott MacDonald is a subcontractor to HGL, providing multi-disciplinary engineering analysis and design services. Mott MacDonald's responsibilities in the PDI include oversight of field sampling for engineering-related data; and coastal, hydraulic, geotechnical, civil, and structural engineering studies to support future RD.

Pacific Groundwater Group is a subcontractor to HGL, providing sediment chemical characterization including data gaps analysis and supporting SEDCAM modeling to evaluate recontamination. Pacific Groundwater Group is also responsible for data management as well as database statistics and maintenance.

The Bridgewater Group is a subcontractor to HGL specializing in environmental site assessments and multi-media investigations including upland source control investigations, RD, implementation oversight, permitting, environmental management, and compliance assistance.

*This page was intentionally left blank.*

## **6.0 DELIVERABLES/SCHEDULE**

The PDI will be documented in the PDI Evaluation Report as specified in the ASAOC, Appendix A “Remedial Design Statement of Work.” The ASAOC specifies that the PDI Evaluation Report must include:

1. Summary of the investigations performed;
2. Summary of investigation results;
3. Summary of validated data (i.e., tables and graphics);
4. Data validation reports and laboratory data reports;
5. Narrative interpretation of data and results;
6. Results of statistical and modeling analyses, if applicable;
7. Photographs documenting the work conducted; and
8. Conclusions and recommendations on whether the data is sufficient to complete the BODR.

Appendix A “Remedial Design Statement of Work” in the ASAOC (Section 6.2 “Schedule”) specifies that the deadline for the Draft PDI Evaluation Report is “As set forth in the approved PDI Work Plan.” This PDI Work Plan proposes June 26, 2023, as the deliverable date for the Draft PDI Evaluation Report. The rationale for that proposed date is summarized below as an overview of the timeline for completing sequentially dependent data collection efforts and analyses proposed in this PDI Work Plan.

The period for conducting the field data collection begins with EPA approval of this PDI Work Plan anticipated late Fall 2021. The proposed schedule for the work is shown in Table 6-1. Certain sampling efforts, such as stormwater event sampling that target winter season rainfall events, would benefit from EPA approval in time to allow mobilization by late 2021. Most other field efforts are seasonal or weather dependent, and the bulk of the PDI field data collection effort is planned to occur between April and August 2022. Field sample collection feeds into laboratory analysis followed by data validation and reporting. Field sampling efforts will be staggered to account for required test durations or capacity limitations at certain process steps. For example, geotechnical sampling will occur as early as possible to allow up to 3 months for sample analysis. The proposed delivery date of June 26, 2023, for the Draft PDI Evaluation Report allows for field sampling to occur through August 2022 and provides enough time for the subsequent steps of analysis, validation, reporting, and review.

The work elements proposed in this PDI Work Plan fall into three categories:

- Field sample collection and laboratory analysis,
- Field surveys and other field measurements/observations, and
- Engineering analysis studies.

HGL proposes to report on all components of the proposed PDI in the draft PDI Evaluation Report. Where appropriate, engineering analysis reporting will be expanded upon within the BODR. HGL believes it is necessary and constructive to describe the engineering studies while planning the PDI to transparently present and discuss with EPA the anticipated application of the field data to the RD as early as possible. The overall schedule for the RD will be optimized by beginning to develop the BODR concurrently with PDI performance and reporting. The specific work elements proposed as part of this PDI Work Plan are summarized below.

## **6.1 FIELD DATA COLLECTION ELEMENTS OF THE PDI**

The field data collection elements of the PDI are summarized in the following list. These PDI elements include field sample collection and laboratory analysis, field surveys, and other field measurements/observations. HGL proposes to report all these results in the Draft PDI Evaluation Report to be delivered to EPA on June 26, 2023.

1. Surface and subsurface sediment contaminant concentrations
2. Porewater upwelling area survey
3. Stormwater outfall and conveyance system sampling
4. Riverbank characterization survey
5. Bathymetry and topographic surveys
6. Geotechnical sampling
7. Shoreline and overwater structure inspections
8. Existing utilities and debris identification surveys
9. Hydrodynamics and sediment dynamics field measurements
10. Habitat conditions survey results

## **6.2 ENGINEERING STUDY ELEMENTS OF THE PDI**

The engineering study elements of the PDI are summarized in the following list. These PDI elements include engineering analysis that relies on a combination of existing data and new data that will be collected as part of the PDI. HGL proposes to report the results of engineering studies in the Draft PDI Evaluation Report to be delivered to EPA on June 26, 2023. This is not a fully inclusive list of all engineering evaluations required for RD. Additional engineering evaluations will be identified and documented in the Basis of Design Report, the RD Work Plan, and subsequent design submittals.

1. Shoreline and overwater structure condition assessments
2. Facility owner/operator interviews
3. Facility future use and RA impact evaluation
4. Facility operations and construction phasing assessment
5. Dredging study
6. Constructability assessment
7. Recontamination potential evaluation
8. Cap stability evaluations
9. Green remediation practice evaluation
10. Flood impact evaluation

Notes:

For sample locations with Total PCBs results calculated from both congeners and aroclors, the concentration associated with congeners is shown here.

Sample duplicates are included with a unique Sample ID and a shared Map Station ID.

Dataset includes sediment samples within 200 feet of the SIB Project Area boundary.

Data Sources:

**Table 3-7  
Data Gap Analysis – Hydrodynamics and Sediment Dynamics  
Pre-Design Investigation Work Plan; Swan Island Basin Project Area, Portland, Oregon**

Data Requirement	Existing Data Summary	Data Gap to be Filled
Currents and water levels	<ul style="list-style-type: none"> <li>• Acoustic Doppler Current Profiler (ADCP) transect-based current velocity data near Dry Dock 6 (Stillwater Sciences, 2014). Data has short duration and minimal coverage.</li> <li>• ADCP transect-based current velocity data in the main river (David Evans Associates [DEA], 2002-2004). This data does not cover the Swan Island Basis (SIB) Project Area.</li> <li>• National Oceanic and Atmospheric Administration (NOAA) and United States Geological Survey (USGS) provide freely available hydrologic data (flows and water levels) at various locations on the river.</li> </ul>	<ul style="list-style-type: none"> <li>• Current and water level measurements will be collected at multiple locations over 2 months using bottom-mounted instruments.</li> <li>• Current and water level measurements will be collected along transects by boat throughout the project site during deployment or recovery of bottom-mounted sensors.</li> <li>• Utilize DEA wider river velocity measurements taken from 2002 to 2004 for validating numerical models. No upstream/downstream river velocity data gap has been identified.</li> <li>• Numerical modeling results will be generated using a river-wide 3D hydrodynamic model.</li> </ul>
Winds	<ul style="list-style-type: none"> <li>• Long-term measurements (1976-2021) are available at Portland International Airport from the National Climatic Data Center. Historical measurements (1961-1990) are also available from Meteorological Resource Center (See details in U.S. Environmental Protection Agency [EPA], 2016).</li> <li>• Extremal analysis of winds was performed for the Remedial Investigation (RI)/Feasibility Study (FS) (EPA, 2016).</li> </ul>	<ul style="list-style-type: none"> <li>• No data gap has been identified.</li> </ul>
Climate change	<ul style="list-style-type: none"> <li>• Guidance documents from EPA and others, including Climate Change Adaptation Technical Fact Sheet: Contaminated Sediment Remedies (EPA, 2015), and Adaptation Strategies for Resilient Cleanup Remedies (2017).</li> </ul>	<ul style="list-style-type: none"> <li>• Literature review to determine potential changes in precipitation, temperatures, winds, and other factors potentially affecting the flood rise evaluation and future cap and riverbank stability.</li> </ul>
Wind-waves and boat wakes	<ul style="list-style-type: none"> <li>• No measurements are available.</li> <li>• No wind-wave modeling results or boat wake estimates are available inside the SIB.</li> </ul>	<ul style="list-style-type: none"> <li>• Wind-wave and boat wake measurements will be collected at multiple locations over 2 months using pile-mounted sensors. Sensors will record high-frequency, free-surface elevations to be later analyzed to characterize wind-waves and boat wakes.</li> </ul>
Sediment dynamics	<ul style="list-style-type: none"> <li>• RI/FS (EPA, 2016) and pre-Remedial Design sediment investigation give grain size and specific gravity at multiple locations.</li> <li>• RI/FS (EPA, 2016) included a river-wide 2006 SedFlume campaign with two relevant samples with significant variability, and age of the previous sampling is a concern (&gt;15 years). New SedFlume data is required.</li> <li>• Total suspended solids measurements from November 2005 to April 2006 are available at multiple locations between river mile (RM) 2 and RM 21 (WEST Consultants, Inc., 2006). The data was collected over a range of flows and over a tidal cycle. However, no measurements inside the basin are available.</li> <li>• Short-duration sediment release modeling results are available from evaluation of impacts during maintenance dredging (ERM-West, Inc., 2014). This data may be instructive to dredging studies.</li> </ul>	<ul style="list-style-type: none"> <li>• SedFlume data (cores and laboratory analysis) will be collected around the project site in accordance with details in the Field Sampling Plan.</li> <li>• Suspended sediment measurements will be taken at multiple locations over 2months using bottom-mounted instruments, to be co-located with ADCPs.</li> <li>• Numerical modeling results will be generated using a river-wide 2D hydrodynamic model, with local 3D hydrodynamic modeling performed on a limited basis as needed.</li> <li>• Short-duration sediment release modeling results for past maintenance dredging (ERM-West, Inc., 2014) will be used to assist dredging release studies.</li> <li>• No sediment release modeling data gap has been identified.</li> </ul>
Propeller wash	<ul style="list-style-type: none"> <li>• No measurements or modeling results are available.</li> <li>• EPA guidance, including Guidance for Subaqueous Dredged Material Capping (Palermo et al., 1998).</li> </ul>	<ul style="list-style-type: none"> <li>• Empirical analysis of vessel particulars and movements.</li> <li>• Vessel particulars to be obtained from Automatic Information System data.</li> <li>• Conceptual fluid design (CFD) modeling of propeller wash based on vessel traffic evaluation.</li> </ul>
Vessel positions, both recent (satellite data) and historical (other data)	<ul style="list-style-type: none"> <li>• Freely available data (Bureau of Ocean Energy Management [BOEM] and NOAA, 2019) for download and processing.</li> <li>• Data from January 2021 to present requires purchase.</li> <li>• Historical data not presently available.</li> </ul>	<ul style="list-style-type: none"> <li>• Download freely available data.</li> <li>• Purchase recent data.</li> <li>• Owner/operator interviews to obtain historical data.</li> </ul>
Dry dock operations and hydrodynamics	<ul style="list-style-type: none"> <li>• No information on operations or dry dock particulars is presently available.</li> <li>• No modeling results are presently available.</li> </ul>	<ul style="list-style-type: none"> <li>• Dry dock information (drawings, design reports).</li> <li>• Typical operations - raising and lowering protocols and tracking vessel movements.</li> <li>• CFD modeling of dry dock and vessel movements.</li> </ul>

**Table 4-1  
Summary of Data Gaps and Proposed Data Collection  
Pre-Design Investigation Work Plan; Swan Island Basin Project Area, Portland, Oregon**

Data/Analysis Type	Data Gaps	Proposed Data Collection
Surface Sediment Contaminant Concentrations	<ul style="list-style-type: none"> <li>• Minor gaps in spatial coverage to characterize horizontal extent of contamination within Sediment Management Area (SMA).</li> <li>• Data needed to support analysis of short-term water quality effects during dredging activities.</li> <li>• Data needed to delineate areas for technology applications including enhanced natural recovery (ENR), dredging, and capping.</li> <li>• Physical and chemical characterization in areas under docks and other structures.</li> </ul>	<ul style="list-style-type: none"> <li>• 29 "step out" surface samples to refine delineation of SMA boundary (4 surface grabs, 25 samples collected from 0 to 1-foot interval of selected cores). One additional surface grab sample targeting historical PAH outlier for a total of 30 surface sediment samples.</li> <li>• 3 bulk sediment samples to support dredge elutriate testing (DRET).</li> </ul>
Subsurface Sediment Contaminant Concentrations	<p>Insufficient core data to characterize vertical extent of contamination within SMA.</p>	<ul style="list-style-type: none"> <li>• 171 cores to 10-foot depth (including 2 archived cores), 10 cores to 20-foot depth</li> <li>• Core locations are based on a 150-foot grid for coverage</li> <li>• 10-foot cores are sampled at 1-foot intervals from 1- to 6-foot depth (total 845 samples), and core intervals 6- to 10-ft depth are archived. 20-foot cores are samples at 1-foot intervals from 1- to 15-foot depth (total 140 samples), and core intervals 15- to 20-ft depth are archived.</li> </ul>
Sediment Pore Water Characterization	<p>No available data to map upward porewater migration within areas of potential sediment capping. Data needed to identify and delineate areas where sediment capping would be potentially feasible, to design sediment caps and evaluate sediment cap effectiveness.</p>	<p>Transect survey using vessel mounted or towed instrument for thermal profiling at sediment/water interface within SMA</p>
Riverbank Characterization	<p>Riverbanks within Swan Island Basin (SIB) Project Area not adequately characterized to assess source control sufficiency and inform stabilization as part of Remedial Design (RD).</p>	<ul style="list-style-type: none"> <li>• Visual survey of physical bank conditions to evaluate erosion potential and delineate areas of potentially erodible sediments.</li> <li>• Coordinate with geotechnical sampling program to evaluate geotechnical failure potential and characterize soil conditions (e.g., grain size, soil erodibility).</li> </ul>

**Table 4-1 (Continued)**  
**Summary of Data Gaps and Proposed Data Collection**  
**Pre-Design Investigation Work Plan; Swan Island Basin Project Area, Portland, Oregon**

Data/Analysis Type	Data Gaps	Proposed Data Collection
Stormwater Discharge	Lack of adequate data on recontamination potential chemical (RPC) loading from municipal and private outfalls to determine source control sufficiency and complete the source control sufficiency assessment.	<ul style="list-style-type: none"> <li>• Inventory of the current status of discharges from private outfalls RPC exceedances in sediments.</li> <li>• Conduct high-volume, flow-weighted sampling to support RPC load calculations at five municipal stormwater (SW) outfalls.</li> <li>• Collect SW grab samples and SW solids samples using in-line traps at 12 locations.</li> <li>• Conduct reconnaissance of 7 private outfalls to determine if additional sampling is necessary.</li> </ul>
Bathymetric and Topographic Surveys	Complete recent multi-beam survey of the Swan Island Basin (SIB) Project Area for use in analysis and RD. New bathymetry will address data gaps related to technology application decisions and provide essential model geometry information for hydrodynamic and sediment transport modeling to address sufficiency assessment data gaps related to recontamination analysis.	Site-wide multibeam bathymetric survey with complete coverage
Geotechnical Sampling	Site stratigraphy and geotechnical design parameters.	<ul style="list-style-type: none"> <li>• Historical geological and geotechnical records and survey maps.</li> <li>• New program of in-water borings, upland borings, cone penetration tests (CPTs), and groundwater elevation observations.</li> <li>• Total of 31 borings and 15 CPTs</li> </ul>
Shoreline and Overwater Structures Inspections	Structural information required to make a functional structures determination and evaluate Remedial Action (RA) impacts on existing structures, and overwater activities to determine recontamination.	<ul style="list-style-type: none"> <li>• Structural information for all potentially affected shoreline and over-water structures.</li> <li>• Mobile Terrestrial LiDAR Survey</li> <li>• Land-based and water-based inspections</li> <li>• Owner/operator interviews to evaluate activities and future use</li> <li>• Owner/operator interviews to determine current and future navigation requirements and identify future maintenance dredge areas</li> </ul>
Existing Utilities and Debris Identification	Locations and elevations of existing utilities and marine debris affecting RA.	<ul style="list-style-type: none"> <li>• Sub-bottom profile survey along transects</li> <li>• Magnetometer survey along transects</li> <li>• Side-scan sonar with complete coverage</li> </ul>

**Table 4-1 (Continued)**  
**Summary of Data Gaps and Proposed Data Collection**  
**Pre-Design Investigation Work Plan; Swan Island Basin Project Area, Portland, Oregon**

Data/Analysis Type	Data Gaps	Proposed Data Collection
Hydrodynamics and Sediment Dynamics Measurements	Hydrodynamic/transport processes for conceptual site model refinement, data for model validation, and data for direct use in RD. Data supports hydrodynamic and sediment transport modeling to address source control sufficiency assessment by evaluating recontamination potential for multiple pathways.	Measurement of: <ul style="list-style-type: none"> <li>• Currents from vessel-mounted instruments</li> <li>• Currents from bottom-mounted instruments</li> <li>• Suspended sediments, wind-waves, and boat wakes</li> <li>• Sediment erodibility (SedFlume cores) at 30 locations</li> </ul>
Flood Impact Evaluation	Understanding of potential RA impacts on 500-year flood elevations	Flood impact modeling to evaluate potential net rise due to RA
Habitat Conditions Survey	Aquatic and terrestrial habitat conditions in shallow nearshore zone and on riverbanks not adequately documented to support analysis of RD impacts to aquatic resources within waters of the U.S. Habitat data are needed to inform a Habitat Equivalency Analysis (HEA) that will be used by EPA for decision making regarding compliance with Clean Water Act and Endangered Species Act.	<ul style="list-style-type: none"> <li>• Conduct a habitat conditions survey to document habitat conditions within the SIB project area.</li> <li>• Coordinate habitat survey with riverbank characterization for efficiency based on overlapping information needs.</li> </ul>
Sufficiency Assessment Report (SAR) - Source Control Status	HGL assigned source control sufficiency status of “B” (conditionally controlled) to three upland source areas and “C” (uncontrolled) to 15 upland sources summarized on SAR Table 4-1.	<ul style="list-style-type: none"> <li>• Stormwater monitoring and sampling program described in PDI Work Plan Section 4.3</li> </ul>
SAR – Riverbanks	<ul style="list-style-type: none"> <li>• Existing riverbank conditions (e.g., vegetation, armoring, evidence of erosion, erodibility assessment, and potential for overland flow to the river) based on visual assessment survey.</li> <li>• Geotechnical evaluation to assess potential for bank slope failure.</li> <li>• Chemical characterization of riverbank soils in locations subject to bank erosion or instability.</li> </ul>	<ul style="list-style-type: none"> <li>• Riverbank characterization survey described in PDIWP Section 4.4</li> </ul>

**Table 4-1 (Continued)**  
**Summary of Data Gaps and Proposed Data Collection**  
**Pre-Design Investigation Work Plan; Swan Island Basin Project Area, Portland, Oregon**

Data/Analysis Type	Data Gaps	Proposed Data Collection
SAR Direct Discharges	<ul style="list-style-type: none"> <li>• Status (active, inactive, removed) of private outfalls adjacent to SMAs.</li> <li>• Lack of current SIB RPC stormwater data at city outfalls M-1, M-2, M-3, S-1, and S-2 for evaluating RPCs using proposed SEDCAM modeling.</li> <li>• Lack of current SIB RPC stormwater data at USCG MSU and Port SIUF OU3 to assess the sufficiency of conveyance system cleanings with CUL or RAL exceedances in sediment.</li> <li>• Lack of SIB RPC stormwater data from outfalls near CUL or RAL exceedances in sediment (Port of Portland Dredge Base, ATC Leasing Co LLC, Barge Eagle Inc, North Basin Watumull, and DTNA Corp-5 Wind Tunnel).</li> <li>• Possible off-site tracking of PCB-impacted soil from an upland site in the M-3 outfall basin and entrainment in road runoff to the city’s conveyance system.</li> </ul>	<ul style="list-style-type: none"> <li>• Stormwater monitoring and sampling program described in PDI Work Plan Section 4.3</li> <li>• Riverbank characterization survey described in PDIWP Section 4.4</li> </ul>

**Footnotes:**  
a) In-line sediment trap deployment and collection of manual solids samples are not proposed at this location due to historical and likely future river backflow. If proposed field reconnaissance during high tide indicates that a sediment trap can be installed above the highest river elevation, then a sediment trap will be installed at this location with the inlet above the highest river elevation. The proposed HVS monitoring and solids sampling location may be adjusted to AAM104 where river backflow is less likely (i.e., pipe invert elevation of 13.01 feet MBDC versus 6.58 feet MBDC at AAM107).  
b) While manhole AAQ003 is closer to OFM-3, its pipe invert elevation is less than the river elevation range during the wet season (3.11 feet versus 4 to 10 feet MBDC). As a result, the proposed monitoring location was adjusted.

**Acronyms**

- BES = Bureau of Environmental Services
- COC = contaminant of concern
- COP = City of Portland
- ft = feet
- HVS = high-volume, time-weighted sample
- ID = identification
- ILS = in-line solids (confined space entry)
- MBDC = Morrison Bridge Datum Conversion. The City of Portland datum is converted to Morrison Bridge Datum (USGS gaging station 14211720, gage height of 1.55 feet above National Geodetic Vertical Datum of 1929) by subtracting 2.92  
<https://www.portlandoregon.gov/transportation/article/70676>
- MSG = manual solids grab (confined space entry)
- NA = not applicable
- ROD = Record of Decision for Portland Harbor Superfund Site (EPA, 2017 and 2020)
- SWC = flow-weighted, composite stormwater sample collected using Teledyne ISCO 6712C autosamplers equipped with flow meter
- TOC = total organic carbon
- TSS = total suspended solids
- USCG = U.S. Coast Guard
- VIS = visual system inspection

AAP951 Manhole	River Flow Direction
Tax Lot Boundary	

**Proposed Sampling Methods**

SWG Stormwater Grab	ILS In-Line Solids
HVS In-Line Solids and Stormwater	MSG Manual Solids Grab

Symbols repeated for sampling of multiple laterals at indicated manhole

**Outfalls**

Active	Inactive	Abandoned	Unknown
Active - City of Portland Municipal Outfalls (M-1, M-2, M-3, S-1 and S-2)			
Inactive - Former Non-Contact Cooling Water Discharge Points (WR-436 through WR-439)			

Notes:

EPA - U.S. Environmental Protection Agency  
 HVS - High Volume Sampling  
 NOAA - National Oceanic and Atmospheric Administration  
 RI/FS - Remedial Investigation/Feasibility Study  
 ROD - Record of Decision  
 USACE - U.S. Army Corps of Engineers

(1) The high volume sampling system methodology includes pumping stormwater at a consistent rate over the duration of the storm and running high volumes of water through the HVS system to distinguish between the dissolved and solids fractions and obtain ROD Cleanup Levels for focused contaminants of concern.

(2) The in-line sediment trap design is similar to that utilized in the EPA-approved Round 3A Stormwater Field Sampling Plan, Portland Harbor RI/FS (LWG, 2007). If possible, one trap will be installed in each lateral.

(3) Manual stormwater solid grab samples will be collected at time of manhole entry if a minimum of 8-oz of solids are present in manhole/lateral. If less than 8-oz of solids are present, then the manual grab sample locations shall be abandoned and alternative upstream locations will be inspected and selected.

(4) Stormwater grab samples will be collected using ISCO auto-samplers.

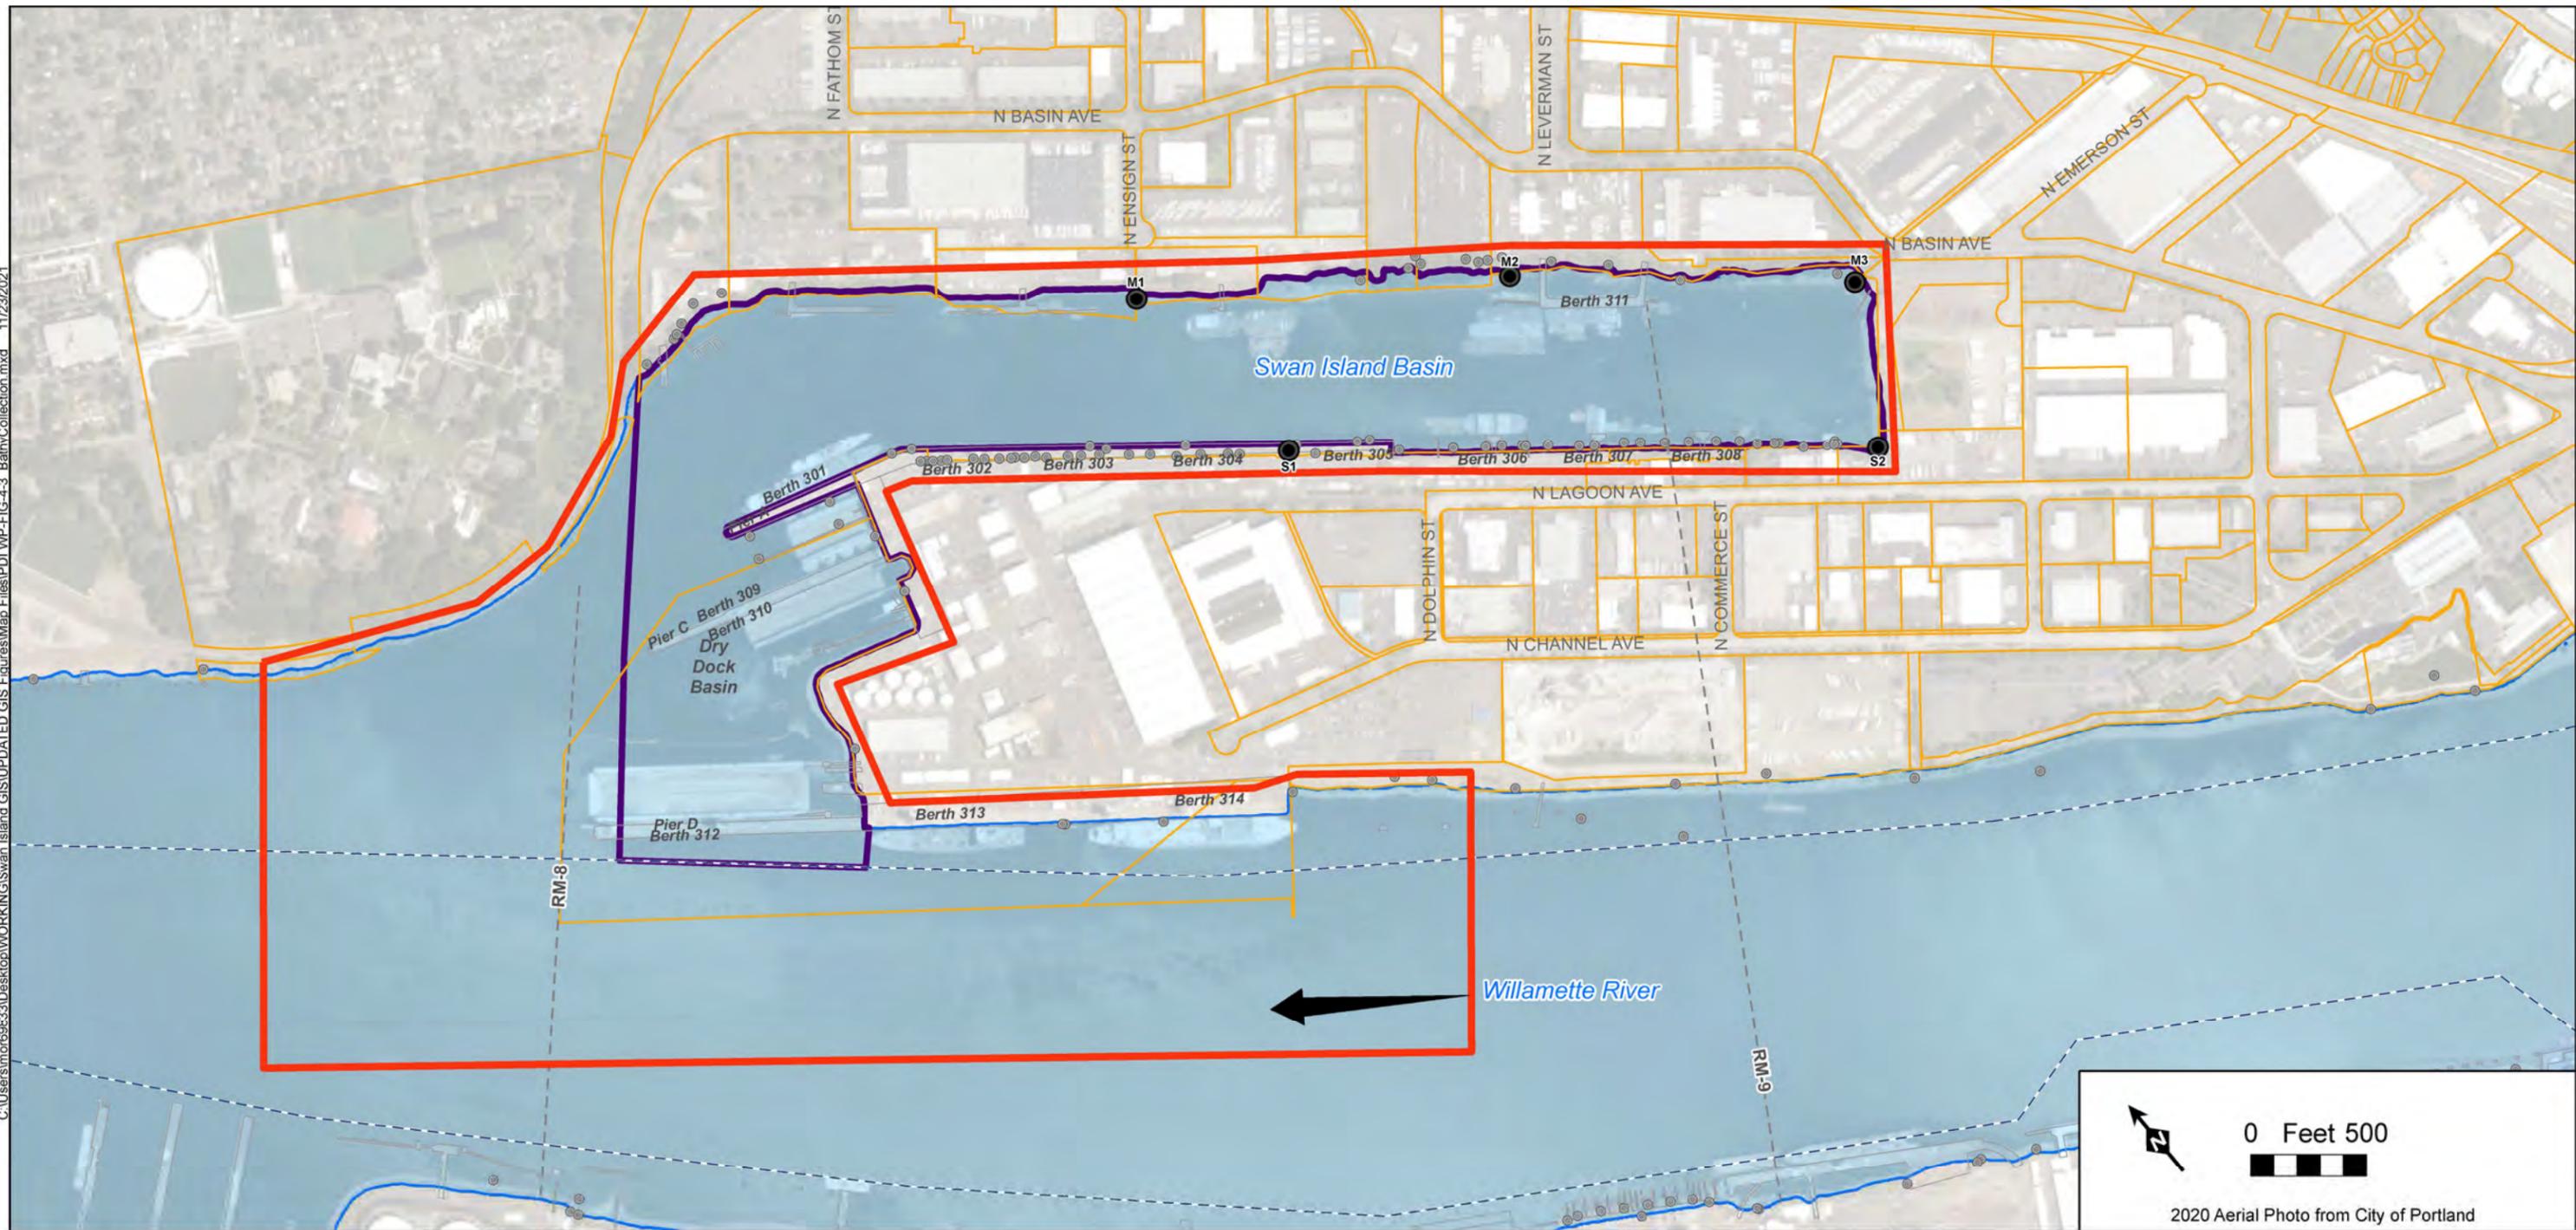

(5) Where visual outfall inspections reveal the presence of solids, a single composite manual grab sample will be collected from all outfalls on the property.

**FIELD SAMPLING PLAN  
SWAN ISLAND BASIN PROJECT AREA  
PORTLAND HARBOR SUPERFUND SITE  
PORTLAND, MULTNOMAH COUNTY, OREGON**

## **1.0 INTRODUCTION**

On December 1, 2000, the Portland Harbor Superfund Site (PHSS) was listed on the National Priorities List due mainly to concerns about contamination in the sediments and the potential risks to human health and the environment from consuming fish. The most widespread contaminants found at PHSS include polychlorinated biphenyls (PCBs), polycyclic aromatic hydrocarbons (PAHs), and dioxins/furans.

In January 2017, the U.S. Environmental Protection Agency (EPA) issued a Record of Decision (ROD) that presents the selected remedy for the in-river portion of PHSS contamination. The selected remedy was chosen in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), and to the extent practicable, the National Contingency Plan.

On January 14, 2021, certain Parties<sup>1</sup> and EPA voluntarily entered into an *Administrative Settlement Agreement and Order on Consent (ASAOC)* (EPA, 2021), to perform Remedial Design (RD) work within the Swan Island Basin (SIB) Project Area of PHSS. Figure 1-1 shows the SIB Project Area and vicinity.

This *Field Sampling Plan* (FSP) serves as Appendix A to the *SIB Draft Pre-Design Investigation Work Plan* (HydroGeoLogic, Inc. [HGL], 2021a). The Pre-Design Investigation (PDI) Work Plan provides background information on the project, identifies the data gaps to be filled, and summarizes the data and information gathering tasks that will be conducted during the PDI to fill these data gaps.

This FSP supports and guides the PDI sampling within the SIB Project Area and the SIB Upland Area and provides details for field sampling locations and procedures for the planned PDI project tasks. In addition to this FSP, other PDI planning documents that are being submitted concurrently include the following:

- *Draft Uniform Federal Policy-Quality Assurance Project Plan* (HGL, 2021b), Appendix B of the PDI Work Plan: Provides quality control (QC) elements to satisfy the data quality objectives for each task specified in the PDI Work Plan. The protocols established in the Uniform Federal Policy (UFP)-Quality Assurance Project Plan (QAPP) are necessary to

---

<sup>1</sup> Parties to the Administrative Settlement Agreement and Order on Consent (ASAOC) are EPA and Daimler Trucks North America LLC, Vigor Industrial LLC, Cascade General, Inc., and Shipyard Commerce Center LLC (collectively, Respondent(s)); Maritime Administration, U.S. Coast Guard, U.S. General Services Administration, Bonneville Power Administration, and U.S. Department of Defense (collectively, Settling Federal Agencies); and the state of Oregon, acting by and through the Department of State Lands, the city of Portland, and the Port of Portland (collectively, Settling Public Entities).

ensure the data generated is of a sufficient quality to support development of valid conclusions.

- *Draft Health and Safety Plan* (HGL, 2021c), Appendix C of the PDI Work Plan: Identifies and describes physical, chemical, and biological hazards relevant to each planned field task, and provides hazard mitigation techniques to address these hazards.
- *Draft Emergency Response Plan* (HGL, 2021d), Appendix D of the PDI Work Plan: The Emergency Response Plan (ERP) will be used in the event of an accident or emergency during performance of the RD work.

Portions of this FSP were derived from the Surface and Subsurface Sediment Field Sampling Plan for Swan Island Lagoon, Portland Harbor Superfund Site from Pacific Groundwater Group (PGG) (PGG, 2018).

## **1.1 PROJECT SETTING**

The SIB Project Area (SIB Site) is the active cleanup area designated in the ROD between approximately river mile (RM) 8.1 and RM 9.2 on the northeast side of the Willamette River (Figure 1-1). The SIB Project Area is approximately 1.1 miles in length, 117 acres in size, and includes riverbanks from top of the bank to the river. The upland area adjacent to the SIB Site, which discharges to the SIB includes approximately 588 acres of mostly impervious area with primarily light industrial uses (Figure 1-2). Stormwater discharges from the upland area to the SIB from five city outfall basins (M-1, M-2, M-3, S-1, and S-2), six Port of Portland outfalls, as well as multiple private outfalls. Potentially contaminated riverbanks are present in the SIB Project Area as well as impacted surface and subsurface sediment.

## **1.2 BACKGROUND**

The historical and present-day description of the SIB Site provides relevant context for understanding the physical work environment for sample and data collection that will be guided by this FSP. The Willamette River is the 19th largest river in the United States and is one of 14 American Heritage Rivers in the country. The Willamette River flows into the larger Columbia River, which eventually flows into the Pacific Ocean. Even though the Willamette River is nearly 100 RMs from the Pacific, there are tidal influences within the SIB project area and overall, it is a large and dynamic river. During its 309-mile course, which ends at its confluence with the Columbia River, it drains 11.7 percent (%) of the area in the state of Oregon.

In 1891, the Oregon State Legislature created the Port of Portland. Since the late 1800s, the Portland Harbor section of the Lower Willamette River has been extensively modified to accommodate a vigorous shipping industry. Modifications include redirection and channelization of the main river; draining seasonal and permanent wetlands in the lower floodplain; and relatively frequent dredging to maintain the navigation channel, access to docks, and wharf facilities. Constructed structures, such as wharfs, piers, floating docks, and pilings, are especially common in Portland Harbor where urbanization and industrialization are most prevalent. These structures largely accommodate or support shipping traffic within the river and stabilize the riverbanks for urban development. Riprap is the most common bank-stabilization method although upland

bulkheads and rubble piles are also used. Seawalls help control periodic flooding as most of the original wetlands bordering the river in the Portland Harbor area have been filled.

Historically, contaminants from many facilities entered the river system from different activities including, but not limited to ship building and repair; ship dismantling; wood treatment and lumber milling; storage of bulk fuels; manufactured gas production; chemical manufacturing and storage; metal recycling, production, and fabrication; steel mills, smelters, and foundries; and electrical production and distribution. These activities have resulted in direct discharges from upland areas through stormwater and wastewater outfalls; releases and spills from commercial operations occurring over the water; municipal combined sewer overflows; and indirect discharges through overland flow, bank erosion, groundwater, and other nonpoint sources. In addition, contaminants from off-site sources have reached the SIB project area through surface water and sediment transport from upstream and through atmospheric deposition. Operations that continue today along the riverbanks include bulk fuel storage, barge building, ship repair, automobile scrapping, recycling, steel manufacturing, cement manufacturing, operation and repair of electrical transformers (including electrical substations), and many smaller industrial operations.

A federal navigation channel, with an authorized depth of -40 feet (ft) Columbia River Datum<sup>2</sup> (CRD), extends from the confluence of the Lower Willamette River with the Columbia River to RM 11.6. Container and other commercial vessels regularly transit the river. Certain parts of the river require periodic maintenance dredging to keep the navigation channel at its authorized depth. In addition, the Port of Portland and other private entities periodically perform maintenance dredging to support access to dock and wharf facilities. Dredging activity has greatly altered the physical and ecological environment of the river in Portland Harbor. The current navigation depth was authorized in 1962 and dredging work on the authorized 40-ft-deep channel from Portland and Vancouver to the Pacific was completed in 1976. In 1999, Congress authorized the Willamette River to be deepened to 43 ft; however, this has not yet occurred. Swan Island Lagoon was created in the 1930s when dredge spoils were used to fill in part of the channel and connect Swan Island to the mainland. The Willamette River channel, from the Broadway Bridge (RM 11.6) to the mouth (RM 0), varies in width from 600 to 1,900 ft. The U.S. Army Corps of Engineers (USACE) maintains the navigation channel.

Development of the river has resulted in major modifications to the ecological function of the Lower Willamette River. However, several species of invertebrates, fish, birds, amphibians, and mammals, including some protected by the Endangered Species Act, use habitats that occur within and along the river. The river is also an important pathway for migration of anadromous fish such as salmon and lamprey. Various recreational fisheries, including salmon, bass, sturgeon, crayfish, and others, use the Lower Willamette River. Resident fish in the site include but are not limited to smallmouth bass, brown bullhead, black crappie, and carp.

---

<sup>2</sup> CRD is used as the nautical chart datum for the Lower Willamette River. CRD is a reference plane that USACE established in 1912 by observing low water elevations at various points along the Columbia and Willamette rivers (USACE, 1966). Consequently, CRD is not a fixed/level datum but slopes upward as one moves upstream. River users can obtain the depth on a chart and apply tide or river-level gauge readings, relative to CRD, to compute actual water depth. Low water values are used for navigation charting to provide conservative depth values in the event accurate tide data is not available to the river user.

### **1.3 PURPOSE AND OBJECTIVES**

This FSP describes the sampling methodologies and strategies that will be employed to achieve the objectives of the PDI, outlined in the PDI Work Plan. Information presented in this FSP includes field methods, sample handling, management of investigation-derived wastes, and an overview of the analytical programs associated with the different components of the PDI. The five principal data gap objectives of the PDI are summarized below.

1. Define the specific needs required to fully inform the design development and evaluation based on a conceptual design approach and strategy consistent with the ROD.
2. Define the specific needs to support the ASAOC applications required for Sediment Management Area (SMA) refinement, conceptual site model refinement, and effective use of the technology application decision tree shown in the PDI (Figure 1-3). As such, PDI surface sediment sampling will be completed to refine the lateral extent of contaminants of concern (COCs).
3. Compile and evaluate existing available data and analysis relevant to the defined data and analysis needs as determined by the design and required applications.
4. Identify data gaps by comparing what is needed to what is available.
5. Develop a work plan to guide the collection of new data and the completion of new analyses to address the data gaps.

In this FSP, “SMA” describes SIB Project Area sediments for which Remedial Action Levels (RALs) and/or principal threat waste (PTW) thresholds were exceeded and where a remedial technology of dredging or capping was assigned in the PHSS ROD (Figure 1-3) (EPA, 2017a).

## **2.0 DATA GAP SUMMARY**

The purpose of this FSP is to describe the data and information collection activities that will be used to support the PDI and ultimately the Basis of Design Report (BODR). The PDI Work Plan developed three data gap tasks: preliminary SMA delineation, conceptual site model refinement, and application of ROD technology application decision tree. See Section 3.0 of the PDI Work Plan for a detailed discussion on the types of data considered for use on this project. Section 4.0 of the PDI Work Plan provides a detailed overview of the PDI approach.

A summary of the data gap categories identified in the PDI Work Plan is provided below and summarized in more detail on Table 2-1:

1. Surface and Subsurface Sediment Contaminant Concentrations
2. Riverbank Characterization
3. Geotechnical Site Characterization
4. Sediment Porewater Characterization
5. Stormwater Outfall and Conveyance System Sampling
6. Bathymetry and Topography
7. Shoreline and Overwater Structures and Activities
8. Hydrodynamics and Sediment Dynamics Measurements
9. Existing Utilities and Debris Identification
10. Flood Impact Evaluation
11. Habitat Conditions Survey

In support of these data gaps, the following field data collection activities will be performed:

- Sediment surface and subsurface sampling;
- SedFlume analysis core sampling;
- Dredge elutriate sampling;
- Riverbank data sample collection;
- Geotechnical boring and cone penetration testing;
- Stormwater, stormwater solids, and in-line sediment trap sampling; and
- Habitat conditions survey.

The following surveys will be conducted, and additional data will be collected for an engineering analysis:

- Shoreline inspection and structural condition survey;
- Multi-beam bathymetric survey data;
- sub-bottom, magnetometer, and side-scan sonar data;
- mobile terrestrial light detection and ranging (LiDAR) survey (MTLS) data (laser scan);
- current, water level, wind-wave, and boat wake data; and,
- transect survey for thermal profiling at sediment/water interface.

The COCs and their respective cleanup levels (CULs) are listed in Table 2-2 of this FSP (EPA, 2020a).

*This page was intentionally left blank.*

### **3.0 PROJECT ORGANIZATION AND FIELD TEAM**

Key project staff and their titles and responsibilities are provided in the RD team organizational chart in Worksheets #3 and #5 in the UFP-QAPP. The SIB Project Coordinator will notify the EPA Project Coordinator no less than 14 days before sample collection activities as required by the ASAOC statement of work Section 5.6 (d)(5) so that EPA can schedule planned oversight. The HGL project manager (PM) shall not make field adjustments without first obtaining EPA approval of deviations in the field through field change requests.

#### **3.1 TEAM ORGANIZATION AND RESPONSIBILITIES**

Team organization is detailed in the UFP-QAPP, see Worksheets #3 and #5 *Project Organization and QAPP Distribution*. HGL is coordinating activities for this FSP including management of subcontractors, field sampling, analysis, and reporting scoping tasks. HGL PM Jeff Hodge, will be responsible for overall project coordination and providing oversight on project deliverables.

Subcontractors for marine vessel support, analytical laboratory processing, and data validation will be arranged prior to fieldwork.

#### **3.2 COMMUNICATION AND INFORMATION FLOW**

The communication pathways strategy is outlined in Worksheet #6 of the UFP-QAPP. The field team leader (FTL) will be the point of contact for field staff during the implementation of this FSP. Deviations from this FSP or the UFP-QAPP will be reported to the PM and the Client Management Team and regulatory agencies for consultation.

#### **3.3 FSP PREPARATION AND CONTENT**

This FSP has been prepared in accordance with the following EPA decision and guidance documents.

- Guidance for Conducting Remedial Investigations and Feasibility Studies, EPA/540/G-89/004 (EPA, 1988).
- PHSS ROD for Portland Oregon (EPA, 2017a).
- Sampling Plan for Pre-RD, Baseline and Long-Term Monitoring (EPA, 2017b).
- Program Data Management Plan, Portland Harbor RD Investigation PHSS (EPA, 2018).
- Administrative Settlement and Order on Consent (AOC) for RD at Willamette Cove Project Area (EPA and WC Group, 2019).

## **4.0 FIELD AND SAMPLING ACTIVITIES**

The field activities described in this section flow from the data gap evaluations sampling design that has been developed based on the results of previous site investigations. Sediment-related field sampling activities are surficial grab sampling, subsurface coring, and sediment erodibility sampling. Additional field activities include riverbank evaluation and riverbank soil sample collection; geotechnical investigation; surface water monitoring; and stormwater, stormwater solids, and in-line sediment trap sampling. Refer to Table 4-1 for a summary of field activities and associated proposed samples and analyses.

Field sampling activities will be conducted under the Health and Safety Plan (HASP) and performed in accordance with the standard operating procedures (SOPs) included in Appendix A of this FSP. SOPs were selected from previous Portland Harbor reports and five SOP libraries maintained respectively by HGL, EPA, Pacific Groundwater Group (PGG), Mott Macdonald (MM), and Bridgewater Group (Bridgewater). Standardized forms to be used for recording field data and documentation are included in Appendix B of this FSP. Individual SOPs also include field forms to be used.

Information on chain of custody (CoC), packaging, and shipping samples is in Worksheets #26 and #27 of the UFP-QAPP. Hard copies of these documents will be provided to the project team.

### **4.1 UTILITY LOCATES**

Before any intrusive activity at the SIB begins, steps will be taken to determine if the area contains underground utilities or subsurface debris, even though utilities and/or debris may have been previously located. Known underground utilities are presented in the National Oceanic and Atmospheric Administration (NOAA) Willamette River chart for the SIB (NOAA, 2019). Intrusive activities are defined as any activity that produces a manmade cut, cavity, hole, or trench, in the ground surface or sediment surface as a result of soil/sediment removal or any activity that results in an object placed into the earth below the surface. These activities include excavating, drilling, auguring, boring, shoveling, fence post driving, driving stakes, etc.

Prior to initiating intrusive fieldwork, within or adjacent to the SIB, the presence of subsurface utilities and debris will be evaluated in accordance with SOP 411.03 (Appendix A). NOAA navigation charts for the SIB Project Area will be reviewed to denote areas where abandoned cables are located. A site reconnaissance will be performed to identify and review site health and safety issues, locate proposed exploration locations, and identify other logistical issues. A minimum of 2 full business days, but not more than 10 full business days prior to beginning the subsurface investigation, each proposed on-land boring location will be marked for utility clearance through the Oregon Utility Notification Center (dial 811 or submit online at <https://digsafelyoregon.com/resources/locate-requests/>) and in accordance with SOP 411.03 (Appendix A). Exploration locations within the SIB (in-water locations) will be marked with a direction and offset from the closest adjacent high-bank location, and the specific location communicated to the Oregon Utility Notification Center through global positioning system (GPS) coordinates.

## **4.2 SEDIMENT SAMPLING**

The following sections describe the procedures and methods to be followed in collecting the surface and subsurface sediment samples. The historical surface and subsurface sediment sampling stations within the SIB Site are presented in Figure 4-1. Instructions on sampling procedures, recordkeeping, sample handling, storage and shipping, and field QC procedures are in Section 4.7 of this FSP. See Table 4-1 for a summary of sediment sample types, numbers, and analyses. A discussion of the relevant sample containers, analytes, preservation, and holding times requirements can be found in Worksheets #19 and 30 of the UFP-QAPP.

Surface sediment is defined as sediment within the top 1 ft (or 30 centimeters [cm]), and subsurface sediment is defined as sediment lower than 1 ft (or 30 cm) below mudline. A total of 186 locations will be sampled, including 5 surface grab sample locations and 181 subsurface coring locations. At 25 of the subsurface core locations, samples will be collected from the 0 to 1-ft interval to characterize surface contamination, for a total of 30 surface-sediment samples. The sediment sampling locations were selected to: a) update the spatial extent (horizontal and vertical) of contamination around the ROD-selected remedy (Alternative F Modified); b) refine the SMA footprint and technology assignments in the SIB; and c) delineate the extent of PTW. The sampling and analysis results will also support the evaluation of remedy effectiveness after implementation. Samples will be tested for focused COC analytes, including Total PCBs, Total PAHs, DDx, 2,3,7,8-TCDD, 1,2,3,7,8-PeCDD, 2,3,4,7,8-PeCDF, 2,3,7,8-TCDF, 1,2,3,4,7,8-HxCDF, and Total cPAHs (BaP Eq)<sup>3</sup>.

Additional surface and subsurface samples will be collected from depth intervals within the 181 sediment cores to be frozen and archived for potential future analysis to aid RD efforts. Refer to Sections 4.2.2 and 4.2.3 for the full description of the sediment collection procedures and sediment samples to be collected. Procedures for positioning and sample location are discussed Section 7.0 and in SOP A-7 Horizontal and Vertical Control (Appendix A).

### **4.2.1 Sampling Vessels and Equipment**

The marine vessel subcontractor will operate the vessel and perform the surface and subsurface sediment sampling activities. The subcontractor will utilize one sampling vessel, equipped with hydraulic power grab sampler and Vibratory Core Tube Driver (vibracore) to complete the work. The vessel that is anticipated for use has a virtual anchoring system that incorporates an autopilot and two small motors to keep the vessel on station without needing to set fixed anchors. The vessel will target proposed locations, record actual GPS sampling coordinates, and export a coordinate file electronically. In addition, field personnel will record the coordinates on field data sheets. The vessel will be mobilized from the city of Portland public boat ramp at N. Basin Avenue or the Marine Consortium (Fred Devine Diving and Salvage) dock near the N. Ensigh Street cul-de-sac.

The hydraulic power grab sampler will target penetration depths of 30 cm (0 to 1 ft) and will be retrieved on deck. A medium-sized power grab, designed and manufactured by the vessel

---

<sup>3</sup> Two constituents (naphthalene and chlorobenzene) not listed on the PHSS COC list are listed as additional PTW constituents. Chlorobenzene was not detected in surface or subsurface sediment samples from the SIB Project Area, and is not considered further in this FSP. Naphthalene will be analyzed along with other PAHs.

subcontractor, will be used for this project. The medium-sized power grab will have a recovery volume of about 0.05 to 0.08 cubic yards for acceptable grabs. Samples will be collected on the vessel and stored on ice until transferred to the analytical laboratory. At each sample collection location, a GPS will be used to position the vessel at a fixed sampling station. As stated in the PDI Work Plan, final coordinates will be reported after fieldwork is complete.

Vibracore tubes will be advanced up to 10 ft. A minimum of 4-inch-diameter Lexan, aluminum, or stainless core tubes and custom core catchers will be used for core collection. New polycarbonate liners may be used in the interior of the core tubes to help core recovery and processing.

Equipment and supplies will include equipment for positioning, sampling, sample processing, recording, and shipping samples. The analytical laboratory will supply sample containers and preservatives, as well as coolers and packing material.

#### **4.2.2 Surface Sediment Sample Collection Procedures**

Surface sediment sample types and sampling depth intervals are consistent and comparable with protocols from previous investigations so that the datasets are comparable (EPA, 2016a; EPA, 2016b).

A total of 29 surface sediment samples will be collected according to a grid-pattern sample design. One additional sample from grid cell C37 will be collected as a targeted resample of a total PAHs outlier result from 2002 associated with the Station ID: WLCOFJ02M0304M3040. There will be a combined 30 surface sediment samples. These locations include five hydraulic grab samples and the top 30.48 cm (1 ft) from 25 core (subsurface sampling) locations that were identified as data gaps (see PDI Work Plan Sections 3.0 and 4.0). The grids are shown on Figure 4-2. Table 4-2 summarizes the sampling approach. Figure 4-3 shows proposed surface sediment sample stations within the SIB Site. At subsurface core locations where the 0- to 1 ft interval is not needed for surface sample analyses, the 0- to 1-ft interval will be frozen and archived.

In locations where a core is collected but a surface sample is not needed to meet 150-ft spacing criteria, the top interval of cores will be archived. Some of these may be necessary to fill in COC-specific data gaps. These potential data gaps include:

- Grid cells D2 and F35 for tributyltin (TBT);
- Grid cells C3, K3, and L4 for diesel, pesticides, and TBT;
- Grid cells O7 and B26 for pesticides;
- Grid cell B28 and C28 for dioxin/furans;
- Grid cell B29 for metals, diesel, and TBT; and
- Grid cells B34 and B35 for diesel and TBT.

These potential sample analyses, and others that come up as appropriate, will be analyzed from archived material on a case-by-case basis as an additional phase of analysis. Analysis of archived surface samples will be performed, as necessary, to meet 150-ft spacing criteria along the SMA

boundary for each specific COC. EPA may be consulted for review on the necessity of analyzing archived material in some cases.

#### **4.2.2.1 Grab Sampling**

In general, sample collection will be performed as described in SOP 403.08 (Appendix A). This section includes grab sampling procedures, a target recovery and relocation plan, and information on surface sample collection and compositing.

##### *4.2.2.1.1 Power-Grab Sampling*

Surface sediment grab samples will be collected with a hydraulic power grab sampler. The hydraulic power grab sampler will target collection of sediment from the upper 0 to 30 cm of sediment at each sample location (without adjusting vessel position). Power grab samples will consist of a three-point composite sample like manual grab locations. Based upon field determination, samples that do not meet each of the following criterion will not be accepted (acceptance criteria) (PSEP, 1996; Integral, 2004):

1. No or minimal excess water leaking from the jaws of the sampler.
2. No excessive turbidity in the overlying water of the sampler.
3. Sampler did not over-penetrate.
4. Sediment surface appears to be intact with minimal disturbance.
5. Program-specific penetration (20 cm) has been achieved.

For this sampling, the acceptance penetration depth for grab samples is 20 cm, as was used in previous studies. A minimum of three consecutive casts of the grab sampler will be attempted at each location, while trying to achieve the 20-cm penetration depth. Additional attempts may be made based on professional judgement of the FTL. If a 20-cm penetration depth cannot be obtained, the sample of the greatest depth will be retained. If field conditions preclude the field staff from collecting proposed target samples (e.g., limited access, poor recovery, safety concerns, debris/rock/bedrock causing refusal), then the FTL will adjust or abandon the location and record the reason in the field logbook. All information related to failed attempts will be documented and reported with the other field notes. If an adjusted sample location falls outside of a 25-ft radius of the planned sample location, or if a sample location is abandoned, the location will be documented in a field change request for EPA approval. Section 8.1.1 of this FSP describes the procedure for requesting EPA approval.

After grab sample acceptance, sediments will be collected from the hydraulic power grab using a stainless-steel spoon, avoiding sediments in contact with the sides of the sampler. Organisms larger than 1 cm and pieces of debris will be removed and noted in the sample log sheet. Large organisms will be returned to the SIB. The sediment will be placed in a large, stainless-steel bowl and homogenized. Once the volume of sediment from each grab has been homogenized to a uniform consistency and color, sediments will be visually described and recorded on field logs or sample description forms (Appendix B). The following information will be recorded: sediment texture; sediment color; presence, type, and strength of odors; grab penetration depth (nearest cm), degree of leakage, or sediment surface disturbance; and obvious abnormalities such as wood/shell fragments or large organisms. Sediments will be placed in the appropriate laboratory-provided

sampling containers and stored in a cooler at 4 degrees Celsius (°C) until transport to the laboratory.

#### *4.2.2.1.2 Manual-Grab Sampling*

Due to access limitations or low water levels exposing shallow sediments, it may be necessary to collect surface sediment samples using manual sampling equipment (i.e., shovels, hand augers) appropriate to the field conditions encountered at the time of sampling. Similar to the power-grab samplers, the manual-grab target sample interval will be from 0 to 30 cm in depth, with a minimum penetration depth of 20 cm. Three manual-grab samples will be collected at each location within 25 ft of the core station centroid for compositing as described in Section 4.2.2.2. Coordinates for every manual grab station will be read on a handheld GPS and recorded in the field notes or tablet.

#### *4.2.2.1.3 Surface Sediment Target Recovery and Relocation Plan*

Grab samples not meeting the target criteria outlined in Section 4.2.2.1.1 will be rejected and the sample collection steps repeated until the acceptance criteria are met; however, no more than nine individual grab attempts will occur at each sample station (i.e., no more than three attempts at each grab location). In areas in which sediment conditions do not allow penetration of 20 cm below mud line after three grab attempts, the field staff will document the attempts and move to the next grab composite location. Subsample locations may be adjusted based on unexpected field conditions (e.g., presence of riprap, logs, large debris, or other obstructions). A manual probe may be used to evaluate the sediment quality (i.e., hardness, presence of obstructions, and other factors) in the general vicinity of rejected surface sample locations, to identify a suitable offset location. Deployment attempts will be repeated within an approximate 10-ft radius of the target subsample location. If two of the three composite grabs are successful, the surface sample will be considered a successful sample. If material is recovered from only one of the three composite grab locations, following consultation with the HGL PM, FTL, and EPA, the target coordinates at the unsuccessfully sampled station may be updated or the single grab may be accepted. Grab samples, regardless of acceptance, will be logged as they are collected, and accepted subsamples will be processed as described in Section 4.2.3.1.2. Any unused sample volume will be disposed of offsite as investigation derived waste.

#### **4.2.2.2 Surface Sample Collection and Compositing**

Approximately 1 liter (L) of sediments will be collected from each surface grab location and transferred to a stainless-steel bowl for mixing to homogenize the samples as detailed in SOP 403.03 (Appendix A). Sediments that are in contact with the sides of the sampling device will be avoided when collecting the minimum volume for homogenization. Large rocks, organisms, and pieces of debris will be avoided during collection or removed during homogenization and noted in the sample description form. The transfer container and mixing bowl will be rinsed but not decontaminated between grab sample composite locations. Prior to mixing, the following physical characteristics of the grab samples will be described and recorded on a sample description form using the American Society of Testing Materials (ASTM) D2488 visual soil classification procedure (ASTM, 2017). This procedure includes describing sediment texture; sediment color; presence, type, and strength of odors or petroleum sheens; grab penetration depth (to the nearest cm); and obvious features or characteristics, such as wood, shell fragments, or biological activity.

The maximum depth of evidence of biological activity will be noted at each sample location. After the sample is thoroughly mixed, the required amounts will be transferred to the appropriate sampling containers. Worksheets #19 and #30 in the UFP-QAPP list the analysis to be performed (see solid matrix), sample preservation appropriate to the analytical method, the analytical extraction and holding time, and the type and volume of containers required per sample/analysis. After thoroughly wiping down the sample container threads, the container lid will be sealed, wrapped in bubble wrap, and the wrapped container sealed in a plastic bag, then stored on ice in a sample cooler. This will prevent leakage and potential cross-contamination.

### **4.2.3 Subsurface Sediment Sampling**

Subsurface sediment core samples will be collected at 181 selected locations as shown in Figure 4-4. These locations were identified using a 150-ft grid based on core density for PHSS RDs (EPA, 2021), RM 9W, Willamette Cover, and effective spacing in Terminal 4. The grid is shown on Figure 4-2. Collection of sediment cores and the various drilling methods that can be used for their collection are discussed below.

Proposed subsurface core location identifications (IDs), proposed grid cell IDs, mudline elevations, core depths, and target sample intervals for the cells are presented in Table 4-3. Core location and sample IDs will correspond with the surface sediment station ID; therefore, the core station IDs will not be numerically sequential.

#### **4.2.3.1 Sediment Core Collection**

Subsurface sediment core samples will be collected with a target penetration depth of 10 ft below mud line. Total core tube length is 15 ft. Subsurface samples will be collected at 1-ft intervals from each core. Ten of the core locations will be collected with a target penetration depth of 20 ft using 20-ft core tube lengths to help constrain depth of RAL and PTW exceedances. These ten deeper core samples will be collected from grid cells N0, J8, E18, C19, E20, E22, E27, E33, D35, and F35. Two cores, collected from grid cells H0 and I0, will be archived and analyzed depending on any identified RAL and PTW threshold exceedances in neighboring cells H1 and I1.

Analyses will be performed on the 1-ft sample intervals from 1 ft below mud line to 6 ft below mud line. Sample intervals below 6 ft depths will be frozen and archived for possible future analyses. Analysis of archived subsurface sediment will most likely be triggered by the need to constrain the depth of contamination with two consecutive 1-ft intervals below the deepest CUL exceedance after the first phase of sample results are received. It may not be necessary to perform analysis on every core to constrain depth of contamination, and EPA will be consulted on any reductions to the analysis of archived samples. Additional archived material may be analyzed as necessary, and in consultation with EPA, as needed, to support RD. For example, an anonymously high COC result may warrant analysis of nearby (horizontally and vertically) archived material.

Table 4-3 presents the location, sample IDs, core depths, and analyses for these samples. Subsurface core sample collection will be performed as described in SOP 403.07 (Appendix A). In general, coring will follow these steps:

- Core tube caps will be removed immediately prior to placement into coring device to minimize potential core contamination.
- Position will be recorded when the vibracore first rests on the sediment surface.
- The vibracore will be advanced without power (under its own weight), then vibration will be applied until the core tube is advanced to the target depth (10 or 20 ft) or refusal.
- After a brief pause, the core tube will be extracted from the sediment using only the minimum vibratory power needed for extraction.
- As soon as the core tube daylight to the surface water/air interface, a bottom cap will be placed over the tube to prevent material loss out of the core catcher.
- The exterior side walls of core tube will be inspected for signs of potential nonaqueous phase liquid (NAPL) and scrapes/scoring of the tube walls from contact with dense gravel/debris. If NAPL is suspected, then the field staff will take appropriate field precautions, as described in SOP A-1 Hydrocarbon Field Screening (Appendix A).
- The following core collection data will be recorded in the core collection log that can be found in Appendix B.
  - Date/Time. Local date and time of initial use of the vibracore at each station.
  - Depth to Mudline. Water depth at the sampling station at the time of core collection.
  - Total Drive Length. Core tube length and depth of the core tube penetration into the subsurface.
  - Recovered Length. Thickness of the sediment column retained in the core tube prior to sectioning and removal of the core catcher.
  - Sediment Observation. Grain size, color, notable odors, debris, etc. observed at each of the cut ends of the core section.
- Samples designated for freezing and archiving at the analytical laboratory will be documented as appropriate on the CoC, in accordance with the UFP-QAPP.

#### *4.2.3.1.1 Core Acceptance Criteria and Contingency Plans*

Core will be accepted, rejected, or stored on the vessel pending another drive attempt. Each subsurface sediment core will be retrieved on deck and accepted if each of the following acceptance criterion is met:

- Overlying water is present and the surface is intact.
- Core has 80% recovery versus penetration, which is consistent with other sites in Portland Harbor.
- Core tube is in good condition (not excessively bent).
- Minimum penetration depth has been achieved (within +/- 2 ft of target).

Note that the field staff will achieve 80% sample recovery using various methodologies. Sample attempts will be made within the 25-ft radius tolerance. For deviations outside the 25-ft tolerance,

EPA will be notified by a method accessible to the field crew while on site (e.g., mobile phone followed up with an email). If EPA is not available, field sampling will proceed and deviations from the FSP will be documented in the field logbook. If the target 80% recovery is not achieved after three attempts, the SIB RD Group's representative will contact EPA to discuss the potential deviations prior to abandoning the location. These potential deviations may include relocating to an alternative station or potentially processing a core with a lower sample recovery percentage. The cores from each attempt will be retained until an acceptable core (as defined above) is acquired. If an acceptable core is not obtained, then the best of three attempts will be retained and processed. If recovery is poor in the three attempts (<60% recovery) then the FTL will decide and document if additional cores should be attempted and location adjusted further from the target location.

After core acceptance, water will be carefully decanted from the top of the core tube to minimize sediment disturbance. Cores will be cut horizontally into segments (approximately 4 ft long) for handling, storage, and transport. Core tubes will be capped with aluminum foil and plastic caps, scribed on the sidewalls with core and segment ID (A, B, C, etc.) and "up" arrow, stored upright with ice, then transferred upright from the sampling vessel to the processing facility, and processed immediately. Alternatively, the liner may be extracted from the entire core tube or tube segments for handling, storage, and transport directly following core collection.

During the subsurface sediment coring efforts, the field staff may encounter field conditions that preclude collection of acceptable cores at the planned location (e.g., limited access, poor recovery, safety concerns, debris/rock/bedrock causing refusal).

EPA will be kept informed of issues associated with sample recovery during the field investigation. Approximately 1,000 grams (g), wet weight, or 1 L of sediments are required for the COC analyte list. Additional material may be required at a particular location for field and laboratory quality assurance (QA)/QC. If the recovered volume of sediments at a particular depth interval is insufficient for the analytes, an additional core will be advanced within 10 ft of the location of the original core and an additional sample will be collected at the same depth.

#### *4.2.3.1.2 Core Processing and Subsurface Sample Collection*

Core logging and processing are anticipated to occur concurrently with sample collection either on the sampling vessel or at an onshore facility. Cores will be offloaded after core collection, midday and/or end of day, with every effort made for immediate processing. The processing facility will be equipped with a core extraction trays, tables, core processing area, decontamination area, and sample storage area.

Each core tube will be fixed in place and cut along the long axis using a circular saw. The tube is rotated 180-degrees and cut again. After each core is cut, the core tube will be moved to a sampling tray and opened. Alternatively, the liner may be extracted from the core tube without cutting to a sampling tray. The liner will be cut longitudinally with a decontaminated knife with a stainless-steel blade. Each sediment core will be measured for percent recovery, systematically logged and described in the field logbook and photographed prior to sampling as discussed below. See SOP A-3 Sampling Photography for further information on sampling photography.

After the core is exposed, a mini-RAE 3000 photoionization detector (PID) with 10.6 electron-volt lamp will be used for prescreening of each core. The PID monitor will be slowly moved down the core from top to bottom just above the core. PID readings will be recorded in the field logbook. If there is an elevated PID reading or if sheens/petroleum-like odors are suspected, then a headspace screening will be conducted following headspace field screening procedures described in SOP A-2 PID Screening and Calibration Procedures (Appendix A).

A qualified geologist will describe the sediment on a core log following the ASTM D2488 visual soil classification procedure in HGL SOP 403.07 (ASTM, 2017; Appendix A). The following information will be recorded for each core:

- Soil or formation name/Unified Soil Classification System (USCS) symbol;
- Gradation degree of sorting;
- Principal constituent;
- Specific descriptors for principal constituents (e.g., plasticity, grain size, and shape);
- Firmness/hardness;
- Minor constituents;
- Moisture content;
- Color;
- Particle morphology; and
- Other descriptors (such as, visual evidence of contamination, specific monitoring equipment readings including PID/organic vapor analyzer readings, visual stratification and lenses, vegetation, debris, and evidence of biological activity).

The representative sediment sample interval (e.g., 1 ft for dredging) will be collected and placed into a decontaminated stainless-steel bowl. Sediment from each subsample will be individually mixed in the decontaminated, stainless-steel bowl to a uniform color and texture using a decontaminated, stainless-steel spoon. If an aluminum core barrel is used, care will be taken to not include sediment that is in direct contact with the core tube. In addition, core tube cutting can introduce shavings to the core sediment; care will be taken to avoid mixing these shavings into the homogenate. The sediments will be stirred periodically while individual samples are taken to ensure that the mixture remains homogeneous. Pre-labeled jars for chemical testing will be filled with the homogenized sediment. The analysis to be completed on the samples is summarized in Worksheet 19 and 30 of the UFP-QAPP (see solid matrix). Collected samples will be placed in laboratory provided glass jars and stored in a cooler at 0 to 6°C until transport to the laboratory. See Section 4.9 for decontamination procedures. Adequate volumes of sediments will be collected for the required analyses.

#### **4.2.3.2 Direct-Push Sampling**

Given the potential sediment investigation time frame based on the AOC schedule, work is anticipated to occur in summer 2022. It is anticipated that water levels in the Willamette River will be relatively low and that access to Shallow Region sample stations may not be achievable by boat

or barge. To collect sediment cores from the Shallow Region, a direct-push drill rig may be deployed to the sample station from land or a shallow draft vessel with landing hatch, whichever allows for easiest and safest access (SOP 403.04). The direct-push drilling equipment will be small, maneuverable, and track mounted to facilitate access to soft, wet, and potentially uneven shoreline areas. Direct-push borings reach target depth of 10 ft using successive 4-ft long core tubes, and the acceptance criteria listed in Section 4.2.3.1.1. Each 4-ft-long tube will have a 3.25-inch outer diameter steel sample barrel lined with clear acrylic sleeves. To minimize sediment disturbance, borings will be advanced through a temporary polyvinyl chloride (PVC) casing. Once the sampler is retrieved (either to the sampling vessel or to land), the acrylic sleeve will be removed for sampling processing in accordance with Section 4.2.3.1.2.

#### **4.2.3.3 Vibracore Sampling**

For the in-water portions of the sampling area, cores will be targeted for collection using a customized vibracore deployed from the sampling vessel operated by the marine subcontractor (Section 4.2.1). The vibracore is a wireline-suspended hydraulic system that vibrates and drives a 15-ft long, 4-inch outer diameter aluminum core tube into the sediments. A continuous sediment sample is retained within the tube with the aid of a stainless-steel retainer at the bottom of each aluminum tube. A core liner may be used with this device. Following positioning at a given sampling station, the vibracore will be deployed off the foredeck of the vessel and slowly lowered to the sediment surface. The core tube will be advanced to obtain adequate core penetration (target sample depth). The core penetration depth will be estimated by means of a pressure transducer attached to the top of the core barrel. The vibracore may not be effective if gravels and cobbles are encountered. If refusal is met after three attempts, the station will be abandoned and more robust methods, such as sonic drilling, will be evaluated for the PDI.

#### **4.2.3.4 Hand Auger Sampling**

If needed, due to access limitations, subsurface sediments at Shallow Region sampling stations exposed during low water will be collected by field staff using a stainless-steel hand auger (SOP 403.02). These hand borings will be advanced through a temporary PVC casing to keep the borehole open. The hand borings will be advanced until refusal is met, likely within the upper 4 ft below mud line. Grab samples will be removed from the hand auger barrel and processed in accordance with Section 4.2.2.1. The temporary PVC casing will be removed upon completion of the hand boring.

#### **4.2.4 Sediment Erodibility (SedFlume) Sample Collection**

The sediment bed within the SIB contains both cohesive and non-cohesive sediments. Erosion and settling of non-cohesive sediments (sand and gravel), in general, can be estimated from grain size distribution and sediment density. However, for cohesive sediments that are a mixture of sand, silt, and clay sized particles, the sediment transport processes can be dominated by other factors such as particle size distribution, particle coatings, fine sediment mineralogy, organic content, bulk density, gas content, pore-water chemistry, and biological activity (USACE, 2014).

The influence of cohesion on sediment processes is significant as the critical shear stress and erosion rates for cohesive sediments can vary over several orders of magnitude for sediments with

only slightly differing properties. Due to lack of quantitative methods available to determine erosion rate from cohesive sediment properties and the sensitivity and wide range of influencing parameters, erosion characteristics of cohesive sediments will be analyzed using sediment core sampling, and site-specific erosion analysis using erosion flumes (USACE, 2014).

The SedFlume sampling program was designed based on review of previous sampling that was performed in Portland Harbor (Sea Engineering, Inc., 2006). The previous programs included two samples in the SIB: one sample near the SIB entrance and one sample in the SIB central interior. Analysis of those testing results indicates significant differences in sediment erodibility properties, including erosion rates and fines content. Therefore, a robust sampling program was determined to be warranted to capture these significant differences in sediment erodibility.

Sediment cores to be used in SedFlume analysis will be collected at 30 prescribed locations within and adjacent to the SIB project area as shown in Figure 4-5 and listed in Table 4-4. At each sediment coring location, a GPS will be used to position the vessel at a fixed sampling station. A pole will be attached with clamps to the 10 cm by 15 cm rectangular core. A valve will be temporarily affixed to the top of the core tube to provide suction when the core is pulled out of the sediment bed. The core will then be lowered into the water and positioned perpendicular to the sediment bed. Pressure will be applied by hand until at least 30 cm and no more than 100 cm of the core has penetrated the sediment bed (Sea Engineering, Inc., 2006).

Upon penetration of the core barrel into the sediment bed, the valve will open upward and allow the sediment to enter the core tube and water to exit without disturbing the sediment surface or deeper strata. When the barrel is lifted from the sediment bed, the valve will close and retain the sediment inside the core tube. The core will be immediately inspected visually for length and quality. The cores will then be capped and immediately delivered upright at ambient temperature to the SedFlume laboratory for further analysis.

Field staff will accompany the driller and a SedFlume expert (both subcontractors) in the field to observe and document core extraction and preparation of the cores for shipping, as well as to confirm proper waste management.

#### **4.2.5 Dredge Elutriate Testing**

Three samples for dredge elutriate testing (DRET) shall be collected from grid cells F14, D5, and C20 to evaluate the potential for short term contaminant releases during dredging operations. These grid cells are all located within areas where dredging is the expected remedial technology and contain a wide variety of sediment contaminant concentrations based on historical data, which will inform water quality impacts from a wide range of dredge areas. See below for more information on DRET procedures and parameters. The samples will be collected in accordance with SOP 403.08 Sediment Sampling (Appendix A) and tested for all ROD Errata #2 Table 17 Surface Water COCs (Table 4-5). The results from DRET shall be evaluated against both chronic and acute water quality criteria as defined in Section 4.2.5.2, and used to support EPA's development of performance standards for use during dredging operations.

#### 4.2.5.1 **Bulk Sediment Sampling and Testing**

- Bulk sediment samples are required for disposal characterization and DRET for sediment treatability and handling properties. The analytical results will inform whether the dredged sediment is hazardous or nonhazardous for disposal purposes. Investigation-derived waste will be properly characterized and disposed of by NRC-US Ecology, which has been performing this task for other RD areas under agreement with Gravity Marine. The bulk sediment testing has been designed to inform and to fill the following data gaps: **Contaminant Release and Water QC During Dredging**. Elutriate water samples from bulk sediment will be analyzed by DRET to evaluate the potential for short-term releases during dredging operations. DRET procedures are described in *Evaluation of Dredged Material Proposed for Disposal at Island, Nearshore, or Upland Confined Disposal Facilities – Testing Manual* (USACE, 2003). In addition to DRET, these elutriate water samples will also be analyzed for bulk chemistry and conventional parameters to inform compliance with applicable water quality permitting requirements during dredging.
- **Dredged Material Disposal Characterization**. Samples of the bulk sediment, as collected and after amendment, will be tested as specified in the Resource Conservation and Recovery Act by the toxicity characteristic leaching procedure and for ignitability, corrosivity, and listed waste to characterize dredged sediments for disposal. See Worksheet 15 of the UFP-QAPP for the required analytes. Samples will also be analyzed for bulk chemistry (see the waste soil matrix in Worksheets 19 and 30 of the UFP-QAPP) to inform compliance with potential disposal facility acceptance criteria. Collected samples will be placed in laboratory provided glass jars and stored in a cooler at 0 to 6°C until transport to the laboratory.

#### 4.2.5.2 **Dredge Elutriate Testing**

DRET will be completed on the three bulk samples per the procedures described in *Evaluation of Dredged Material Proposed for Disposal at Island, Nearshore, or Upland Confined Disposal Facilities – Testing Manual* (USACE, 2003). Elutriates will be generated from initial slurry concentrations of 1 gram per liter (g/L) and 10 g/L. The elutriate (i.e., DRET bulk water samples) will be tested for bulk chemistry and conventional parameters, including the constituents listed in ROD Errata #2 Table 17 (EPA, 2020), to inform compliance with applicable water quality permitting requirements during dredging. Table 4-5 lists the constituents that will be analyzed in the elutriate and the associated surface water screening level. Screening levels are based on the EPA National Recommended Water Quality Criteria. For constituents where the water quality criteria do not have numerical values, screening levels were based on the following:

- Oregon Administrative Rule 340-041-8033 Table 30: Aquatic Life Water Quality Criteria for Toxic Pollutants; and
- Oak Ridge National Laboratory Toxicological Benchmarks for Screening Potential Contaminants of Concern for Effects on Aquatic Biota (Suter and Tsao 1996).

### **4.2.5.3 Bulk Sediment and Surface Water Sampling**

A second vibracore will be collected at select locations to perform bulk sediment testing including waste characterization and DRET for stabilization and handling to support RD. Surface water samples for the DRET slurries will be collocated with the DRET sediment sampling locations. The surface water samples will be composited to provide a single bulk water sample for DRET slurry and treatability testing. Volumes required for DRET testing include two, 5-gallon containers and two, 5-L containers.

## **4.3 RIVERBANK CHARACTERIZATION**

This section describes riverbank material sample collection procedures. The riverbank characterization will be completed in two phases. The first phase will include a reconnaissance of the entire riverbank within the SIB Project Area and completion of a bank stability analysis using the Bank Assessment for Non-point Source Consequences of Sediment (BANCS) model including Bank Erosion Hazard Index and Near Bank Stress determinations to identify the erodibility of the riverbank. The first phase of the proposed riverbank characterization includes assembly of existing chemical, topographic and geomorphic data and visually inspecting the riverbank and material types to determine input parameters for the BANCS evaluation. The reconnaissance will occur at 126 transects between the top of the bank and the toe of the bank at mean lower low water along the SIB riverbank (Figure 4-6). The first phase reconnaissance would be performed when water levels are at their lowest in SIB (anticipated for late 2021 or early 2022). After this visual inspection, HGL will provide a riverbank sampling plan as a Field Sampling Plan Addendum with the data quality objectives and proposed sampling locations.

The field teams will carefully and completely document the as-sampled location information for incorporation into the project geographic information systems (GIS) database.

Because homeless people are present in the city's Swan Island boat ramp parking lot and the adjacent riverbank (i.e., head of SIB), an outreach strategy and protocol will be included as an appendix to the HASP.

### **4.3.1 Riverbank Data Characterization**

Characterization data was available for only three shoreline properties in the SIB Upland Area, including city property and public boat ramp at the end of SIB, and two former operable units of the SUIF (Portland Shipyard and Port property on N Lagoon Avenue). The historical riverbank sample results for these three sites were evaluated in Section 6 and Appendix E of the draft Sufficiency Assessment Report (HGL, 2021). ROD CULs for riverbank soil and in-water sediment and PCB RAL exceedances were identified. Detected concentrations of metals, PCBs, and PAHs exceeded the ROD CULs at the Portland Shipyard, and PCBs exceeded the RAL and PTW threshold. Because the lateral extents of the exceedances were not defined and/or all ROD COCs were not analyzed, these conditions were identified as data gaps for the PDI and additional characterization proposed.

The objective of this task is to continue evaluating the existing physical and chemical data available along the riverbanks in the SIB Project Area (see Figure 4-6) and review findings of the

Sufficiency Assessment Report regarding the riverbanks and adjacent uplands. These findings will be used to inform additional riverbank shoreline inspection and chemical characterization (i.e., riverbank reconnaissance) of the SIB Project Area shoreline properties as described in Section 5.3. Evaluation of existing SIB riverbank data/information will include a review of available site plans, topographic maps, aerial photographs, LiDAR maps, geologic maps, riverbank and near shore soil and sediment sampling data, boring logs, geotechnical reports, and other reports previously submitted to EPA or the Oregon Department of Environmental Quality (ODEQ) with respect to ROD riverbanks or riverbank Environmental Cleanup Site Information (ECSI) sites.

#### **4.3.2 Riverbank Physical Inspection and Erodibility Evaluation**

The purpose of conducting riverbank reconnaissance is to evaluate physical riverbank/shoreline conditions, per the *Guidance for River Bank Characterization and Evaluations at the Portland Harbor Superfund Site* (EPA, 2019b), and as summarized in the PDI Work Plan, including:

- extent and type/size of river armoring (percentage of bank covered by each type of armor);
- general condition of armoring (i.e., whether the material is stable, unstable, or sloughing into the river);
- observation of previous riverbank source control measures for integrity in providing protection against erosion, visual classification of unarmored riverbank soil types following ASTM D2488 (ASTM, 2017), and the USCS visual soil classification procedures;
- visual observations, topographic measurements, and photographs to document the physical characteristics of the riverbank;
- evidence of shoreline erosion and/or instability due to overland flow, wave and/or vessel wake, or other factors;
- location of armoring relative to the toe of the slope, top of the bank, and ordinary high-water elevation;
- presence of vegetation including vegetation type, rooting depth and density, and the percentage of the riverbank surface that is covered by vegetation; and
- presence of aquatic vegetation.

During the site reconnaissance, erosional scours, scarps, slumps, and landslides on the riverbanks, if present, will be mapped and recorded with a hand-held GPS unit as a location of current and/or future erosion potential of soil to the river. Characterization will extend from the top of the riverbank to the mean low water, or the lowest elevation visible at the time of inspection.

The field team will collect the following riverbank physical and material characteristics to support a quantitative evaluation, if needed:

- Height of the bank: Riverbank height is measured from the top of the bank, defined as the point where the slope of the land surface changes from toward the river to toward the

uplands, to the toe of the slope, defined as the first significant break in slope that is below ordinary high water (OHW) but above mean high water. Bank height can be difficult to determine in the field and should be measured using survey methods. Bank height may instead be determined from topographic and bathymetric maps.

- **Bankfull level:** Bankfull level is the point on the riverbank that contains normal, non-flood-level flows of the river throughout the year and is typically identifiable by visible changes in topography, vegetation type, or sediment grain size (EPA, 2019b). For the Willamette River, the bankfull level is approximated by the OHW elevation, which is equivalent to 20.08 ft North American Vertical Datum of 1988 (NAVD88) (USACE, 2014).
- **Bank angle:** The maximum bank angle between the toe of the slope and the top of the bank will be determined from topographic or bathymetric maps or measured in the field using a clinometer or other suitable direct field measurement technique.
- **Surface protection:** Surface protection is the amount of the riverbank that is covered and protected by woody debris, rooted vegetation, embedded boulders, revetment, bedrock, or other embedded materials that protect the bank from erosion (EPA, 2019b). Riverbank surface protection will be assessed in the field and visual observations recorded, including:
  - o Type and size of protection, the location relative to the toe of the slope, top of the bank, and OHW elevation.
  - o Percent of the riverbank surface protected and general condition of protection if the protection is afforded by armoring.
  - o General condition of the armoring, including whether the material is stable, unstable, or sloughing into the river. If the riverbank is vegetated, the general vegetation type and the percentage of the riverbank surface that is covered by vegetation will be documented. The vegetation types will be used to infer rooting depth and density.
  - o Bank composition, which is the soil type(s) that comprise the riverbank.

Field classifications will be performed using the procedures described in ASTM Standard D2488, Standard Practice for Description and Identification of Soils (ASTM, 2017). Riverbank samples may be collected for sieve analysis to supplement visual classification and verify grain-size distribution.

During this inspection, a Physical Shoreline Inspection Form will be completed to document the conditions observed. This will be done for each tenth of an RM throughout the SIB Project Area. This field form is included in Appendix B and was developed to allow field personnel to collect the relevant information detailed in the *Guidance for River Bank Characterizations and Evaluations at the Portland Harbor Superfund Site* (EPA, 2019a). Additional relevant field forms for Bank Erosion Hazard Index (Rosgen, 2014), Structural Inspection, and Near Bank Stress Risk are also available in Appendix B. Photographs will be taken to document areas of interest, including areas of visible erosion, armoring, permanent structures, and vegetation. The areas of interest will also be documented using a handheld GPS unit (e.g., Trimble Geo 7x), providing the ability to map these features for use in the PDI Evaluation Report. A GPS unit will provide

approximate +/- 1 meter accuracy with daily check-in to known benchmarks. Tolerance to known benchmark check-ins shall be no greater than 5 meters, with typical performance expected to be within 2 to 5 meters.

### **4.3.3 Riverbank Soil Characterization**

The SIB riverbanks will be accessed by field staff via upland areas or by boat where upland access is restricted. Most areas are accessible through the facility properties and field staff will follow the sign-in/sign-out protocols for the respective facilities. A total of 126 transects (1 per every 100-lineal-ft) are targeted for visual inspection and possible sample collection at the top, face, and toe of the bank (mean lower low water) at low water levels using manual and hand auguring field techniques. If the 126 transects can be sampled successfully to the planned depth of 3 ft, 126 surface soil samples and 126 subsurface soil samples will be collected at the top, face, and toe of each transect along the bank. Pursuant to EPA's recommendation in its September 24, 2021, comments on the Draft FSP, the sampling plan for the head of the lagoon will differ from that along the rest of the SIB because of the homogeneous nature of this area (i.e., sandy beach and riverbank consisting of dredge material). Incremental sampling methodology will be applied to this 700-ft wide area (ITRC, 2020), including the collection of 30 aliquots of soil from two decision units, surface and subsurface soil, per the 0.29-acre area. Locations will be selected using a random number method and overlaid on a proposed sample location plan.

Before collecting soil samples, a clean plastic-covered workspace will be established on the ground surface. Sample bottles will remain covered in plastic bags inside the plastic-lined ice chests until ready to be filled. Shallow soil borings will be advanced, via hand auger, to a depth of 3 ft vertically below ground surface into the bank, perpendicular to the ground surface, and samples will be collected continuously on 1-ft (~30-cm) sampling intervals (SOP 403.02). Surface soil samples will be collected using decontaminated (or single use) hand tools (SOP 403.06). The top layer of vegetation and gravel, if any, will be temporarily moved in an area at least 6 inches in diameter.

Soil samples will be visually characterized for sediment type, color, moisture content, texture, grain size and shape, sheen/odor, consistency, visible evidence of staining, and other observations. Samples will be visually described following USCS-based, visual-manual ID in accordance with the ASTM D2488 standard practice (ASTM, 2017). A logging key of the visual classification method is provided in Attachments 1 through 5 of SOP 403.07. The colors will be designated using a Munsell color chart. This information will be recorded on the Borehole Log Field Form (SOP 403.07).

Olfactory observations (odors) or positive responses to an organic vapor detector will be recorded on the soil boring log. Examples of odors may include, but are not limited to, sulfur/sulfide, petroleum, and fuel-type odors. If potential sheen or NAPL is observed, descriptions detailed in SOP A-1 Hydrocarbon Field Screening must be used to record field observations (Appendix A). The depth where signs of NAPL begin and end (including olfactory, visual, and MultiRAE/PID observations) will be noted in the boring log.

The samples will be analyzed for the solid (chemical analysis only) parameters listed in Worksheets 19 and 30 of the UFP-QAPP. Collected samples will be placed in laboratory provided glass jars and stored in a cooler at 0 to 6°C until transport to the laboratory. Hand augers will be

decontaminated between sampling intervals. Upon completion of sampling at each boring location, the hole will be backfilled with native material and topsoil, vegetation, or armoring will be replaced to the extent possible. If refusal is met, sample locations will be relocated. Up to three attempts will be made to relocate soil borings. Coordinates for every sampling station where a sample is collected will be read on a handheld GPS and recorded in the field notes or tablet.

#### **4.4 GEOTECHNICAL INVESTIGATION**

The following section describes the procedures and sample processing techniques for the collection of geotechnical information in the SIB Project Area. Boring and cone penetration test (CPT) locations are shown on Figure 4-7 and listed in Table 4-6. Analytical methods are summarized in Table 4-1.

##### **4.4.1 Investigation Location and Utility Clearance**

A site reconnaissance will be performed to identify and review site health and safety issues, locate proposed exploration locations, and identify other logistical issues in accordance with Section 4.1.

##### **4.4.2 Exploratory Borings**

Exploratory borings are planned both within the SIB (in water), and on the surrounding wharf structures and bank (on land). A licensed drilling subcontractor will provide drilling services. On-land borings will be advanced with a truck or track-mounted drill rig equipped with rotary wash and/or auger drill tooling. In-water borings will be drilled from a dedicated drill ship equipped with a rotary wash drill rig, a central moon-pool, and hydrostatically controlled spuds capable of holding the vessel in water depths of up to 55 ft.

Existing semi-empirical correlations will be used to estimate geotechnical parameters from the CPT sampling results (cone tip resistance,  $q_c$ , and “sleeve friction”,  $f_s$ ) including but not limited to over consolidation ratio, undrained shear strength, relative density, one dimensional compressibility, and Young’s and shear moduli.

Both on-land and in-water borings will be initially identified in the field with a hand-held GPS device, and in-water will be advanced to a termination depth of approximately 50 ft below the mudline. Prior to drilling, a weighted line will be used to determine the depth of the mudline relative to the deck of the drill ship. Following drilling, the mudline elevation will be estimated based on bathymetric survey data, GPS location data, and the water level at the time of drilling. Final “as-built” boring locations will be identified using real-time kinematic positioning observations with a horizontal precision of less than or equal to 0.03 ft, and a vertical precision of less than or equal to 0.05 ft. Horizontal positions of the as-built boring locations will be recorded in the North American Datum 1983 (NAD83), Oregon North coordinate system (international ft).

Standard penetration tests will be conducted in accordance with ASTM D1586 (ASTM, 2018), with consideration given to ASTM 1587 and 3550. Standard penetration test blow counts will be logged in accordance with ASTM D1586. Standard penetration test, thick-wall ring lined, and thin-walled samplers will be used to obtain soil samples at selected intervals at 2 to 3 ft in the upper 15 ft and at 5-ft intervals thereafter. For efficiency in the deeper borings, the sampling interval may

be extended in the field depending on the expected stratigraphy and data needs; however, sampling will be focused on the areas of interest for analysis of the relevant structure or project component. Estimates of the undrained shear strength of cohesive soils will be made using a hand-held pocket penetrometer or torvane shear device, as appropriate.

In general, on-land borings will be advanced to a termination depth of roughly 60 ft below adjacent ground, and in-water borings will be advanced to a termination depth of approximately 50 ft below the mudline. Drilling and sampling equipment will be decontaminated before beginning each new boring as described in SOP 411.02 (Appendix A). Drilling spoils and excess fluids will be containerized and stored on site for testing and disposal. Testing and disposal of investigation derived waste is described in Appendix C.

Borings will be logged by a field engineer or geologist who will package samples and transport them to the laboratory for further evaluation and testing. Logging will be performed in accordance with the geotechnical soil logging SOP R-4 (Appendix A) and recorded on forms within SOP R-4. Observations the field logger will document include but are not limited to:

- Borehole diameter;
- Variation in drilling conditions throughout boring depth;
- Drill cuttings;
- Drill crew drilling observations;
- Variation in samples or cuttings with depth;
- Moisture content (dry, moist, wet) will be noted where possible since drilling fluid may affect observed moisture content;
- Sample type, diameter, depth interval, pressure, and recovery percentage; and
- Soil classification in general accordance with ASTM D2488 (ASTM, 2017).

Soil samples obtained from the borings will be packaged and sealed in the field to reduce moisture loss and disturbance, then transported in general accordance with ASTM D4220 (ASTM, 2014).

#### **4.4.3 Cone Penetration Testing**

Both on-land and in-water CPTs will be conducted by hydraulically pushing an instrumented steel cone into the ground in general accordance with ASTM D5778 (ASTM, 2020). On-land CPTs will be performed with a 25-ton CPT truck rig and in-water CPTs will be performed from the same dedicated drill ship used to perform the rotary drilling and soil sampling. The instrumented cone assembly includes a cone tip with a 60-degree apex and a cone base area of 15 square cm, a friction sleeve segment with a surface area of 225 square cm, a pore pressure transducer mounted near the base (shoulder) of the cone tip, and geophone sensors located just above the friction sleeve. Downhole shear wave velocity measurements will be performed at select CPT locations, at approximately 3-ft intervals, for the full depth of the sounding. Pore-water pressure dissipation tests to evaluate static piezometric pressure will be performed at both on-land and in-water CPT locations.

Both on-land and in-water CPT locations will be initially identified in the field with a hand-held GPS device. Final “as-built” CPT locations will be identified using real-time kinematic positioning observations with a horizontal precision of less than or equal to 0.03 ft, and a vertical precision of less than or equal to 0.05 ft. Horizontal positions of the as-built CPT locations will be recorded in NAD83, Oregon North coordinate system (international ft).

In general, both on-land and in-water CPTs will be advanced to a termination depth of approximately 100 ft, or practical refusal, whichever occurs first. CPT tooling will be decontaminated before beginning each new boring as described in Section 4.9.

#### **4.4.4 Boring and Cone Penetration Test Abandonment**

At the completion of the drilling, borings will be abandoned in accordance with Oregon Water Resources Department requirements (Oregon Administrative Rules 690-240-0005), which involve filling the hole by tremie with bentonite grout slurry to prevent vertical migration of groundwater. The driller will certify the proper abandonment by filing a Geotechnical Hole Report with the Oregon Water Resources Department.

#### **4.5 STORMWATER AND STORMWATER SOLIDS SAMPLING**

Current stormwater and stormwater solids concentrations are needed to help determine ongoing ROD Table 17 COC concentrations and loads to the SIB sediments. Samples will be collected from five city of Portland outfall basins (M-1, M-2, M-3, S-1 and S-2) as well as select private outfall basins along the shoreline of the SIB (Table 4-7 and Figure 4-8). Equipment will be placed at elevations sufficient to minimize the potential for river water to backflow to the sample locations and compromise flow data quality, the integrity of the sediment traps, and collection of stormwater samples representative of discharges in upland outfall basins.

Techniques for obtaining stormwater samples from city conveyance systems include using a high-volume sampling (HVS) system to collect and process each sample set (Gravity Marine PR2900). The system consists of a high-volume peristaltic pump or submersible pump, depending on the depth of the water in the manholes, and a series of filters to capture the particulate phase and a resin column to capture the dissolved fraction of focused ROD COCs. Stormwater collected via the high-volume pump will be run through an HVS system to separate stormwater and stormwater solids for separate phase (dissolved and particulate) analyses. This method is used to collect samples for analysis of hydrophobic organic compounds (dioxins/furans, PCBs, and pesticides) by ultra-low detection limit analytical methods. Analysis of stormwater samples collected via the HVS method is more likely to detect lower concentrations of focused COCs resulting in method detection limits that are at or below the CULs in ROD Errata #2 Table 17 (EPA, 2020). This method also allows for quantification of hydrophobic organic chemicals in the suspended particle and dissolved phases of the water column. EPA has approved the Gravity Marine PR2900 sampling system for the collection of representative surface water and stormwater samples in the PHSS (AECOM Technical Services [AECOM] and Geosyntec Consultants, Inc. [Geosyntec], 2018; and Foth Infrastructure & Environment, LLC, 2021). In addition to the samples collected by the HVS system, physical field measurements and a separate whole water sample will be collected using a separate pump and carboy.

Stormwater sampling criteria will be consistent with the criteria in Appendix D of the 2005 ODEQ and EPA Joint Source Control Strategy (JSCS) guidance:

- An antecedent dry period of at least 24 hours (as defined by less than 0.1 inch of precipitation over the previous 24 hours)
- A minimum predicted rainfall volume of greater than 0.2 inch per event
- An expected storm duration of at least 3 hours.

The storm will be tracked via the NOAA, National Weather Service, local media outlets, and the Windy forecast at [www.windy.com](http://www.windy.com) to anticipate the length of the storm event and to determine if the storm event will meet the Portland Harbor JSCS storm event criteria.

Because homeless people are present in the city's Swan Island boat ramp parking lot where manhole AAQ-004 (M-3 outfall basin) is located (i.e., head of SIB), an outreach strategy and protocol will be included as an appendix to the HASP.

In addition to collecting stormwater solids via the HVS method, stormwater solids will be collected by 1) manual grab sampling from public manhole sumps and adjacent laterals in the conveyance systems prior to installation of sediment traps; and 2) time-integrated, in-line, sediment traps within the public conveyance system.

Pulsar Measurement Greyline Stingray 2.0 level-velocity loggers will also be incorporated into the stormwater sampling program in the city outfall basins to continuously measure water levels and velocities over a 9-month period.

Because of the smaller size of the private outfall conveyance systems along the SIB shoreline, HGL proposes to equip the conveyance systems with Teledyne ISCO<sup>®</sup> portable autosamplers (6712C with flow sensors) to collect time-weighted, composite, stormwater samples, and flow measurements at elevations unlikely to be affected by backflow of river water during storm events during the same or similar storm events as the HVS samples. Manual grab samples of stormwater solids, if present, will also be collected in the private conveyance systems before deployment of the portable samplers.

HGL proposes to monitor portions of the private systems with the largest drainage basins, and that are most ROD COCs in direct discharges to SIB. These systems are associated with the following properties as shown on Figure 4-8: U.S. Coast Guard Marine Safety Unit Portland, ATC Leasing Co., Barge Eagle, Inc./Swan Island Boast Company, North Basin Watumull, DTNA Corp 5 Wind Tunnel, and the Port of Portland's North Lagoon Avenue property. HGL proposes to instrument conveyance systems to the outfalls with autosamplers with flow meters and possibly in-line solids traps (depending on access) and collect stormwater and solids samples during rain events meeting the ODEQ-EPA JSCS criteria, as described above. The exact sampling locations in the private conveyance systems will be identified after site access agreements have been negotiated and site inspections have been performed, and a list of them will be submitted to EPA for approval prior to equipment deployment and monitoring.

Solids will be visually described following ASTM D2488 (ASTM, 2017) and the USCS visual soil classification procedures.

The types of samples that will be collected at each of the proposed sample locations are shown on Figure 4-8.

#### **4.5.1 HVS Sampling Methodology for City Outfall Basins**

Stormwater and stormwater solids will be collected during three storm events that meet the JSCS criteria. Time-weighted samples will be collected by pumping large quantities of stormwater from city manholes with a high-volume peristaltic or submersible pump, depending on water depth, and processing the water through an HVS system. This work is proposed to be conducted by Gravity Marine with HGL oversight. High-volume water samples will be collected to quantify concentrations of targeted organic chemicals (e.g., dioxins/furans, PCBs, and pesticides) that could be present at levels too low to be detected using conventional sampling methods. This method also allows for quantification of hydrophobic organic chemicals in the suspended particle and dissolved phases of the water column. Stormwater and stormwater solids collection will be performed in accordance with SOP A-5 Gravity Marine HVS Sampling (Appendix A). A Pulsar Measurement Greyline Stingray 2.0 flow sensors will also be incorporated into the HVS stormwater program to continuously measure flow and volume during each HVS storm event and during an approximate 9-month period to measure seasonal flow trends.

Stormwater samples to be analyzed for ultra-low concentrations of organic compounds will be collected using a high-volume peristaltic pump (with no screen) with both platinum silicone tubing and extended Teflon™-lined polypropylene sample tubing lowered to the desired depth within the conveyance system. This sampling method is required to achieve the very low ROD focused COC CUL, which are below standard method reporting limits, for PCBs, dioxins/furans, and organochlorine pesticides (OCPs). Water pumped at a rate of up to 1.5 liters per minute (L/min) will be drawn through Teflon™ tubing and through each filter set. The pump rate will be managed to collect a minimum of 200 L over each storm event which typically last 4 to 6 hours. The HVS system can be paused if the stormwater flow temporarily subsides due to fluctuating precipitation rates. The rate of water pumped through the HVS will be checked at 15-minute intervals to ensure that water is flowing at a constant rate using a 1-L graduated cylinder and a timer. If the pump is not delivering the correct flow rate, fine adjustments will be made until the optimum flow is achieved. If a submersible pump is required because of the water depth in the manholes, the water will be pumped through Teflon coated tubing going to an intermediate 8-gallon carboy first, and then through the same type of tubing from the carboys to the HVS pump and standard peristaltic pump. The pumps will be turned on/off to maintain the level in the carboys at approximately 80% capacity without overflowing.

Within the HVS system, the stormwater will pass sequentially through a high vortex separator, a 0.45-micron glass fiber filter (142 millimeter [mm]), and a polyurethane foam (PUF) cartridge. The high vortex separator can separate suspended sediments by forcing the water in a centrifugal fashion. Solids collected from the vortex separator and 0.45-micron glass fiber filter will be combined, homogenized, and placed into appropriate sample containers for analysis. A list of required sample containers and preservatives can be found in Worksheets #19 and #30 of the UFP-QAPP. The compounds that bind to the adsorbent PUF material will be extracted and measured on

a gas chromatograph/mass spectrometer at the selected laboratory (SGS North America, Inc. [SGS]). Samples will be stored in a cooler at 0 to 6°C and sent to SGS for analysis.

Physical field measurements and a separate whole water sample will be collected in tandem with the HVS system sampling by connecting a second Teflon™-lined polypropylene tube to a second peristaltic pump, tubing set, and carboy with mixing chamber. This pump will have a flow-through chamber with a YSI Exo multi-meter installed for continuous measurement of dissolved oxygen, pH, turbidity, and temperature. A subset of stormwater collected in the carboy will be placed into appropriate sample containers for total suspended solids (TSS) and total organic carbon analysis. Required sample containers can be found in Worksheets #19 and #30 of the UFP-QAPP. Those sample bottles and the full volume of the carboy will then be stored in a cooler at 0 to 6 °C and transported to the selected laboratory for processing and analysis. The whole water sample will be analyzed for ROD Table 17 COCs, except the PCBs, OCPs, and dioxins and furans. If there is a sufficient volume of stormwater solids available in the carboy after the removal of the whole water sample, those solids will be separated by centrifuge in the laboratory and analyzed for ROD Table 17 COCs, except the PCBs, OCPs, and dioxins and furans.

## **4.5.2 Calculating Dissolved, Particulate, and Total Fractions from HVS Samples**

### **4.5.2.1 Particulate Phase**

Stormwater samples will be collected using the PR2900 HVS connected to a vortex solids separation system and a 0.45-micron glass filter. The high vortex separator captures suspended sediments by forcing the water in a centrifugal fashion before exiting toward the 0.45-micron glass filter and then the PUF cartridge. The solids captured in the vortex separation system and the solids on the glass filters will be placed in one sample container and shipped to the selected laboratory. The combined solids sample is referred to as the “Front Half” of the HVS system and will be analyzed by the selected laboratory to represent the total particulate phase fraction of ROD focused COCs collected throughout the storm. The concentration data from the particulate fraction will be used to 1) mathematically calculate the particulate phase portion of the whole water concentration (see Section 4.5.2.1.2), and 2) mathematically calculate the particulate concentration in units of solids, for comparison to the PHSS sediment CULs (see Section 4.5.2.1.3).

To support the second calculation, TSS will be measured by ALS Global from a sample collected from the carboy via a second peristaltic pump (SOP A-5 Gravity Marine HVS Sampling, Appendix A).

#### *4.5.2.1.1 Dissolved Phase*

After stormwater has been pumped through the “Front Half” of the HVS system and solids have been removed via the high vortex separator and 0.45-micron glass filter, the water will enter the “Back Half” of the HVS system and be drawn through the PUF cartridge. The cartridge will contain solid phase extraction resins that bind dissolved forms of the compounds in question (e.g., PCBs). Once the HVS system has been turned off, the sealed PUF cartridges will be labeled and sent to SGS for analysis of the dissolved fraction of PCB congeners, dioxins/furans, and OCPs in stormwater. These analyses are listed for the aqueous matrix in Worksheets #19 and #30. Collected

samples will be placed in laboratory provided glass jars and stored in a cooler at 0 to 6°C until transport to the laboratory.

#### *4.5.2.1.2 Whole Water Concentration*

One objective of the HVS sampling method will be to quantify the PCB congeners, dioxins/furans, and OCPs concentrations in stormwater at levels that are below, or similar to, the low level CULs established for surface water in PHSS. This section describes how to convert the mass measurements provided by the laboratory into a whole water concentration that can be compared to PHSS surface water CULs.

The laboratory will report the total mass of the particulate (i.e., “Front Half”) and dissolved phase (i.e., “BackHalf” driver COCs) in laboratory reports in units of picograms (pg). Once that data has been validated, it will be used to mathematically calculate whole water concentrations using the following equation.

$$\frac{\text{Particulate Phase (pg)}}{\text{Sample Volume (L)}} + \frac{\text{Dissolved Phase (pg)}}{\text{Sample Volume (L)}} = \text{COC Concentration (pg/L)}$$

where:

- Particulate phase is the analytical sample consisting of the solids from the vortex and glass microfiber filters (pg/sample);
- Dissolved phase is the dissolved fraction adsorbed to the PUF cartridge (pg/sample); and
- Sample volume is the total amount of water passed through the PR2900 during sample collection (L).

As noted in SOP A-5 Gravity Marine HVS Sampling (Appendix A), a minimum target volume of 200 L of water will be pumped through the system. Flow rates will be low (approximately 1.5 L/min) to allow for adsorption of dissolved-phase COCs to the PUF cartridge and to ensure that equal representation from the storm is reflected in the combined analytical results. Each storm and associated location will have different total volumes pumped. These volumes will be provided by the subcontractor and used by HGL in these calculations.

#### *4.5.2.1.3 Particulate Phase Concentration*

A second objective of the HVS sampling method is to capture enough stormwater solids to quantify the concentration and loading rate of those solids discharging from the city outfalls to the Willamette River and evaluate the risk of on-going recontamination to sediment near the outfalls. This section describes how the particulate phase mass provided by SGS (in pg) and the TSS measurement provided by ALS Global (in milligrams per liter [mg/L]) will be used to calculate the focused COC concentrations in stormwater solids, which can then be compared to the PHSS CULs and RALs.

After the laboratory data are validated, the data will be used to mathematically calculate whole water concentrations in picograms per milligram (pg/mg) using the following equation.

$$\frac{\frac{\text{Particulate Phase (pg)}}{\text{Sample Volume (L)}}}{\text{TSS (mg/L)}} = \text{COC Concentration } [\mu\text{g/kg}]$$

where:

- Particulate phase is the analytical sample consisting of the solids from the vortex and glass microfiber filters (pg/sample);
- Sample volume is the total amount of water passed through the PR2900 during sample collection (L);
- TSS is the concentrations (in mg/L) measured from an aliquot of water collected from the carboy sample; and
- The resultant ROD focused COC concentration is in micrograms per kilogram, which is equivalent to pg/mg.

### **4.5.3 Automatic Stormwater Sampling Methodology for Private Outfalls**

During the three storm events selected for HVS or similar events meeting ODEQ-EPA JSCS criteria, as defined above, time-weighted, composite stormwater samples will be collected from six locations using automatic samplers to provide a “snapshot” of COC concentrations discharging to the SIB during rain events meeting the ODEQ-EPA JSCS criteria similar to the HVS samples collected in city outfall basins, although during shorter sampling duration events. Time-weighted, composite samples will be collected during storm periods expected to have higher chemical concentrations (e.g., first flush or rising limb), to increase the likelihood of detecting COCs if discharging in stormwater.

Autosamplers (e.g., Teledyne ISCO® 6712C portable samplers with flow meters) will be used to collect grab samples from small private conveyance systems to assess whether COCs in stormwater are controlled prior to removal action. The samplers will be automatically programmed to collect samples to evaluate COC concentrations discharging to SIB and the need for source control measures. Proposed private facility locations were selected based on the location of discharges relative to SMAs, ROD CUL/RAL exceedances, and/or lack of data adjacent to SMAs.

The autosamplers will be installed at locations that best represent stormwater flow to selected outfalls to SIB. The autosamplers will either be installed inside a stormwater feature (manhole or catch basin) or stored adjacent to the feature at ground level depending on location conditions, access, and security. The autosamplers will be connected to a compatible flow sensor that will establish when flow is elevated above baseline conditions and record real-time velocity and volume. The autosampler will have a dedicated 5-gallon whole water sample container from which the sampler will pump representative unfiltered stormwater at a rate and frequency dependent on the measured flow rate and volume (i.e., a storm-event, time-weighted, and composite sample). The autosampler will be programmed to collect sample water throughout an event meeting JSCS criteria, pausing when flows temporarily subside during "flashy" storm events. The autosampler will be monitored and potentially controlled by a remote laptop and field crews may check the autosampler to ensure that it is working properly. After the whole water sample has been collected, the field crew will retrieve the sample container and deliver it on ice to the processing facility,

where the stirred volume will be subsampled for ROD Table 17 COCs. Minimum analytical holding times and preservative requirements will be observed.

The automatic samplers are proposed for deployment in the private systems because the systems are too small and convey too little flow to support the use of the HVS sampling approach. Compared to a grab sample, the HVS methodology approach provides a superior characterization of chemical loading rates by accounting for the variability of COC concentrations over the range of variable discharge rates. HVS sampling also provides a means of determining COC loading rates when COC concentrations in stormwater are low. Automated samplers do not provide the same benefits as the HVS methodology, but they are superior to grab samples because they provide flow measurements that are correlated with the timing of sample collection such that samples are obtained consistent with ODEQ/EPA 2005 JSCS guidance (i.e., samples will be collected within 3 hours of the onset of discharge, and a minimum of one sample will be collected during the first flush [defined in the JSCS as the first 30 minutes after the onset of discharge]) (ODEQ and EPA 2005).

#### **4.5.4 Manual Grab Stormwater Solids Sampling Methodology**

Manual grabs to collect stormwater solids from manhole sumps and/or adjacent pipe inlets will be conducted in a single sampling event. Sampling will be performed in accordance with SOP A-4 Storm Drain Sampling (Appendix A).

Sample collection from manhole sumps and/or adjacent conveyance systems will incorporate material representative of the total depth of accumulated solids. The stormwater solids sampling subcontractor will select sampling equipment that is suitable for site conditions. Sampling equipment will be decontaminated prior to use. Section 4.9 provides more detailed information on decontamination procedures.

Any standing water in the manhole sump will be pumped out to ensure collection of a representative sample of stormwater solids. Firm solids above the water line are most easily collected using manual tools such as a stainless-steel spoon, scoop, or trowel. If necessary, the spoon, scoop, or trowel may be attached to an extension pole to reach the bottom of the manhole and/or adjacent pipe inlets, provided a representative sample can be recovered intact. Sample collection will avoid scraping the pipe walls to prevent the collection of iron precipitate. Stainless steel bucket augers (hand augers) typically have long handles (>4 ft) and can also be used to collect solids from deeper junctions. While it may be possible to sample solids in manhole sumps without confined space entry, manholes without sumps or without visible solids may require confined space entry to determine if sufficient solids have accumulated in the adjacent conveyance systems for collection. If no or limited solids are present, it will be noted in the field documentation and an alternative nearby manhole may be selected for evaluation based on consultation with the HGL PM and technical leader.

Clean and appropriate sampling equipment will be advanced into the manhole sump, where present, to collect solids in each pipe inlet entering the manhole. Solids will be described following ASTM Standard D2488 (ASTM, 2017) and the USCS visual soil classification procedures. Collected solids will be placed in laboratory-provided glass jars and stored in a cooler at 0 to 6°C

until transport to the laboratory where they will be frozen for possible future analyses, if inadequate volumes are collected from in-line sediment traps installed in the system.

#### **4.5.5 In-Line Sediment Trap Sampling Methodology**

In-line sediment traps will be installed in select locations in the city’s conveyance system during December 2021 if the city grants access. In-line sediment traps will consist of custom stainless-steel brackets holding 1-L high-density polyethylene sample bottles. At each designated sampling location, in-line sediment traps will be installed at the bottom of the conveyance system. In-line sediment traps will be firmly secured to the conveyance system to prevent unintended transport of the equipment. It is anticipated that confined space entry procedures will be required to install the sediment traps. These procedures will be outlined in the HASP. In-line sediment trap brackets and related equipment will be decontaminated prior to installation and new clean laboratory supplied 1-L bottles will be utilized within the brackets.

Each trap is equipped with four, laboratory-supplied, 1-L, wide-mouth, polyethylene bottles. The sample bottles will be removed and replaced at the end of February, April, and June 2022 for compositing and analyses representing wet season accumulation. Bottles will be deployed from June 2022 until October 2022 before the wet season first-flush event and analyses will represent dry weather accumulation. The dry season deployment may be terminated early if wet weather is predicted prior to the end of October. The locations are shown on Figure 4-8. Sampling of stormwater solids via in-line sediment traps is proposed to be conducted by an HGL subcontractor. Sampling will be performed in accordance with SOP A-6 In-Line Sediment Trap (Appendix A).

When the sample bottles are collected and submitted for archival and subsequent analysis after the first targeted deployment period, they will be replaced by clean and decontaminated bottles. Section 4.9 provides more detailed information on decontamination procedures. At the end of each targeted deployment period, the four, 1-L sample bottles will be capped and stored in a cooler at 0 to 6 °C until transport to the laboratory and archival pending compositing and analyses. The entire sediment trap solids samples will be analyzed. At the end of the final deployment period, in-line sediment traps and equipment will be removed from the stormwater systems.

#### **4.5.6 Flow Monitoring Methodology**

Pulsar Measurement Greyline Stingray 2.0 level-velocity loggers will be incorporated into the stormwater sampling program in the city outfall basins to continuously measure water levels and velocities. These parameters will be converted to flow and volume using the cross-sectional geometry of the flow in the pipe during the HVS event as well as during the entire wet and dry seasons. The conversion to flow will be made using Manning’s equation (Chow, 1959) with adaptations specific to flow in partially filled pipes:

$$Q = (1.49/n) A (R_h^{2/3}) S^{1/2}$$

where:

- Q = flow rate
- n = Manning's roughness coefficient
- A = cross-section area of the flow
- $R_h$  = hydraulic radius
- S = slope

It is expected that during sampling events the stormwater pipes will be flowing partially full. Flow calculations for partially full pipe flow are complicated by two considerations: (1) the equations for calculating the hydraulic radius ( $R_h$ ) are different depending on whether the pipe is flowing more than half full or less than half full, and (2) the Manning roughness coefficient must be considered to vary as a function of the ratio of depth of flow to diameter for the calculations to be accurate. Camp's method (Camp, 1946) will be used to determine the appropriate Manning roughness coefficient based on the depth of flow relative to the pipe diameter.

The loggers will be mounted on stainless steel plates and securely fastened to the bottom of the stormwater pipe using small (0.25-inch) stainless steel anchor bolts and nuts. The cable from the logger module to the probe will be fastened to the pipe using the same hardware and protected from high flows. If necessary, the cable will be shielded using a 1-inch flexible electric conduit. The module will be positioned near the top of the invert, directly beneath the manhole cover, to allow easy access for downloads and inspections. The logger module will be fitted with cable strap locations, which will be used to tie the module to the top ladder rung.

#### **4.5.7 Contingency Plans**

##### **4.5.7.1 HVS System Sampling**

The HVS system will target the optimal 200-L total volume collected at the average 1.5 L/min pump rate (target stormwater volume of 53 gallons). If the storm flow volume or flow period does not allow for attainment of this sample volume, but still meets the JSCS criteria for a qualifying storm, the sample will still be collected at an adjusted flow rate. The effect of pumping less than the optimal 200 L minimum through the HVS system will affect the achievable laboratory detection limit, although even with limited volume the detection limits for the HVS system samples will be well below those that can be achieved using conventional laboratory analyses. If river backflow is predicted to occur at the proposed HVS locations, the sampling will be conducted at the alternate locations (AAM107 in the M-1 outfall basin and AQQ104 in the M-3 outfall basin), HGL will target events expected to occur near low tide.

##### **4.5.7.2 Manual Grab Solids Sampling**

Manual stormwater solids grab samples will be collected if a minimum of 8 ounces of solids are present. If less than 8 ounces of solids are present, then alternative locations further upstream in the conveyance system will be inspected, and the location with at least 8 ounces of sediment will be sampled. Alternative locations without at least 8 ounces of sediment present will not be sampled.

#### **4.5.7.3 In-Line Sediment Trap Sampling**

Each location includes four sample bottles, which increases the anticipated mass of collected stormwater solids compared to less bottles. If sample volume is limited, analysis of the ROD focused COCs (PCBS, dioxins/furans, OCPs) will be prioritized over the remaining ROD COCs.

#### **4.5.7.4 General**

In instances where ROD COCs and conventional parameters are targeted for analysis, but the volume of stormwater solids or stormwater is limited, then analysis of PCBs, dioxins/furans, and OCPs will be prioritized over other COCs with metals analysis completed on any remaining solid or liquid. In these cases, the HGL sampling and analysis coordinator, in consultation with the HGL PM, will provide the laboratory with a list of the analytical priorities for that specific sample location.

### **4.6 HABITAT CONDITIONS SURVEY**

A reconnaissance-level habitat conditions survey will be performed to address data gaps related to characterization of aquatic resources within the shallow nearshore zone and ecological conditions along the banks as they pertain to ecological benefits imparted to the adjacent aquatic resources. A field reconnaissance survey will be conducted of the entire shoreline included within the SIB Project Area to qualitatively document both bank conditions and substrate conditions within the shallow nearshore zone. The shoreline survey will describe present-day conditions around the shoreline and riverbanks and provide consistency in the quality and applicability of the data. The habitat survey will be integrated with and conducted as part of the riverbank physical inspection and erodibility evaluation described in Section 5.3.4.

### **4.7 SAMPLE HANDLING AND CUSTODY**

Sample handling and custody includes the field-related considerations connected with selecting sample containers, preservatives, allowable holding times, and analyses requested. To verify the samples are traceable, field staff will follow the procedures for sample handling and custody procedures as described in the UFP-QAPP Worksheets #26 and 27.

#### **4.7.1 Field Sample Preservation and Containers**

See UFP-QAPP Worksheets #19 and #30 Sample Containers, Preservation, and Hold Times.

#### **4.7.2 Field Sample Identification, Tracking, and Labeling**

Each sample collected will be assigned a unique sample ID number and will be collected from a unique station location. Several samples can be collected from a single station.

##### **4.7.2.1 Identification**

Sample ID will be based on waterbody, media, and sample location as follows:

#### *4.7.2.1.1 Surface Sediment Sample Nomenclature*

Sample nomenclature for surface sediment grid sampling will be developed to relate samples to the grid pattern and sample interval. Samples will be uniquely identified as follows:

##### Water Body-Grid Node-Sample Depth-Date

where:

- Water Body = A predesignated water body acronym, such as “SIB” for Swan Island Basin.
- Grid Node = Alphanumeric code for each node. Letter “A” to “T” identify up/down river locations, and numbers “1” to “7” identify cross-river locations. (e.g., J5).
- Sample Depth = The actual depth interval of the collected sample (top## - bottom##). For example, if the penetration depth of the grab sampler is 27 cm, the sample ID will include "0-27".
- Date = The date of sample collection will be added to the sample ID in the following month, day, year format: MMDDYYYY.

For example, a surface grab sample from grid node J5, where the grab sampler penetrated to a depth of 27 cm and was collected on October 15, 2021, would have the sample ID: SIB-J5-0-27-10152021.

#### *4.7.2.1.2 Stream In-Channel Sediment Sample Nomenclature*

This nomenclature will also be used for DRET and in-line sediment trap sampling. Each in-channel stream sediment sample will be uniquely identified as follows:

##### Water Body-Sed-Location-Date

where:

- Water Body = A predesignated water body acronym, such as “SIB” for Swan Island Basin.
- Sed = Sediment sample.
- Location = A predesignated location described, such as “MP1” for Mid-Point Station 1.
- Date = The date of sample collection will be added to the sample ID in the following month, day, year format: MMDDYYYY.

#### *4.7.2.1.3 Subsurface Sediment Sample Nomenclature*

Sample nomenclature for subsurface samples will be developed to relate samples to sample type, location, and sample interval. Samples will be uniquely identified as follows:

##### Water Body-AA-Location-Sample Depth-Date

where:

- Water Body = A predesignated water body acronym, such as “SIB” for Swan Island Basin.
- AA = Sample type, SC for sediment core or SF for SedFlume.
- Location = A predesignated location described, such as “MP1” for Mid-Point Station 1.
- Sample Depth = The actual depth interval of the collected sample in ft (top## - bottom##). For example, if the penetration depth of the grab sampler is 0 to 1 ft, the sample ID will include "0-1".
- Date = The date of sample collection will be added to the sample ID in the following month, day, year format: MMDDYYYY.

For example, a sediment core sample from grid node JS for the 0- to 1-ft interval collected on October 15, 2021, would have the sample ID SIB-SC-MP1-1-2-10152021.

#### *4.7.2.1.4 Geotechnical Sediment Sample Nomenclature*

Each geotechnical and CPT sample will be uniquely identified as follows:

Water Body-Geo-Location-Date

where:

- Water Body = A predesignated water body acronym, such as “SIB” for Swan Island Basin.
- Geo = Geotechnical sample.
- Location = A predesignated location.
- Date = The date of sample collection will be added to the sample ID in the following month, day, year format: MMDDYYYY.

For example, a cone penetration sample from CPTW-5 collected on October 15, 2021, would have the sample ID SIB-Geo-CPTW7-10152021.

#### *4.7.2.1.5 Stormwater Sample Nomenclature*

Each stormwater sample will be uniquely identified as follows:

Water Body-SW-Location-Date

where:

- Water Body = A predesignated water body acronym, such as “SIB” for Swan Island Basin.
- SW = Stormwater sample.

- Location = A predesignated location.
- Date = The date of sample collection will be added to the sample ID in the following month, day, year format: MMDDYYYY.

For example, a sample from WR-437 collected on October 15, 2021, would have the sample ID SIB-SW-WR437-10152021.

#### *4.7.2.1.6 QC Sample Nomenclature*

Field QC samples will be performed using the following protocols: (1) matrix spike (MS) and matrix spike duplicate (MSD) samples will be identified by using the parent sample location ID with “MS” and “MSD” appended, and (2) field duplicates, equipment blanks, and trip blanks will be identified as “BB##-MMDDYYYY,” where “BB” will be for the QC sample type: field duplicate (FD), equipment blank (EB), or trip blank (TB); “##” will represent the consecutive sample number (01, 02, 03, etc.); and “MMDDYYYY” will represent the month, day, and the four digits of the year that the sample was collected.

For example, the third FD collected during a sampling activity on October 15, 2021, would have the sample ID FD03-10152021.

The field logbook will include the parent or sample location ID that is associated with the field QC samples. All QC samples will have “1200” as the collection time.

#### **4.7.2.2 Field Sample Tracking**

See Worksheet #6 in the UFP-QAPP for a discussion on tracking field samples.

#### **4.7.2.3 Field Sample Labeling**

Sample labels will include the information presented in Worksheets #26 and #27 Sample Handling, Custody, and Disposal of the UFP-QAPP.

#### **4.7.3 Sample Chain of Custody**

The CoC record is employed as physical evidence of sample custody and control. This record system provides the means to identify, track, and monitor each individual sample from the point of collection through the final data reporting.

See UFP-QAPP Worksheets #26 and #27 Sample Handling, Custody, and Disposal for information on sample custody requirements, including procedures on packaging, shipment, and delivery to the laboratory.

### **4.8 FIELD SUPPLIES AND EQUIPMENT**

The FTL will prepare field supply and equipment lists at least one month in advance of planned field activities. The field team will review the HASP for an additional list of required health and safety supplies. Field equipment will be inspected to ensure working condition before commencing

fieldwork. Analytical instrument testing, inspection, maintenance, setup, and calibration will be conducted in the field in accordance with the requirements identified in the SOPs and manufacturer instructions. In addition, each of the specified field analytical methods provides protocols for proper instrument setup and tuning, and critical operating parameters. Instrument maintenance and repair will be documented in maintenance log or record books.

#### **4.8.1 Calibration**

Equipment used at the site will be calibrated according to the manufacturer specifications, if necessary. Field equipment will be calibrated before the start of each workday and calibration data will be documented in the Daily Equipment Calibration Log Form (Appendix B). Instrument drift from prior calibration will be recorded in the field logbook. Procedures for PID calibration are provided in SOP A-2 PID Screening and Calibration Procedures (Appendix A). Equipment found to be damaged, inoperable, or out of calibration will not be used until the discrepancy is corrected and verified by the field task manager or designee. As necessary, a detector sensitivity or test grid may be used to test the functionality before daily use, and results documented accordingly. Once equipment has been used, it will be maintained following manufacturer recommendations, and at intervals recommended by the manufacturer.

#### **4.8.2 Maintenance**

Maintenance and troubleshooting of the instruments to be used for field parameter measurements will be completed, as described in the manufacturers' instruction manuals and the SOPs for their use. Used calibration fluids will be containerized and disposed of as described in the Waste Management Plan (Appendix C).

### **4.9 DECONTAMINATION**

Procedures for decontamination will be implemented to avoid cross contamination of samples that are submitted for chemical analyses. Decontamination procedures will meet the requirements contained in SOP 411.02 Sampling Equipment Cleaning and Decontamination.

Final decontamination of equipment used to collect the samples will be required prior to equipment demobilization from the site. This decontamination step is required to prevent contaminants from being transported off site. The same procedures used for decontamination between sample locations will be used during final decontamination.

#### **4.9.1 Hand Sampling Tools**

Non-disposable sampling and testing equipment exposed to the sample medium will be decontaminated to prevent cross contamination between sampling points. For recasts at a location, the grab sampler or other recasting equipment will be rinsed/sprayed with river water until solid material is removed.

Reusable sampling equipment will be decontaminated between stations. The decontamination steps will include an initial rinse with vessel riverwater to dislodge particles, a scrub with brush and Alconox™ or other phosphate-free detergent, and then a rinse with deionized water. In the event of excessive oily/tar residue, the sampling equipment may be scrubbed using a fast-

evaporating distillate of petroleum (such as toluene or xylene) or Simple Green™ until all visual signs of contamination are absent. If used, the distillate of petroleum product will not include use of oily paint thinners. Following removal of the oily/tar residue, the equipment will be rinsed with Alconox™ and distilled water to ensure the removal of the petroleum distillate. If NAPL is encountered and a solvent rinse is conducted, a field equipment wipe blank may be collected after decontaminating the equipment. This process will be documented in the field logbook for tracking purposes. The wipe blank can be archived (frozen) for future analysis if cross-contamination is suspected. Sampling spoons and bowls will be covered with aluminum foil until use (dull side down). Core tubes and core catchers will be washed in a similar manner.

Gloves will be replaced before and after handling each sample or conducting decontamination procedures. Field equipment decontamination dates and times will be noted in the logbook.

#### **4.9.2 Drilling Equipment**

The following is the standard procedure for field cleaning augers, drill stems, rods, tools, and associated equipment. This procedure does not apply to soil samplers, well casings, well screens, or other equipment used to obtain samples for chemical analyses.

- Wash with tap water and soap using a brush, if necessary, to remove particulate matter and surface films. Steam cleaning (high-pressure hot water with soap) may be necessary to remove matter that is difficult to remove with the brush. Drilling equipment that is steam cleaned should be placed on racks or sawhorses at least 2 ft above the floor of the decontamination pad. Hollow-stem augers, drill rods, etc., that are hollow or have holes that transmit water or drilling fluids, should be cleaned on the inside with vigorous brushing.
- Rinse thoroughly with tap water.
- Remove from the decontamination pad and cover with clean, unused plastic. If stored overnight, the plastic should be secured to ensure that it stays in place.

If drilling equipment is contaminated with oily/tar that cannot be decontaminated with an Alconox™ detergent rinse, a concentrated Alconox™ rinse will be attempted. If that approach is still unsuccessful, then a fast-evaporating distillate of petroleum (such as toluene or xylene) will be used to remove the oily/tar residue. This distillate of petroleum product will not include use of oily paint thinners. Following removal of the oily/tar residue, the equipment will be rinsed with Alconox™ and distilled water to ensure the removal of the petroleum distillate.

#### **4.10 WASTE MANAGEMENT PLAN**

See Appendix C for the Waste Management Plan. The Waste Management Plan describes the wastes that will be generated during performance of the field activities and provides details on how the waste will be handled, transported, and disposed. The Waste Management Tracking Log Form can be found in Appendix B.

*This page was intentionally left blank.*

## **5.0 ENGINEERING FIELD ACTIVITIES**

The following sections provide overviews on field activities intended to provide data for engineering purposes that will feed directly into the RD. Field activities will be performed in accordance with statements of work developed for specialty subcontractors (Appendix D), as well as the vertical and horizontal control guidelines outlined in Section 7.0.

### **5.1 BATHYMETRY AND TOPOGRAPHY**

Accurate elevation data is required for many purposes on the project. Per the data gap analysis, new multi-beam bathymetric survey data is required for the project site. Multi-beam bathymetric survey data should cover the entire project area to the extent feasible given the presence of some obstructions in the SIB. Also, per the data gap analysis, new topographic survey data will not be collected during the PDI as existing LiDAR data and new laser scan data provide sufficient upland elevation information for pre-design studies and sitewide topographic surveying is currently unnecessary. Topographic data will be further collected later in areas where necessary to support detailed engineering design. Multi-beam bathymetric survey data will be acquired by a subcontractor using a subcontractor vessel in 1 or 2 days with Mott MacDonald oversight. Mott MacDonald staff will accompany the surveyors for key portions of the survey activity and observe instrument calibration, real-time data collection, and discuss key elements of the vessel positioning and data calibration and correction. Figure 5-1 shows the proposed area for collection of multi-beam bathymetric survey data.

### **5.2 DETECTION OF EXISTING BURIED UTILITIES AND DEBRIS**

Five separate methods will be utilized to identify potential buried utilities and debris that may affect Remedial Action. Two of these methods are described in other sections: 1) a multi-beam bathymetric survey (see Section 5.1) will be performed to identify objects on the seabed over which a vessel can pass, and some below-water parts of structures/debris; and 2) an MTLIS (see Section 5.3.3) will be performed to locate above-water debris and nearshore marine structures. This section focuses on three additional types of field surveys that will allow the project team to identify and locate objects in water, both above and below the riverbed:

- sub-bottom survey,
- magnetometer survey, and
- side-scan sonar.

This data will be acquired by a subcontractor using a subcontractor vessel in 1 or 2 days with Mott MacDonald oversight. Mott MacDonald staff will accompany the surveyors for key portions of the survey activity and observe instrument calibration, real-time data collection, and discuss key elements of the vessel positioning, and data calibration and correction. Data will be collected along transects shown in Figure 5-2 at a minimum, with additional transects and focused data collection around detected objects.

### **5.3 SHORELINE/OVERWATER STRUCTURE INSPECTION AND CONDITION ASSESSMENT**

An overwater structures field inspection and condition assessment will be performed in general accordance with the American Society of Civil Engineers (ASCE) *Waterfront Facilities Inspection and Assessment Manual of Practice*, ASCE Manual of Practice No. 130 (ASCE, 2015). The inspections will follow a two-step process: first, a screening-level inspection will be performed on overwater structures via site walk and boat tour; then, a select number of structures will be chosen to receive a more in-depth dive inspection. In addition, a boat-mounted laser scan survey will be performed to locate and document the shoreline, in-water emergent debris, and nearshore marine structures. The condition of each structure will be assessed, and findings will be summarized in accordance with ASCE Manual of Practice No. 130 in the PDI Evaluation Report (see Section 12.0). A summary of the inspections and additional laser scan survey is provided in the following sections.

#### **5.3.1 Screening Level Structural Inspections**

A screening-level visual inspection of readily accessible, main structural systems components and fender piles will be conducted to be able to form an engineering opinion on the general condition of each structure and confirm as-built layout and structural details. The screening inspection results will identify those structures that are recommended to receive a dive inspection and to make further inspection recommendations.

The inspections will be conducted above the deck of each structure first on foot, then via boat to observe the above-water components beneath the deck. Photographs, video documentation, and physical and/or electronic field notes from this effort will be collected and provided with inspection reports. Noticeable signs of distress and deterioration, focusing on main structural system components, will be noted and, where possible, an estimate of remaining capacity will be made. Main structural system components will include prestressed concrete, steel pipe, or treated timber pile; steel sheet pile cellular structures; reinforced concrete, timber, or steel pile caps, beams, and joists; reinforced concrete or timber decking; structural bracing; and fender piles.

Should repairs or structural modifications be required on a given structure to achieve the RD, a repair-level inspection will be needed during the final design phase to confirm precise quantities and deterioration locations that require repair.

#### **5.3.2 Dive Inspection of In-Water Structures**

Selected in-water and overwater structures will be inspected by a dive team. The structures selected for a dive inspection will be based on the results of the screening-level inspections and preliminary analysis of the impacts of the Remedial Action on the structures. For structures anticipated to be impacted by the Remedial Action, a top to bottom inspection will be conducted.

To avoid affecting facility operations during the inspection, communication with the local facility operations team during the inspection period will be maintained. Points of contact (routine and emergency) will be established prior to the start of diving operations for expected vessel movements while the team is on site. Daily contact at the beginning, during, and end of the

inspection day will be maintained to confirm required facility operations individuals are aware of intended diving operations in the vicinity of the overwater structure. Dive flags will be displayed, and appropriate very high frequency radio channels will be monitored. A marine traffic radio will be used to hail vessels approaching too close to the dive operations.

The inspection will consist of a visual and tactile structural inspection (Level I) of the entire visible surface from channel bottom to the top with particular attention given to observed areas of deterioration or apparent distress. The inspection will also include Level II (in-depth visual) inspection of 10% of the members by removing a 1-ft-high band or 1-ft-square area of biological growth around the entire circumference of the pile/member at the channel bottom, mid-height, and waterline. A Level III (nondestructive testing) inspection will be performed on up to 5% of each timber and steel member to detect hidden or interior damage. Additional information on this activity will be provided by the subcontractor and added as an SOW to Appendix D and/or addenda to the HASP.

### **5.3.3 Mobile Terrestrial LiDAR Survey of Existing Structures, Debris and Shoreline**

An MTLS survey or boat-mounted laser scan survey will be performed to locate and document the shoreline, in-water emergent debris, and nearshore marine structures. This data will be acquired by a subcontractor using a subcontractor vessel in 1 or 2 days with Mott MacDonald oversight. Mott MacDonald field sampling staff will accompany the surveyors for key portions of the survey activity and observe instrument calibration, real-time data collection, and discuss key elements of the vessel positioning, data calibration and correction, and final processing. Data will be collected along the shoreline shown in Figure 5-3 at a minimum, with additional focused data collection around important structures and concentrations of marine debris.

## **5.4 HYDRODYNAMICS AND SEDIMENT DYNAMICS**

The purposes of field sampling hydrodynamic and sediment dynamics data are to generate data necessary to evaluate recontamination potential, and to demonstrate stability/persistence of the remedy under both river hydrodynamics and anthropogenic hydrodynamics (e.g., propeller wash). Field data collected is used to either directly characterize the site, or is used as input to, or validation of, numerical modeling tools.

### **5.4.1 Current Velocities and Water Levels**

Current velocities will be measured for the purposes of characterizing the site and refining the conceptual site model, as well as for input to, and validation of, numerical modeling tools (hydrodynamics and sediment transport models). Current data provides the magnitude and direction of flow throughout the water column at a given time and location. Current velocities and low-frequency water levels (i.e., tides) will be measured using a combination of both boat-mounted, and two (2) bottom-mounted, acoustic doppler current profilers (ADCPs). This data will be acquired by a subcontractor using a subcontractor vessel during deployment and/or recovery of bottom-mounted instruments with Mott MacDonald oversight. The bottom-mounted sensors will collect data for two (2) consecutive 30-day periods, with a mid-program recovery, onboard data review, and redeployment to ensure data quality. Mott MacDonald staff will accompany the subcontractor for key portions of the deployment and measurement activity and observe instrument

calibration, real-time data collection; and discuss key elements of the vessel positioning, and data calibration, and correction. Proposed deployment locations of the bottom-mounted ADCPs and proposed transects for collecting boat-mounted ADCP data are shown in Figure 5-4. Lateral transect locations were chosen to measure alongshore currents and eddying effects, while avoiding active vessel mooring locations. Longitudinal transects were included to capture cross-basin currents that likely occur in some locations due to eddying effects. It is understood that currents are likely quite small within the interior of the basin and demonstrating this is an important element of validating the SIB conceptual site model.

#### **5.4.2 Wind-Waves and Boat Wakes**

High-frequency, free surface elevation measurements will be collected in the SIB Project Area to assist in characterizing wind waves and boat wakes. This data will be acquired by a subcontractor using a subcontractor vessel during deployment and/or recovery of pile-mounted instruments with Mott MacDonald oversight. Four (4) pile-mounted sensors will collect data for two (2) consecutive 30-day periods, with a mid-program recovery, onboard data review, and redeployment to ensure data quality. Mott MacDonald staff will accompany the subcontractor for key portions of the deployment activity and observe instrument placement, data testing, and recovery, and discuss final data evaluation. Wind-wave and boat-wake free surface elevation measurements will be collected at the approximate locations shown in Figure 5-4, depending on availability of suitable structures upon which to mount the sensors and permission from the owners/operators.

#### **5.4.3 Suspended Sediments**

Suspended sediment sensors will be deployed by a subcontractor using a subcontractor vessel at the same time as, and co-located with, the bottom-mounted ADCPs described in Section 5.4.1 and shown in Figure 5-4. Suspended sediment measurements are a low-cost way to determine the amount of suspended solids moving in the water column over time which supports recontamination evaluation and understanding of general sediment dynamics. Deployment, recovery and redeployment, and final recovery activities will also be identical to those performed for the bottom-mounted ADCPs. As with the ADCPs, the two (2) bottom-mounted turbidity sensors will collect data for two (2) consecutive 30-day periods, with a mid-program recovery, onboard data review, and redeployment to ensure data quality.

A logging Conductivity, Temperature, and Depth (CTD) Sonde equipped with a turbidity sensor will be mounted on the ADCP platforms and oriented such that the sensor portion or the CTD is near the level of the first ADCP data bin or at least near the same distance from the bottom as the ADCP head. The CTD will collect sensor data concurrently with the sampling period of the ADCP. A third CTD will be used to collect water quality profiles that include optical turbidity for at least three (3) ensembles during the current profiling at each bottom mount for through column correlation with back-scatter data. CTD profiles will be collected concurrently with water samples. The purpose will be to collect data throughout the water column to provide a vertical variation profile to supplement the near-bottom optical backscatter point sensor (OBS)/turbidity measurements. Note that due to equipment shortages and availability, an infrared turbidity OBS sensor may be used in place of an optical turbidity CTD.

To assist with data correlation and quality checks, approximately 500 milliliters (mL) to 1,000 mL of water will be collected for laboratory analysis of turbidity and TSS based on the laboratory's requirements. A maximum analysis of up to 10 water samples will be collected following the first deployment of the ADCP platforms, and up to 10 water samples will be collected following the second deployment. A water grab sampler will be used to collect a water sample within the first sample bin (estimated to be approximately 1 meter from bottom) near both ADCP stations during an ensemble recording event. Turbidity from these samples will be recorded on the boat upon recovery using a handheld turbidity meter then processed for transport to a laboratory for testing (turbidity and TSS only).

Additional water samples shall be taken at random locations along the proposed ADCP transects following a CTD profile at the close of the transect at an area and depth indicating varying backscatter on the ADCP real-time display. Water samples will be analyzed by a contract laboratory for TSS, by EPA Method 160.2 and suspended solids concentration (SSC) analytical method, ASTM D 3977-97, Standard Test Method for Determining Sediment Concentration in Water Samples (ASTM, 1999). Results of laboratory analysis and details of the sample collection will be provided with the PDI Evaluation Report. Laboratory water samples will be collected concurrent to the first deployment and service deployment event only.

Prior to deployment, turbidity sensors will be pre-calibrated using a nominal range concentration turbidity standard for the site. The position of the turbidity sensor will be set such that it is within the first ADCP bin (from bottom). Water samples for TSS/SSC measurements will be collected at the same level as the turbidity measurement and near the instrument location. Pre-calibration of the turbidity sensors will be standardized using a two-point calibration with distilled water and a high concentration turbidity standard to set the internal offset and scale of the OBS or alternate turbidity sensor. During the TSS calibration, short-term averages (as provided by logger) will be recorded with the OBS/turbidity sensor in a thoroughly mixed container of site sediment collected within the sediment traps, or those collected using a small grab sampler (backup) and distilled water. Three to five sediment concentrations, ranging up to 4.0 g/L will be used to develop a calibration curve. This calibration will likely be represented by a non-linear second or third order polynomial curve with a specific calibration for each sensor. During post processing, the stored data logger values (in nephelometric turbidity units, counts or millivolts) will be processed with the developed calibration equations to produce SSC values for each averaged field measurement.

## **5.5 POREWATER UPWELLING LOCATION SURVEY**

Per the PDI, this will consist of manually deploying a Trident Probe, a multi-sensor sampling device, to measure temperature and specific conductance contrast between porewater, or interstitial water, in surface sediment and overlying surface water at discrete stations to identify potential upwelling zones along transects within the SIB Project Area. Appendix A contains SOP A-8 for the Trident Probe. Identification and mapping of locations within the SIB Project Area where upward porewater migration occurs is needed to address data gaps. Figure 5-5 is a map of proposed transects to evaluate porewater upwelling locations where capping may not be effective or, alternatively, locations where adjustments to engineered cap design may be required to prevent breakthrough of COCs through the cap due to upward migration of porewater through contaminated sediments below the cap.

The survey will be conducted on fifteen 800-ft-wide transects across SIB (with up to 10 stations each where no permanent structures are present) and two 400-ft-wide transects at the head of SIB (8 stations) for a total of up to 158 stations. The Trident probe measurements are planned to be collected at a rate of 15 stations per day. The Trident probe records temperature and specific conductance measurements every 5 seconds; the reported measurements are the average over a 30-second interval.

Measurements may deviate from the transects to map those areas with the largest temperature and conductance gradients between sediment and overlying surface water. Measurements may deviate from the proposed transect lines if a strong contrast in surface water and porewater conductivity measurements is recorded in one area along a transect to delineate the extent of that contrast on and around the transect line area and to quantify variability within the potential upwelling zone. The stronger the difference in measurements, the more measurements will be collected in that area to map the extent of the upwelling zone(s). These additional stations will be within 50 ft of the previous station. In addition, deviations from proposed station locations may occur if the substrate is too hard to manually drive the Trident Probe into the sediment, vessels or other over-water features present during the survey.

The timing of the investigation will be planned during the time of the year when the river surface elevations are dropping, has less tidal fluctuations (neap tides), temperature contrasts between surface water and groundwater are greatest, and seasonal groundwater elevations are higher than river elevations. Figure 4-1b of the PDI Work Plan shows groundwater elevations relative to river elevations for those wells closest to the basin versus the river channel. Some groundwater elevations consistently plot close to river elevations, reflecting high connectivity with the river, and, as a result, are influenced by mean river level and potentially the tides. Groundwater elevations were higher than river elevations in December 2001, March 2002, July 2002, October 2002, March 2003, September 2003, December 2003, January 2005, October 2005, September 2006, October 2006, January 2007, and September 2007. In addition to a comparison of groundwater elevations relative to river elevations, the timeframe for discharge mapping is also related to a temperature signal difference between groundwater and surface water. This difference is generally stronger during the winter (groundwater warmer than surface water) and summer (groundwater cooler than surface water) and weaker during transition periods of fall and spring based on Gravity Marine and Coastal Monitoring Associates professional experience on rivers in the Pacific Northwest. For example, in late February 2022, river temperatures were 6 to 7 degrees Celsius, and are expected to provide a good contrast with groundwater temperatures (estimated to be between 12 and 15 degrees Celsius [Bridgewater, 2020]). Also in late February 2022, discharge and gauge heights were low (below 25<sup>th</sup> percentile) with low river conditions (<https://waterdata.usgs.gov/nwis/uv?14211720>). The survey period was selected to correspond as closely as possible to neap tide conditions when tidal fluctuations are relatively small (~2 ft). The subsurface probe depth was also selected to be at 18 inches, deep enough to be minimally affected by tidal fluctuations. As a result, the upwelling survey is proposed for February and March 2022.

The upwelling survey results will be overlaid on proposed cap areas and possibly used to identify future collection stations for quantitative measurements of seepage rates in proposed cap areas for cap modeling. The need for porewater analyses will be assessed after the delineation of upwelling zones and may occur as part of the RD for cap design.

## **6.0 FIELD DOCUMENTATION REQUIREMENTS**

This section defines the specific records and data that must be maintained for each field activity to ensure that samples and data are traceable and defensible. At a minimum, data will be collected to meet EPA requirements for electronic data deliverables (EDDs) including specific data needs and reporting for EQUiST™. The specific requirements are discussed in the Data Management Plan (DMP) located in Section 9.0.

### **6.1 FIELD LOGBOOK**

A written record of sampling activities and field observations will be maintained in a bound, water-resistant field logbook with consecutively numbered pages (or suitable tablet). Entries will be legibly written in black or blue, indelible ink. Entry errors will be corrected by drawing one solid line through the incorrect entry, followed by the user's initials and date, with the correct information entered in proximity to the erroneous entry. At the end of each workday or task, the individual making the entries will sign and date the field logbook. Factual and objective language will be used. Entries will be complete and accurate enough to allow reconstruction of each field activity. Activities should be recorded contemporaneously. When not in use, the logbook will be stored in the permanent project file. After completion of the sampling activities, the field logbooks will be kept in the custody of the HGL PM or subcontract team member's PM. Additional guidance is provided in SOP 300.04 (Appendix A).

Information recorded in field logbooks will include, but not be limited to sampling time, weather conditions, unusual events, and field measurements. Field logbooks should also contain qualitative or semi-qualitative information on sample conditions such as odor and color. Deviations from SOPs or guidance documents will be recorded in the field logbook.

### **6.2 CALIBRATION LOGS**

Record equipment calibration, including instrument type and serial number; calibration supplies used; calibration methods and calibration results; and date, time, and personnel performing the calibration in the Calibration Log field form (Appendix B). Calibrate equipment used during the investigation daily, at a minimum, in accordance with manufacturer recommendations.

### **6.3 PHOTOGRAPHIC LOGS**

Digital photographs will be taken in the field to document representative sampling locations, collected samples, site conditions, and other salient site-related observations. Photographs will be date stamped and should be provided by using a digital camera or a video camera capable of recording the date on the image. Details of each photograph should be recorded in the logbook with the location of the photographer (including GPS coordinates), direction the photograph was taken, the subject of the photograph, and its significance (i.e., why the picture was taken). Where appropriate, the photograph location, direction, and subject also should be shown on a site sketch.

A photographic log will be kept to record the date the photograph was taken, location, photo ID number, brief photographic description, direction the photographer is facing (if appropriate), and, for example, if sheen was produced during collection of sediment samples. Photographs and

relevant log information will be downloaded onto a field computer on a regular basis for upload to SharePoint, in accordance with data management requirements. Additional guidance is included in SOP A-3 Sampling Photography (Appendix A).

#### **6.4 OTHER DOCUMENTATION**

In addition to the physical and/or electronic field notes, activity-specific forms such as for soil and sediment sampling, will be completed. Field sampling activity forms are planned to be generated through EQUIS™. Field forms will need to be routinely scanned for upload to SharePoint, in accordance with data management requirements. These forms are included in Appendix B.

#### **6.5 ENGINEERING FIELD INSPECTION DOCUMENTATION**

Engineering inspection activities will be performed, documented, and stored digitally within the Mott MacDonald SmartInspect system. The system will include activity-specific digital forms to be completed via waterproof smart device (iOS or Android), with field geolocation of photographs and basic measurements. Field logs compiled using SmartInspect are real-time uploaded to an online database in standard SQL server or other database formats. The stored database formats provide immediate use in ArcGIS, CSV or other standard formats and field progress and reports will be monitored in real-time from the office during the inspection activities via the online ArcGIS platform. The engineering field inspection documentation will follow SOP 300.04 in principle, but with digital logbooks and automatic database incorporation.

## **7.0 HORIZONTAL AND VERTICAL CONTROL**

Station positioning and vertical control will be performed as outlined in SOP A-7 Horizontal and Vertical Control (Appendix A). A differential GPS unit will be used to confirm the horizontal sampling locations to an accuracy of 1 to 2 meters. The differential GPS accuracy will be confirmed each morning and evening to a known land-based survey point. Confirmed station locations will be recorded to the nearest whole ft in NAD83 Oregon State Plane Coordinate System, Oregon North Zone.

### **7.1 POSITIONING, HORIZONTAL, AND VERTICAL CONTROL**

Vertical control will be established using an on-board fathometer or lead line to measure depth to mudline at sample locations. A bar check will be conducted daily prior to sampling. This will be done by lowering a metal plate at a known distance below the sonar and recording the value. The depth will be analyzed for accuracy based on the draft of the sonar below the waterline. Draft values will be input into the survey navigation software HYPACK. This allows for static offsets to be applied to real-time depth data and corrected for accurate depth readings. Any adjustments in the draft value will be measured and input directly in the hardware configuration of the HYPACK survey software prior to sampling.

Water depths will be converted to elevations in ft NAVD88 based on the river stage at the time of sampling as recorded at the Morrison Street Bridge located at RM 12.7. The gauge reports a value that is 0.3 ft above CRD. CRD depths will be converted to NAVD88 elevations using the USACE conversion for RM 7.5 to Broadway Bridge: CRD is 5.28 ft above the NAVD88 elevation at RM 9.7.

### **7.2 NAVIGATION AND STATION POSITIONING**

The proposed sampling locations for sediment activities, geotechnical, riverbank, stormwater, and stormwater solids are presented in Figures 4-3 through 4-8, and Tables 4-2 through 4-6. Surface sample station coordinates are not listed but will be collected from three locations within a 25-ft radius of the target sediment core stations (see Figure 4-3). The standard projection method to be utilized during field activities is Horizontal Datum: NAD83, State Plane Coordinate System, Oregon North Zone. The datum that will be utilized to record vertical positioning is NAVD88. Finalized station coordinates will be pre-loaded into GPS units to facilitate proper location of the sample stations by the field teams.

Gravity Marine will use differential GPS hard-wired to the vessel for horizontal positioning. Two points, provided in Table 7-1, represent known benchmarks surveyed in 2018 by David Evans. These will be used for daily check-ins by boat to assess GPS accuracy over the course of the sediment sampling work. The positioning objective is to determine and record the horizontal field positions of sampling station locations to within  $\pm 5$  ft.

#### **7.2.1 Positioning at Sediment Sample Stations**

For the power-grab and vibracore sampling, the marine subcontractors, in coordination with the on-board sampling staff, will position the support vessel and power-grab sampler as close as

practical to the target sample station and will anchor the vessel in place during sample collection. The latitude and longitude coordinates of the sample will be obtained by a GPS unit positioned directly above the sampling instrument when the equipment is on the river bottom. Vertical positioning is required to establish the elevation of the mudline at the sampling stations. While the sampling device is in place at the sampling station, depth to mud line will be measured using a fathometer on the vessel before or during the sampling. A lead line (or pole), equipped with a flat plate to better sense soft sediments, is typically used to verify the readings on the vessel's depth finder. Vertical measurements to the mudline will be recorded to the nearest 0.1 ft below the water surface. Additionally, a tide board will be installed in the SIB Project Area, coupled with a surface stilling well, for direct readings of water surface elevations in NAVD88. Water surface elevation readings will be recorded periodically while sampling and used in combination with water depth readings to calculate mud line elevations at sample stations. GPS precision and accuracy will be confirmed each morning and evening at a fixed surveyed benchmark (to be determined), approved by EPA prior to initiating the sediment sampling work, and then recorded.

### **7.2.2 Positioning at Geotechnical Sample Stations**

For geotechnical soil sampling, northing and easting coordinates will be obtained during field activities using either a hand-held or rod-mounted GPS unit. For over-water sampling, station positioning from the sampling vessel will be accomplished using GPS equipment capable of sub-foot accuracies, recognizing that station accuracy may be affected by satellite positioning and obstructions, such as the railroad bridge, large vessels, and heavy cloud cover. For sampling stations, the sampling staff will record the coordinates for each sample location on the field forms. Difficulties in achieving satellite coverage will be noted in the field logbook.

## **8.0 QUALITY CONTROL**

### **8.1 CHANGE MANAGEMENT**

Changes to the sample stations and methodologies described in this FSP may be required during the field program. The protocols for change management, discussed in this section, will be applied to keep the project moving forward smoothly and efficiently.

#### **8.1.1 Field Decisions and Documentation**

Field teams will report field condition-driven deviations from the FSP to the FTL for consultation and determination of the appropriate response. This category of field changes includes moving a sample station due to obstacles or refusal, modifying target depths or acceptable sample recovery at core locations, and other routine field decisions that are not uncommon in a large sediment investigation field effort. The decision-making process for documenting field change will require 1) verbal communication with EPA to initially discuss the situation and possible solutions, and 2) written documentation of the change. When these conditions arise, the experienced field team and FTL will use best professional judgment to determine the appropriate course of action by first notifying the PM, who will then notify the appropriate EPA contact (or their designee) of the proposed modification in scope for EPA approval. Changes to the FSP will be documented and approved in the form of a field change request form (unless already approved orally by EPA in the field, in which case the oral approval will be documented in writing in the field change request form and daily report).

QA/QC procedures and sample requirements are detailed in the UFP-QAPP Worksheet #12. Field duplicates and other field QC samples, such as temperature blanks and rinsate blanks, will be collected as outlined in the project UFP-QAPP. Rinsate blanks will be collected by pouring deionized water over the sampling spoons and core tubes (if a liner is not used) after field decontamination.

#### **8.1.2 Project Management and EPA Decisions**

Some issues that deviate from the FSP, or other project plans, may require the decision-making process to be elevated to the HGL PM. These are deviations that fundamentally modify the project approach and put the ability to meet project objectives at risk. Once elevated to the HGL PM these issues would require resolution before work could continue. This category includes encountering conditions that significantly change the conceptual site model. Issues that require involvement and approval of the HGL PM and EPA also include significant safety concerns that require work to stop to make corrective actions. See the HASP for more information on project safety protocols.

## **8.2 ANALYTICAL REQUIREMENTS FOR FIELD QUALITY CONTROL**

Field data will be recorded in the field on data forms and in logbooks that the FTL will review at the end of each field day. The review will include ID of values outside of reasonable ranges and completeness. In addition, the FTL will download electronic files (GPS and digital photographs) at the end of each field day to ensure there are no data collection problems and that the data that

was to be recorded at each reach was obtained. The task manager will provide further review (QA/QC) of the field data logbooks, forms, and electronic files prior to transmittal to HGL.

Field QC samples will consist of FDs, MSs, MSDs, TBs, and EBs. Worksheet #20 in the UFP-QAPP provides a summary of the required QC samples, frequency, and analyses necessary to complete the sampling activities. Section 4.7.2.1.6 of this FSP describes the QC sample nomenclature.

### **8.3 SEDIMENT SAMPLES**

The comprehensive analytical list for surface sediments is presented in Worksheet #15 of the UFP-QAPP. As identified in Worksheets #19 and #30 of the UFP-QAPP, the different analytical methods used for the sampling program have unique extraction and hold time requirements. The following protocol for sediment sample archival (via freezing) is proposed. The laboratory hold time for the COCs listed in Worksheet #15 of the UFP-QAPP is 2 years for metals, 180 days for mercury, and 1 year for other material held at  $-10^{\circ}\text{C}$ , including PCB Aroclors, PCDD/PCDFs, and DDx (EPA, 2017a; EPA, 2019b).

### **8.4 GEOTECHNICAL SAMPLES**

Geotechnical samples will be evaluated to assess the physical and engineering properties of the soils encountered during the site investigation. Geotechnical laboratory testing will be performed in accordance with current ASTM standards (Worksheet #12.10 of the UFP-QAPP).

## **9.0 DATA MANAGEMENT PLAN**

To ensure that environmental data collected at the SIB adheres to certain standards and practices, a programmatic level DMP (EPA, 2020b) was developed that provides overall guidance and data requirements for the various performing parties who conduct sampling under the PDI.

### **9.1 OVERVIEW**

The objective of this DMP is to ensure that environmental and engineering data and supportive information are collected and documented in a consistent manner and managed in a manner that preserves, protects, and makes the information available to stakeholders, primary parties (PPs), and other affected groups. This DMP applies to data and information collected in support of the PHSS by the PPs involved in RD sampling activities and select engineering activities. While previous sections cover how other information (e.g., photographs, field logs) is managed, this section is intended to address the type of data deemed critical to overall decision making and RD for the site.

### **9.2 FIELD DATA MANAGEMENT**

The following data management procedures will be performed for engineering and scientific activities in the field:

- Samples will be given a unique identifier (Section 4.7.2, Field Sample Identification, Tracking, and Labeling of this FSP).
- Samples will be collected and transported under CoC control (Section 4.7.3, Sample Chain of Custody of this FSP).
- Deviations from the FSP are clearly recorded in logbooks.
- Field logbooks and data sheets will be maintained (Section 6.1, Field Logbook of this FSP).
- Field QA/QC samples will be collected according to Worksheet #12 of the UFP-QAPP.

### **9.3 FIELD SAMPLING ACTIVITIES**

At end of each field day, the FTL will upload copies of the field records including physical and/or electronic field notes, field sampling forms, and CoCs to the HGL SharePoint site. Original logbooks and forms will be kept in the project file until project closeout.

#### **9.3.1 Electronic Data Management**

Field logbooks and field forms will be scanned into legible PDF and retained in both electronic versions on SharePoint and printed versions stored in a safe location for inclusion into site reports as appendices.

Field sampling data and analytical results will be maintained by HGL in EQUIS™ database developed by Earthsoft, Inc. Field measurements, sample data, and CoC information will be

managed electronically using an approved software tool. This software tool will be used to capture sampling, observational, and monitoring field data; print labels for collected samples; generate CoC documentation; and transmit CoC reports and sample collection information to the EPA PM or laboratory electronically. The field data will be uploaded to EQUiS™ daily in preparation for submittal of the analytical results and to facilitate electronic sample tracking. At the completion of field activities, the laboratory will prepare EQUiS™ EDDs with laboratory analytical data that the data manager will upload into the HGL EQUiS™ database. Unvalidated data will be flagged in the database as “draft.”

Contracted laboratories will follow EDD procedures covered in the UFP-QAPP and their respective subcontracts.

### **9.3.2 Post-Analysis Data Management**

Analytical laboratories will be required to adhere to QA/QC procedures outlined in the UFP-QAPP. Laboratories will provide data for field investigations in electronic format and QA/QC reports, including a narrative of the standard QA/QC protocols. Data validation and data management will be performed according to the UFP-QAPP by a third-party data validator.

The validator will be provided with an EQUiS™ validation EDD for each analytical package. The validator will update the EDD with validation qualifiers and reason codes; and will flag one result of any duplicate, dilution, or replicate analyses as “reportable.” Following data validation, the data validation EDD will be uploaded into the EQUiS™ database and the corresponding analytical results will be flagged as “final.” After data validation and database management are completed, final data summary files will be completed. The project database will allow for data export into formats consistent with other post-ROD sediment investigations.

## **9.4 ENGINEERING ACTIVITIES**

### **9.4.1 Electronic Data Management**

The Database Manager will incorporate select electronic field data into the engineer’s project database. Electronic data will be managed in accordance with the EPA *Program Data Management Plan: Portland Harbor Remedial Design Investigation* (EPA, 2020b) or the most up-to-date EPA guidance.

### **9.4.2 Post-Analysis Data Management**

Analytical laboratories will be required to adhere to QA/QC procedures outlined in the UFP-QAPP. Laboratories will provide data for field investigations in electronic format and QA/QC reports, including a narrative of the standard QA/QC protocols. Data validation and data management will be performed according to the UFP-QAPP by a third-party data validator.

Following data validation, data, supplementary information, and validator qualifiers will be compiled into a database for the project. After data validation and database management are completed, final data summary files will be completed. The project database will allow for data export into formats consistent with other post-ROD sediment investigations.

## **9.5 LABORATORY SELECTION**

With the large numbers of samples and multiple analytes, it is best to separate the sample analyses among laboratories that specialize in certain analytical methods and have the capacity to complete the work on schedule. For analytical consistency such as with preparation methods and detection and reporting limits, the same laboratories will be used to perform the physical and chemical analyses:

- A laboratory will be selected to analyze for chlorinated pesticides, PAHs, phthalates, TBT, and total solids.
- A laboratory will be selected to analyze for PCB Aroclors, total petroleum hydrocarbons diesel extended range, metals including mercury, total organic carbon, grain size, and total solids.
- A laboratory will be selected to analyze for dioxins/furans.
- A laboratory will be selected to analyze for PCB congeners and specific gravity.
- Laboratories with detection limits below ROD Table 17 CULs and/or ROD Table 21 RALs will be selected to the greatest extent practicable.

Samples will be placed in laboratory-supplied sample containers and preserved according to analytical protocols. Sample containers, preservation requirements, holding times, and sample sizes are provided for analytes and analyses in Worksheets #19 and #30 of the UFP-QAPP. Additional details on the analytical methods, QA/QC requirements and procedures, and laboratory-specific QA/QC requirements are detailed in the UFP-QAPP.

*This page was intentionally left blank.*

## **10.0 PERMITS AND ACCESS AGREEMENTS**

CERCLA response actions are exempt from the requirement to obtain federal, state, or local permits, and that exemption should apply to PDI sampling activities conducted under the terms of the ASAOC. Under the terms of the exemption, the work would still require coordination with regulatory agencies, and the work would have to meet the substantive requirements of the regulations applicable to those permits. Two specific permits that would normally apply to the PDI in-water sampling activities are identified and described below.

The investigation area is within the Willamette River, and the proposed sampling locations are below the OHW line in this area. These activities require Oregon Division of State Lands permission for access (i.e., application and fee for Short Term Access Agreement). Additionally, access agreements will need to be negotiated with the City to enter the stormwater conveyance systems and with private property owners to access the stormwater systems and riverbanks.

For sampling, if the total volume of sediment disturbed is less than 10 cubic yards, then the project would likely qualify for a Minimal Disturbance General Authorization. Per USACE, sediment sampling and other in-water disturbance activities are authorized under Nationwide Permit 6 – Survey Activities; submittal of a General Authorization application will be required. If EPA requires work outside of the in-water work window, USACE can authorize under a SLOPES STU variance. Applications should be submitted at least 6 months in advance of the in-water sampling.

*This page was intentionally left blank.*

## **11.0 HEALTH AND SAFETY**

Field survey and sampling activities will be conducted according to HGL’s Health, Safety, and Environment Program requirements, which include project-specific field safety instructions. In accordance with HGL policy, HGL field team members and subcontractors must successfully satisfy HGL and site-specific health and safety requirements before working on the site, including Drug-Free Workplace training, wearing required personal protective equipment, and other requirements of the field safety instructions. Employees working over or near water will be provided with U.S. Coast Guard-approved life jackets or buoyant work vests. See the project-specific HASP, which includes an ERP, for further information.

*This page was intentionally left blank.*

## **12.0 REPORTING**

Field sampling activities and results will be summarized in the PDI Evaluation Report. In accordance with the contract statement of work, the report will include the following:

- 1) Summary of the investigations performed;
- 2) Summary of deviations from the FSP;
- 3) Summary of investigation results;
- 4) Summary of validated data (i.e., tables and graphics);
- 5) Data validation reports and laboratory data reports;
- 6) Narrative interpretation of data and results;
- 7) Results of statistical and modeling analyses, if applicable;
- 8) Photographs documenting the work conducted; and
- 9) Conclusions and recommendations on whether the data is sufficient to complete the BODR.

Engineering data, particularly survey data, will be summarized in the PDI Evaluation Report and incorporated into the BODR.

## **TABLES**

*This page was intentionally left blank.*

**Table 2-1  
Data Gap Summary Table, Portland Harbor Superfund Site  
Field Sampling Plan, Swan Island Basin Project Area, Portland, Oregon**

<b>Data Type</b>	<b>Data Gaps</b>	<b>Proposed Data Collection</b>
Surface Sediment Contaminant Concentrations	Minor gaps in spatial coverage to characterize horizontal extent of contamination within SMA	30 surface samples to fill data gaps and refine delineation of SMA boundary (5 surface grabs, 25 samples collected from 0- to 1-foot interval of selected cores)
	Data needed to support analysis of short-term water quality effects during dredging activities	3 bulk sediment samples to support DRET
Subsurface Sediment Contaminant Concentrations	Insufficient core data to characterize vertical extent of contamination within SMA	171 cores to 10-foot depth (including 2 cores archived); 10 cores to 20-foot depth. Sample 150-foot grid
		Sample at 1-foot intervals from 1- to 6-foot depth for 10-foot cores, and 1- to 15-foot depth for 20-foot cores (total 985 samples)
Riverbank Characterization	Riverbanks within SIB Project Area not adequately characterized to assess source	Visual survey of physical bank conditions to evaluate erosion potential and delineate areas of potentially erodible sediments
	control sufficiency and inform stabilization as part of RD	Coordinate with geotechnical sampling program to evaluate geotechnical failure potential and characterize soil conditions (e.g., grain size, soil erodibility)
Geotechnical Site Characterization	Site stratigraphy and geotechnical design parameters	Historical geological and geotechnical records and survey maps
		New program of in-water borings, upland borings, CPTs, and groundwater elevation observations.
		Total of 31 borings and 15 CPTs
Sediment Porewater Characterization	No available data to map upward porewater migration within areas of potential sediment capping	Transect survey using vessel-mounted or towed instrument for thermal profiling at sediment/water interface within SMA
Stormwater Outfall and Conveyance System Sampling	Lack of adequate data on RPC loading from municipal and private outfalls to determine source	Inventory of the current status of discharges from private outfalls RPC exceedances in sediments
	control sufficiency and complete the Sufficiency Assessment Report	Conduct high-volume, flow-weighted sampling to support RPC load calculations at five municipal SW outfalls

**Table 2-1 (continued)**  
**Data Gap Summary Table, Portland Harbor Superfund Site**  
**Field Sampling Plan, Swan Island Basin Project Area, Portland, Oregon**

<b>Data Type</b>	<b>Data Gaps</b>	<b>Proposed Data Collection</b>
Stormwater Outfall and Conveyance System Sampling  (continued)		Collect SW grab samples and SW solids samples using in-line traps at 11 locations
		Conduct reconnaissance of six private outfalls to determine if additional sampling is necessary
Bathymetry and Topography	Complete recent multi-beam survey of the SIB Project Area for use in analysis and RD	Sitewide multi-beam bathymetric survey with complete coverage
Shoreline and Overwater Structures and Activities	Structural information required to make a functional structures determination and evaluate RA impacts on existing structures, and overwater activities to determine recontamination	Structural information for all potentially affected shoreline and over-water structures
		Mobile Terrestrial LiDAR Survey
		Land-based and water-based inspections
		Owner/operator interviews to evaluate activities and future use
Hydrodynamics and Sediment Dynamics Measurements	Hydrodynamic/transport processes for conceptual site model refinement, data for model validation, and data for direct use in RD	Owner/operator interviews to determine current and future navigation requirements
		Measurement of:
		Currents from vessel-mounted instruments
		Currents from bottom-mounted instruments
		Suspended sediments, wind waves, and boat wakes
Existing Utilities and Debris Identification	Locations and elevations of existing utilities and marine debris affecting RA	Sediment erodibility (SedFlume cores) at 30 locations
		Sub-bottom profile survey along transects
		Magnetometer survey along transects
Flood Impact Evaluation	Understanding of potential RA impacts on 500-year flood elevations	Side-scan sonar with complete coverage
		Flood impact modeling to evaluate potential net rise due to RA

**Table 2-1 (continued)**  
**Data Gap Summary Table, Portland Harbor Superfund Site**  
**Field Sampling Plan, Swan Island Basin Project Area, Portland, Oregon**

Data Type	Data Gaps	Proposed Data Collection
Habitat Conditions Survey	Aquatic and terrestrial habitat conditions in shallow nearshore zone and on riverbanks not adequately documented to support analysis of RD	Conduct a habitat conditions survey focused on shorelines to document bank conditions and substrate conditions within the shallow nearshore zone
	impacts to aquatic resources within waters of the U.S.	Coordinate habitat survey with riverbank characterization for efficiency based on overlapping information needs

**Notes:**

Study Area = Swan Island Basin Study Area between river miles 8.1 and 9.2

**Acronyms:**

- CPTs = cone penetration tests
- DRET = dredge elutriate testing
- LiDAR = light detection and ranging
- RA = Remedial Action
- RD = Remedial Design
- RPC = recontamination potential chemical
- SIB = Swan Island Basin
- SMA = Sediment Management Area
- SW = stormwater

**Footnotes:**

<sup>1</sup> Portland Harbor Superfund Site (PHSS) Record of Decision (ROD) Table 17 as revised by U.S. Environmental Protection Agency Errata #2 for PHSS ROD Table 17 dated January 14, 2020.

**Acronyms:**

µg/kg = micrograms per kilogram

mg/kg = milligrams per kilogram

B = Background-based number

BaP eq = benzo(a)pyrene equivalent

BEHP = bis(2-ethylhexyl)phthalate

DDD = dichlorodiphenyldichloroethane

DDE = dichlorodiphenyldichloroethene

DDT = dichlorodiphenyltrichloroethane

DDx = DDD + DDE + DDT

HxCDF = 1,2,3,4,7,8-hexachlorodibenzofuran

PAH = polycyclic aromatic hydrocarbon

PCB = polychlorinated biphenyl

PeCDD = 1,2,3,7,8-pentachlorodibenzo-p-dioxin

PeCDF = 2,3,4,7,8-pentachlorodibenzofuran

TCDD = 2,3,7,8-tetrachlorodibenzo-p-dioxin

TCDF = 2,3,7,8-tetrachlorodibenzofurans

TPH = total petroleum hydrocarbons

**Table 4-1  
Summary of Sample Activities, Numbers, and Analyses, Portland Harbor Superfund Site  
Field Sampling Plan, Swan Island Basin Study Area, Portland, Oregon**

Sample Type	Number of Stations	Number of Samples	Analyses
Surface Sediment	30	Surface samples: 30	All sediment COCs (ROD Table 17)
		5 grab only	
Subsurface Sediment Cores	181	Cores: 181	All sediment COCs (ROD Table 17)
		Samples: 985	
Sediment Erodibility (SedFlume)	30	30	Per subcontractor statement of work
Dredge Elutriate Sediments	3	3	All surface water COCs (ROD Table 17)
Riverbank	150	Surface Soils: 150	All riverbank soil COCs (ROD Table 17)
		Subsurface Soils: 150	
Geotechnical Investigation	Borings: 31	Between 12 and 17 (50-60 ft total; every 2-3 ft in the upper 15 ft and at 5- ft intervals thereafter)	Natural moisture content (ASTM D2216) Sieve analysis (ASTM D6913) Hydrometer analysis (ASTM D7928) Sieve and hydrometer analysis (ASTM D6913; ASTM D7928) Atterberg limits (ASTM D4318-17e1) Specific gravity determinations (ASTM D5550-14) Direct shear test (ASTM D3080) Consolidated undrained triaxial tests with pore pressure measurements (ASTM D4767) Consolidation tests (ASTM D2435)
	Cone Penetration Tests: 15		
Stormwater and Stormwater Solids	City of Portland Stormwater Outfall Stations: 5, 3 Events	HVS Stormwater: 15	All surface water COCs (ROD Table 17)
		HVS Solids: 15	Focused COCs
		12 Sediment Trap Stations - In-Line Solids: 24	Focused COCs
	Private Manhole Stations: 6	Manual Grab Aqueous: 18	All surface water COCs (ROD Table 17)
		Manual Grab Solids: 6	Focused COCs
City of Portland Stormwater Outfall Stations: 5	Manual Grab Solids: 5	Focused COCs	

**Notes:**

Surface samples will target 0- to 30-centimeter depth  
 Study Area = Swan Island Basin Study Area between river miles 8.1 and 9.2.  
 See Table 2.2 for details on focused COCs and SIB RPCs.

**Acronyms:**

ASTM = ASTM International  
COCs = contaminants of concern  
HVS = high-volume sampling  
ROD = Record of Decision

RPC = recontamination potential chemical  
SIB = Swan Island Basin  
TBD = To Be Determined based on Phase 1 results

**Notes:**

USACE conversion from CRD to NAVD88 for river mile 7.5 to 11.7 at Broadway Bridge: CRD is 5.28 ft above NAVD88 at river mile 9.7.

Subsurface samples will be collected from one side of a divided core from 1 to 6 ft at 1-ft intervals.

The other half and remaining undivided cores will be archived for future use. See FSP for more details.

Study Area = Swan Island Basin Study Area between river miles 8.1 and 9.2.

**Footnotes:**

a) Sample IDs will include water body name, sample type, location ID, sample interval in cm, and date.

b) Mudline elevations based on the center of the portion of each grid cell overlapping SIB. Actual sample locations may vary.

c) Minimum recovery is defined as 70% of the sampling interval (EPA, 2021)

d) 150- by 150-ft grid cells are 'Inside' when they fall entirely within the ROD-defined SIB SMA, 'Edge' when they overlap the SMA boundary, and 'Outside' when they fall entirely outside the SMA boundary.

**Acronyms:**

cm = centimeters

ft = feet

CRD = Columbia River Datum

ID = identification

EPA = U.S. Environmental Protection Agency

FSP = Field Sampling Plan

NAVD88 = North American Vertical Datum of 1988

ROD = Record of Decision

SIB = Swan Island Basin

SMA = Sediment Management Area

USACE = U.S. Army Corps of Engineers

Active	Inactive	Abandoned	Unknown
Active - City of Portland Municipal Outfalls (M-1, M-2, M-3, S-1 and S-2)			
Inactive - Former Non-Contact Cooling Water Discharge Points (WR-436 through WR-439)			

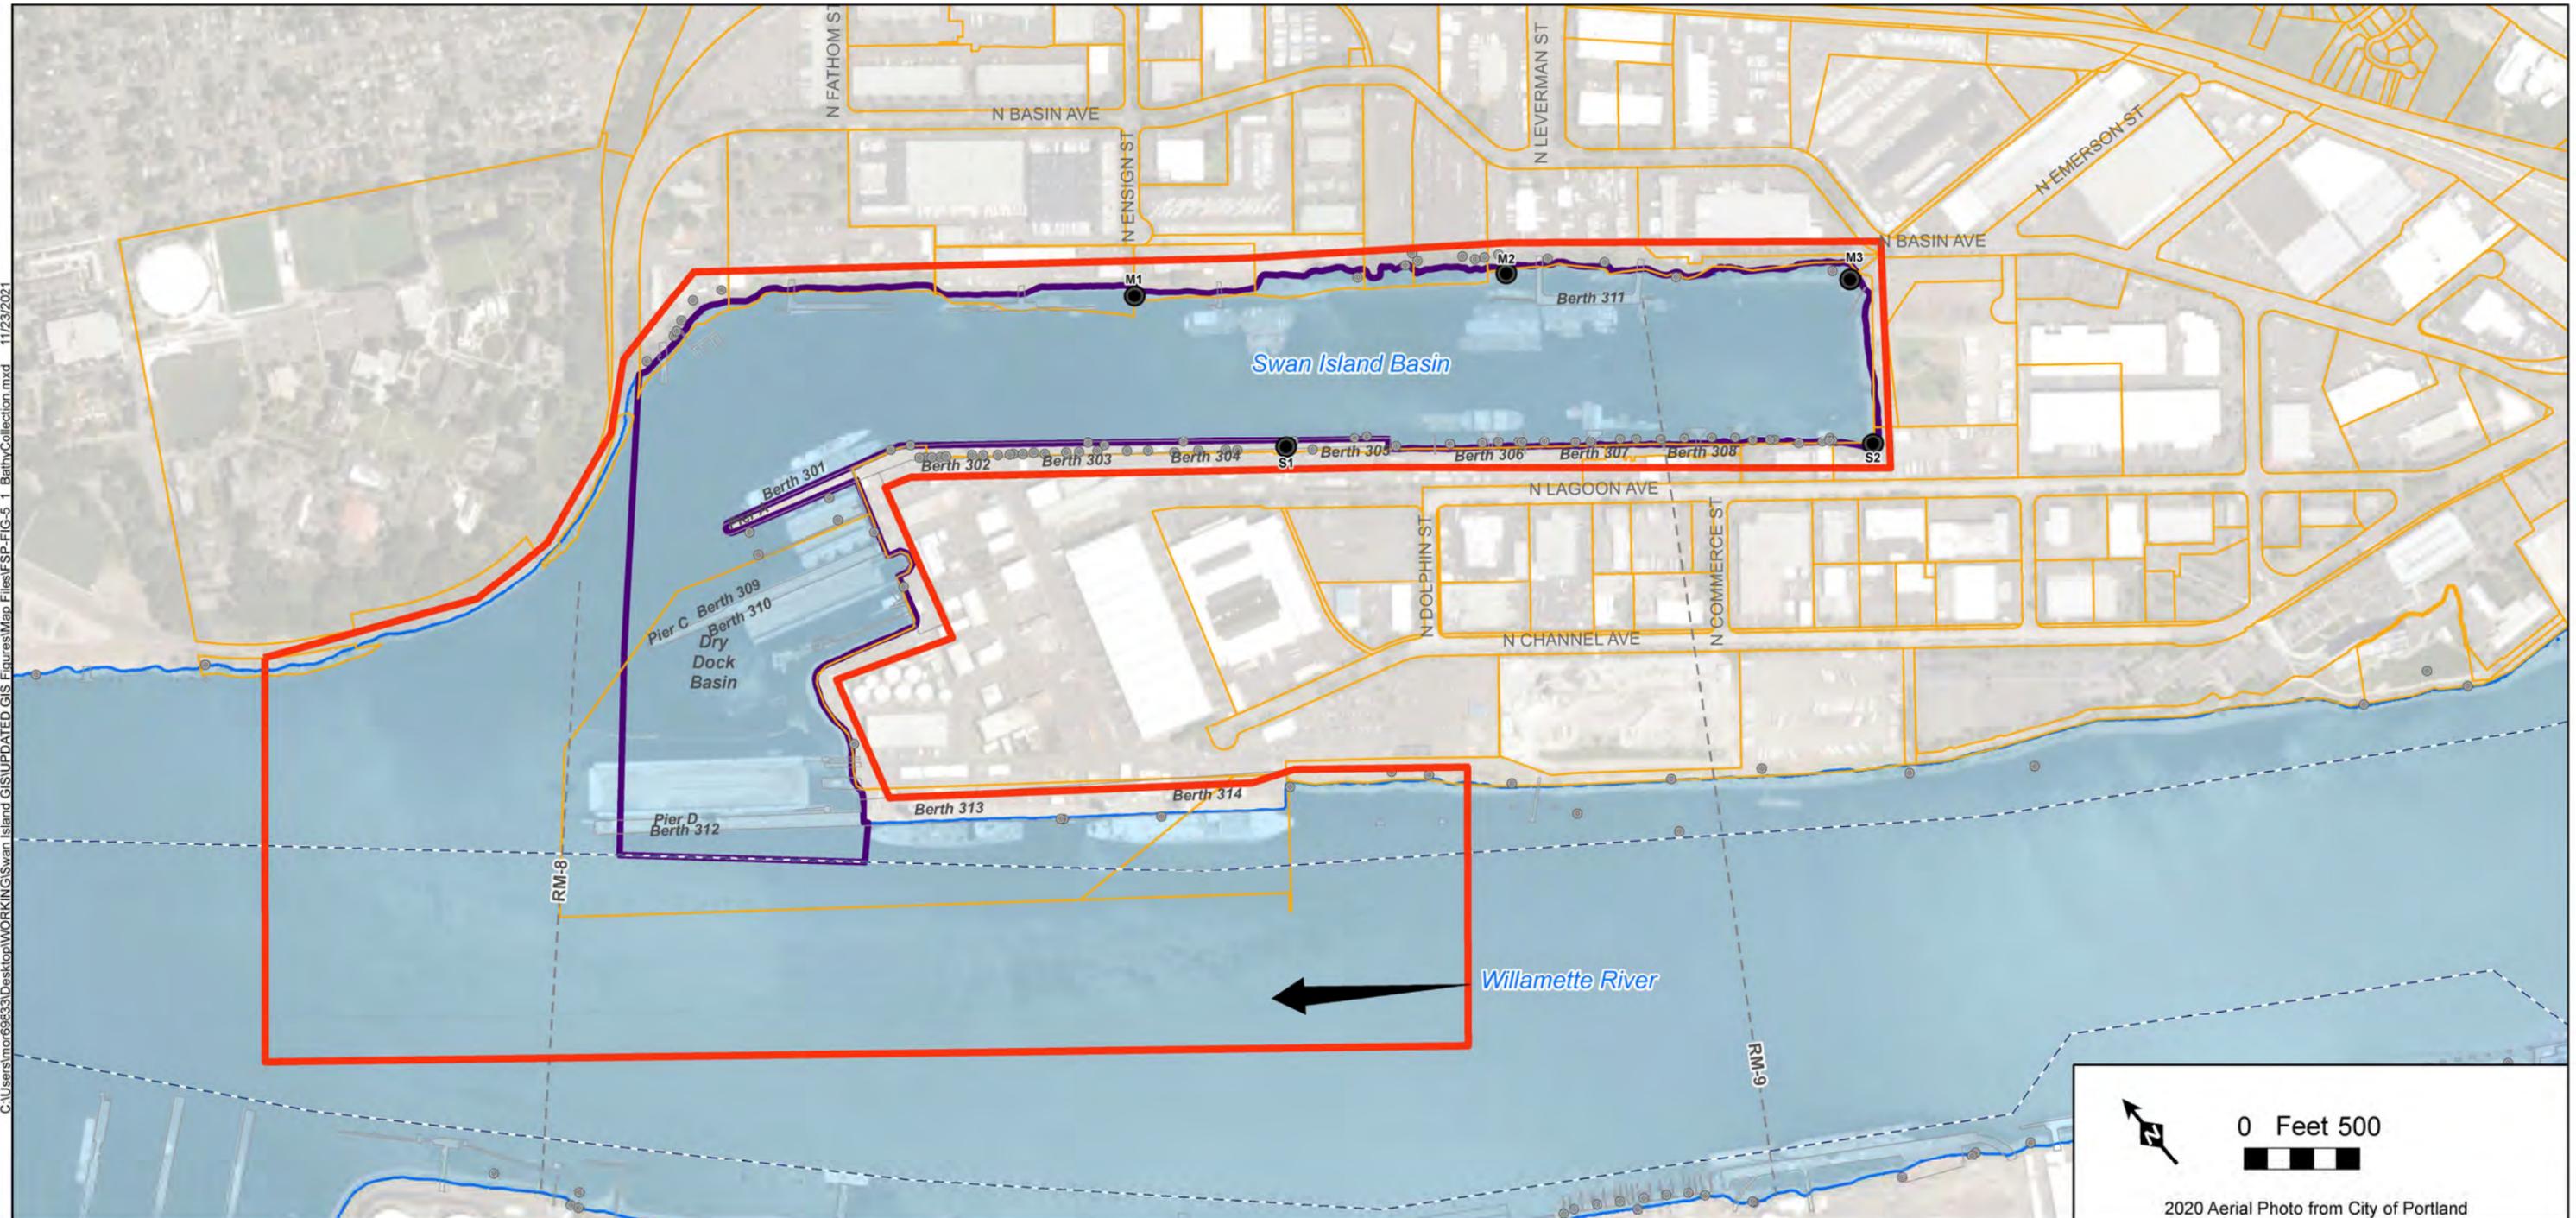

- Notes:
- EPA - U.S. Environmental Protection Agency
  - HVS - High Volume Sampling
  - NOAA - National Oceanic and Atmospheric Administration
  - RI/FS - Remedial Investigation/Feasibility Study
  - ROD - Record of Decision
  - USACE - U.S. Army Corps of Engineers
- (1) The high volume sampling system methodology includes pumping stormwater at a consistent rate over the duration of the storm and running high volumes of water through the HVS system to distinguish between the dissolved and solids fractions and obtain ROD Cleanup Levels for focused contaminants of concern.
  - (2) The in-line sediment trap design is similar to that utilized in the EPA-approved Round 3A Stormwater Field Sampling Plan, Portland Harbor RI/FS (LWG, 2007). If possible, one trap will be installed in each lateral.
  - (3) Manual stormwater solid grab samples will be collected at time of manhole entry if a minimum of 8-oz of solids are present in manhole/lateral. If less than 8-oz of solids are present, then the manual grab sample locations shall be abandoned and alternative upstream locations will be inspected and selected.
  - (4) Stormwater grab samples will be collected using ISCO auto-samplers.
  - (5) Where visual outfall inspections reveal the presence of solids, a single composite manual grab sample will be collected from all outfalls on the property.

	<b>STANDARD OPERATING PROCEDURE</b>	
	Approved by: <b>Dick, Jeff</b>	<small>Digitally signed by Dick, Jeff Date: 2019.11.24 13:42:00 -05'00'</small> <b>Corporate Quality Manager</b>
<b>Field Logbook Use and Maintenance</b>	<b>SOP No.: 300.04 (formerly 4.07)</b>	
	<b>SOP Category: QA/QC</b>	
	<b>Revision No.: 3</b>	
	<b>Revision Date: November 20, 2019</b>	
		<b>Review Date: November 2021</b>

## 1.0 PURPOSE

The purpose of this standard operating procedure (SOP) is to describe the methods for use and maintenance of field logbooks. This procedure outlines methods, lists examples for proper data entry into a field logbook, and provides the standardized HGL format. Field logbooks provide a means for recording observations and activities at a site and are intended to provide sufficient data and observations to reconstruct field events. Logbooks are a primary source of evidence referenced during legal proceedings. The overall requirement is to document field activities without having to rely on memory.

## 2.0 SCOPE AND APPLICATIONS

This procedure provides guidance for logbook use and maintenance during routine field operations on environmental projects. Site-specific deviations from the methods presented herein must be approved by the assigned HGL project manager and the HGL project quality assurance/quality control officer. Consult the project-specific planning documents for other documentation requirements that apply to the project.

## 3.0 GENERAL REQUIREMENTS

All project work must be performed in accordance with the project-specific planning documents. Refer to the project-specific health and safety plan for relevant health and safety requirements.

Any deviations from specified project requirements must be justified to and authorized by the project manager and/or the relevant program manager and documented in the planning documents after consultation and approval by the client (refer to change or variance documentation requirements in the planning documents). Deviations from requirements are documented sufficiently to re-create the modified process and/or product and associated approvals.

All field personnel present on site to conduct work related to environmental projects are responsible for documenting field activities in project field logbooks. If field personnel are working in teams, one team member should be assigned to document the work performed. Documentation in the logbooks must be legible, and the logbooks must be maintained over the course of the project in accordance with this SOP.

The HGL field team leader, or approved designee, prepares daily logs to provide clients records of significant events, observations, and measurements taken in the field. These daily logs rely on documentation from the logbooks and should match.

<b>Field Logbook Use and Maintenance</b>	<b>SOP No.: 300.04 (formerly 4.07)</b>
	<b>SOP Category: QA/QC</b>
	<b>Revision No.: 3</b>
	<b>Revision Date: November 20, 2019</b>
	<b>Review Date: November 2021</b>

The HGL field team leader should check logbook entries at the end of each field day to ensure that they are complete/adequate and communicate any deficiencies and corrective measures immediately. Logbook entries should be reviewed on a regular basis by the project manager or an approved designee to verify that they have been completed in accordance with this SOP. This could be done as part of the three-phase control inspections for each task or definable feature of work. Regular reviews of logbook ensure that adjustments to the information in the logbook, if needed, can be made early on in the performance of the task and establish expectations for documented information.

## **4.0 PROCEDURE**

### **4.1 INTRODUCTION**

Field logbooks provide a means for recording and documenting for the record observations and activities at a site. Field logbooks are intended to provide sufficient data and observation notes to enable participants to reconstruct events that occurred while performing field activities and to refresh the memory of field personnel when drafting reports or giving testimony during legal proceedings. As such, all entries must be as factual, detailed, and as descriptive as possible so that a particular situation can be reconstructed without reliance on the memory of field crews. Field logbooks are not intended to be used as the sole source of project or sampling information. A sufficient number of logbooks are assigned to a project to ensure that each field team has a logbook at all times.

### **4.2 FIELD LOGBOOK IDENTIFICATION**

Field logbooks are bound books with consecutively prenumbered pages. Logbooks are permanently assigned to field personnel for the duration of the project or sampling event. When not in use, the field logbooks are to be stored in site project files. If site activities stop for an extended period (2 weeks or more), field logbooks are to be stored in the project files in the appropriate HGL office. The field logbooks are scanned on a regular basis, grouped in files by field event and by logbook, and stored electronically in the proper project file located on SharePoint.

The cover of each logbook contains the following information:

- Organization to which the book is assigned (HGL),
- Site name (including operable unit designation),
- Project number,
- Book number, and
- Start and end dates of the information in the logbook.

### **4.3 LOGBOOK ENTRY PROCEDURES**

Every field team must have a logbook, and each field activity is recorded in the logbook by a designated field team member to provide daily records of significant events, observations, and

<b>Field Logbook Use and Maintenance</b>	<b>SOP No.: 300.04 (formerly 4.07)</b>
	<b>SOP Category: QA/QC</b>
	<b>Revision No.: 3</b>
	<b>Revision Date: November 20, 2019</b>
	<b>Review Date: November 2021</b>

measurements during field operations. Beginning on the first blank page and extending through as many pages as necessary, the following list provides examples of useful and pertinent information that may be recorded (optional).

- Serial numbers and model numbers for equipment that will be used for the project duration,
- Formulas, constants, and example calculations,
- Useful telephone numbers, and
- County, state, and site address.

Entries into the logbook may contain a variety of information. At a minimum, the following information must be recorded on the first page of the logbook entry for each workday:

- Date (on all pages),
- Site name, site location, and project number,
- Weather at start of day and projected for the day (changes during the day should be documented at the time of the change),
- Names of field personnel and subcontractors present and directly involved in the field activities, with their initials in order to reference them by initials during the day to facilitate note taking,
- Level of personal protective equipment being used on the site,
- Equipment used and calibration procedures followed,
- Start time, and
- Any field calculations.

In addition, information recorded in the field logbook during the day includes, but is not limited to, the following:

- Sample description including sample numbers, collection time, depth, volume, type and number of containers, preservative, and media sampled;
- Information on field quality control samples (e.g., duplicates, trip blanks, rinsates, and matrix spike/matrix spike duplicates [MS/MSDs]);
- Sample courier airbill numbers and associated chains of custody numbers;
- Observations about site and samples (odors, appearances, etc.);
- Information about any activities, extraneous to sampling activities, that may affect the integrity of the samples;
- Any public involvement, visitors, or press interest, comments, or questions; as well as times present at site;
- Equipment used on site including time and date of calibration along with calibration gas/fluid lot numbers and expiration dates, and calibration results;

<b>Field Logbook Use and Maintenance</b>	<b>SOP No.: 300.04 (formerly 4.07)</b>
	<b>SOP Category: QA/QC</b>
	<b>Revision No.: 3</b>
	<b>Revision Date: November 20, 2019</b>
	<b>Review Date: November 2021</b>

- Background levels of each instrument and possible background interferences;
- Instrument readings for the borehole, cuttings, or samples in the breathing zone and from the specified depth of the borehole, etc.;
- Field parameters (pH, specific conductivity, etc., as required by the sampling method and planning documents);
- Unusual observances, irregularities, or problems noted on site or with instrumentation used;
- Maps or photographs acquired or taken at the sampling site, including photograph numbers and descriptions;
- A photographic log that lists subject, person taking photograph, distance to subject, direction, time, photograph number, and noteworthy items for each photograph stating what feature/item the photo is documenting;
- A description of the investigation-derived waste (IDW) generated, the quantity generated, and the manner of IDW storage employed; and
- Forms numbers/titles and any information contained therein used during sampling (Note that a form does not take the place of the field logbook.).

All logbook entries are made in indelible black or blue ink. No erasures are permitted. If an incorrect entry is made, the data is crossed out with a single strike mark and initialed and dated by the originator. Entries are to be organized into easily understandable tables if possible. A sample format is shown in Attachment 1. A Logbook Quick Guide, which provides logbook entry requirements and suggestions, is included as Attachment 2. This guide can be copied and taped to the inside cover of a logbooks for quick reference.

All logbook pages are initialed and dated at the top of each page. The time (in 12- or 24-hour format) is recorded next to each entry. No pages or spaces are left blank. If the last entry for a day is not at the end of a page, a diagonal line is drawn through the remaining space, and the line is signed and dated.

Logbooks can become contaminated when used in the field. Every effort should be made by the field team to avoid contaminating the logbook. Logbooks can be kept in seal-top poly bags, or temporary plastic covers may be used.

#### **4.4 REVIEW**

The assigned field team leader, or an approved designee, checks field logbooks for completeness and accuracy on an appropriate site-specific schedule determined by the project leader. Any discrepancies in the logbooks are noted and returned to the originator for correction. The originator or other field team member knowledgeable about the field task reviews the comments, makes

0700 Arrive on site

Weather: 80°, sunny, slight breeze (~5 mph) from southwest.

VOS Field Team: EPA OSC:

M.R. Smith

K.W. Wagner

P.R. Lane

PRP representative, L.M. Stein, will be accompanying the VOS Field Team.

Personal Protective Equipment - LEVEL D

will be used on-site (refer to site-specific health & safety plan).

All equipment will be decontaminated as follows:

- Brush equipment scrub brush to remove gross particulates.
- Scrub thoroughly with Alconox/water solution.
- Rinse with reagent-grade distilled water.

- Rinse with reagent-grade Methanol.
- Rinse with reagent-grade distilled water.

Allow equipment to gravity drain. Wrap equipment in tinfoil if not immediately used.

Sample procedure:

All surface water samples will be taken using a clean decontaminated TEFLON scoop; stainless steel spoon and stainless steel bowl will be used for sediment samples.

AV 11/10/95

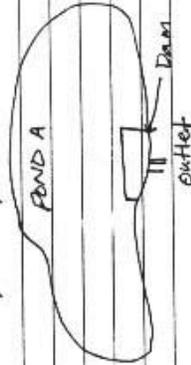

3

The samples will be taken from the ponds at the center of the dam opposite the outlets. (see below; refer to sample plan).

All total suspended solids (TSS) samples will be collected in a 500 ml polystyrene bottle - No preservative is necessary.

All VOA samples will be collected in two 40-ml amber glass vials and will be collected first. Preservation will be 4°C (ice).

→ Meters (pH) Decon = Rinse with reagent-grade distilled water

0730: Leave trailer. Go to sample location SS-1 @ Pond A.

0745: Arrive @ Pond A. Decon. equipment as described - on page 2 of this logbook.

**SOP 403.02, SIB Project Area, PHSS  
(Source: Hand-Operated Auger Soil Sampling)**

	<b>STANDARD OPERATING PROCEDURE</b>	
	Approved by: <b>Jeff Dick</b>	<small>Digitally signed by Jeff Dick DN: cn=Jeff Dick, o, ou, email=jdick@hgl.com, c=US Date: 2019.08.02 07:28:29 -04'00'</small> Corporate Quality Manager
<b>Hand-Operated Auger Soil Sampling</b>	<b>SOP No.: 403.02 (formerly 2.03)</b>	
	<b>SOP Category: Environmental Services</b>	
	<b>Revision No.: 2</b>	
	<b>Revision Date: August 1, 2019</b>	
	<b>Review Date: August 2021</b>	

## 1.0 PURPOSE

The purpose of this standard operating procedure (SOP) is to describe the standard method and equipment used to collect soil samples at the surface or in shallow subsurface using a hand auger.

## 2.0 SCOPE AND APPLICATION

This procedure yields a disturbed sample and applies to a wide variety of soil types including sands, clays, and silts. A hand auger is typically a small, lightweight metal cylinder (bucket), open at both ends with a cutting bit on the bottom. Diameters typically range between 1 and 4 inches. A T-shaped handle is attached to the top of the bucket by extendable rods. The augers are rotated into the ground until the bucket is full, then lifted out of the borehole and emptied. The maximum depth of hand auger investigations is typically 10 feet below ground surface. The use of an auger is of limited value in rocky soil. This procedure is not appropriate for collecting samples at a discrete depth, but may be used to collect samples at an approximate depth.

## 3.0 GENERAL REQUIREMENTS

All work must be performed in accordance with the project-specific planning documents. Refer to the project-specific health and safety plan for relevant health and safety requirements.

Any deviations from specified requirements must be justified to and authorized by the project manager and/or the relevant program manager. Deviations from requirements must be sufficiently documented to re-create the modified process.

## 4.0 EQUIPMENT

The equipment required may include hand-operated, spiral-type, ship-type, open-tubular, orchard-barrel, open-spiral, closed-spiral, post-hole, clamshell, Edelman, or Iwan augers. Augers typically are used with 3- to 4-foot-long metal extension rods and T-handles (fixed or ratcheted). The use of stainless steel augers is preferred. Augers plated with chrome or coated with other materials, except Teflon<sup>®</sup>, cannot be used.

Sampling tools and equipment should be protected from contamination sources before sampling and decontaminated before and between sampling locations, as specified in SOP 2.01: *Sampling Equipment Cleaning and Decontamination*.

<b>Hand-Operated Auger Soil Sampling</b>	<b>SOP No.: 403.02 (formerly 2.03)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: August 1, 2019</b>
	<b>Review Date: August 2021</b>

## 5.0 PROCEDURES

1. Don clean gloves. Using a decontaminated stainless steel spoon or other approved utensil, remove surface vegetation and debris from the immediate area around the marked sampling point.
2. Do not allow sampling equipment to touch potentially contaminated surfaces.
3. Record the appropriate information and observations about the sample location in the field logbook.
4. Assemble the decontaminated auger, extension, and T-handle, if necessary, and advance the auger into the soil to the desired depth. Mark the length of the hand auger rods every 0.5 foot to determine auger head depth relative to the ground surface when advancing or tag the bottom of the borehole (if the borehole stays open) with a weighted tape measure or water level meter.
5. Withdraw the auger from the soil.
6. If a sample is not being collected, remove the soil from the auger bucket and repeat Steps 4 and 5. While removing the soil from the auger bucket, the subsurface lithology should be described as specified in SOP 2.14: *Geologic Borehole Logging*. If a sample is to be collected in the next depth interval, replace the auger bucket with a clean decontaminated bucket and repeat Steps 2 through 4. Change gloves at each sampling location, or each time a new sample is to be collected, to avoid cross-contamination.
7. Perform any field monitoring required in the project-specific planning documents.

If collecting samples for analyses other than volatile organic compound (VOC) analyses, refer to Steps 8 and 9.

8. Using a decontaminated stainless steel spoon, spatula, disposable scoop, remove soil from the auger bucket and place in a stainless steel or glass container. Food-grade disposable aluminum pans may also be used but cannot be reused. Clean nitrile gloves may be donned to remove soil from the auger bucket by hand. Discard the top 2 or 3 inches of soil in the auger as this soil may consist of borehole slough from above. Mix or composite soil as directed by the project-specific planning documents. Using a decontaminated spoon or other approved utensil, remove any large rocks or other organic material (worms, grass, leaves, roots, etc.). Clean nitrile gloves may also be donned to remove large rocks or other organic material by hand.
9. Using a decontaminated stainless steel spoon, spatula, or disposable scoop, as appropriate, place soil samples in appropriate containers. Clean nitrile gloves may be donned to place soil into appropriate containers. Place samples in containers defined according to analytical

<b>Hand-Operated Auger Soil Sampling</b>	<b>SOP No.: 403.02 (formerly 2.03)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: August 1, 2019</b>
	<b>Review Date: August 2021</b>

needs specified in the project-specific planning documents, label samples, and then (when appropriate) pack on ice as soon as possible.

If collecting samples for VOC analysis, refer to Steps 10 and 11.

10. Remove the hand auger from the boring when the top of the specified sampling depth has been reached. Fit a slide-hammer to the top of the appropriate number of extension rods required to reach the total depth of the hole. Attach an impact sampler to the bottom of the extension rod(s) and drive the impact sampler into the soil to a depth of at least 6 inches. Remove the sampler from the borehole.
11. Collect VOC samples in accordance with SOP 403.01.0: *VOC Soil Sample Collection*. When samples are being collected for multiple analyses, samples that can be degraded by aeration (e.g., VOCs) are collected first and with the least disturbance possible to minimize analyte loss. VOC samples must not be composited.

## 6.0 REVISION HISTORY

Revision 0	December 2010	Initial Release
Revision 1	April 2017	Updated to incorporate lessons learned on the process and to reflect changes in SOP formatting.
Revision 2	August 1, 2019	Updated to incorporate lessons learned on the process and to reflect changes in SOP formatting.

**SOP 403.03, SIB Project Area, PHSS  
(Source: Soil or Sediment Sample Compositing)**

	<b>STANDARD OPERATING PROCEDURE</b>	
	Approved by: <b>Jeff Dick</b>	<small>Digitally signed by Jeff Dick DN: cn=Jeff Dick, o, ou, email=jdick@hgl.com, c=US Date: 2019.08.02 07:30:04 +0400</small>
<b>Soil or Sediment Sample Compositing</b>	<b>SOP No.: 403.03 (formerly 2.04)</b>	
	<b>SOP Category: Environmental Services</b>	
	<b>Revision No.: 4</b>	
	<b>Revision Date: August 1, 2019</b>	
	<b>Review Date: August 2021</b>	

## 1.0 PURPOSE

The purpose of this standard operating procedure (SOP) is to outline methods that may be used for field compositing soil or sediment samples before they are submitted to an analytical laboratory.

## 2.0 SCOPE

This procedure applies to compositing soil or sediment. This procedure does not apply to sample collection, but rather to combining samples in preparation for submittal for testing. Samples for volatile organic compound analyses must NOT be composited.

## 3.0 GENERAL REQUIREMENTS

All work must be performed in accordance with the site- or project-specific planning documents. Refer to the project-specific health and safety plan for relevant health and safety requirements.

Any deviations from specified requirements must be justified to and authorized by the project manager and/or the relevant program manager. Deviations from requirements must be sufficiently documented to re-create the modified process.

## 4.0 PROCEDURES

Soil or sediment that is to be sampled must be mixed as thoroughly as possible before being transferred to the sample container. Anomalous or suspected highly contaminated samples must be brought to the attention of the field manager.

- Soil or sediment that is composited must meet the following requirements:
  - Uniform collection techniques must be used to retrieve sample aliquots.
  - Aliquots must be of equal or known proportion.
  - The soil or sediment must be well mixed.
- The most common method of mixing (compositing) is referred to as quartering. The soil or sediment is placed in a pan or tray and divided into quarters. Each quarter is mixed individually, and then all quarters are mixed together to form a homogenous matrix. This procedure is repeated several times until the sample is adequately mixed. If round bowls are used for sample mixing, adequate mixing is achieved by stirring the soil or sediment in a circular fashion and occasionally turning the soil or sediment over. Mixing bowls and

<b>Soil or Sediment Sample Compositing</b>	<b>SOP No.: 403.03 (formerly 2.04)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 4</b>
	<b>Revision Date: August 1, 2019</b>
	<b>Review Date: August 2021</b>

stirring devices must be stainless steel and be decontaminated prior to use. Samples are homogenized before being placed into containers, except for volatile organic analyses.

- Sampling tools, instruments, and equipment must be protected from contamination sources before use and decontaminated after use as specified in SOP 2.01: *Sampling Equipment Cleaning and Decontamination*.
- Composite samples must be packaged, labeled, and prepared for shipment in accordance with the project-specific planning documents.
- The field logbook must be completed in accordance with procedures detailed in SOP 4.07: *Field Logbook Use and Maintenance*.

## 5.0 RECORDS

Documentation generated as a result of this procedure must be collected and maintained in accordance with requirements specified in the project-specific planning documents.

- Complete the field logbook in accordance with procedures listed in SOP 4.07: *Field Logbook Use and Maintenance*.

**(Source: Direct-Push Technology Soil and Groundwater Sampling)**

	<b>STANDARD OPERATING PROCEDURE</b>	
	Approved by: <b>Dick, Jeff</b>	Digitally signed by Dick, Jeff Date: 2020.06.18 16:04:57 -04'00'
<b>Direct-Push Technology Soil and Groundwater Sampling</b>	<b>SOP No.: 403.04 (formerly 2.05)</b>	
	<b>SOP Category: Environmental Services</b>	
	<b>Revision No.: 3</b>	
	<b>Revision Date: June 18, 2020</b>	
	<b>Review Date: June 2022</b>	

## 1.0 PURPOSE

The purpose of this standard operating procedure (SOP) is to describe the standard method and equipment used to collect soil and groundwater samples using direct-push technology (DPT).

## 2.0 SCOPE AND APPLICATION

The DPT soil sampling method applies to a wide variety of soil types including sands, clays, and silts. Samples may be collected from discrete intervals where high sample recovery rates can be achieved such as in clays and silts. However, where sample recovery rates are low, such as may be the case in loose sand, the sample collection depth intervals may be approximate. DPT soil sampling methods are of limited value in rocky soil. Where rocky soils limit the use of DPT, a different technology, such as hollow-stem auger drilling equipment, must be used. This procedure is appropriate for collecting groundwater samples at discrete depths.

## 3.0 GENERAL REQUIREMENTS

All work must be performed in accordance with the project-specific planning documents. Refer to the project-specific health and safety plan and project-specific quality assurance project plan for relevant health and safety and quality control requirements, respectively.

Any deviations from specified requirements must be justified to and authorized by the project manager and/or the relevant program manager. Deviations from requirements must be sufficiently documented to re-create the modified process.

## 4.0 PRECAUTIONS

The following precautions should be employed during DPT sampling operations:

- Subsurface and aboveground utility lines must be identified and cleared before exploratory boring drilling activities can be performed. Procedures outlined in HGL SOP 411.03: *Subsurface Utility Avoidance*, must be followed.
- Every attempt should be made to minimize the transfer of potentially contaminated material to downhole equipment, or to any equipment and supplies stored on the site.
- Every attempt should be made to contain contaminated soil and water and to prevent further contamination of the environment.

<b>Direct-Push Technology Soil and Groundwater Sampling</b>	SOP No.: 403.04 (formerly 2.05)
	SOP Category: Environmental Services
	Revision No.: 3
	Revision Date: June 18, 2020
	Review Date: June 2022

- Sampling tools and equipment must be protected from sources of contamination before sampling and decontaminated before and between sampling, as specified in SOP 411.02: *Sampling Equipment Cleaning and Decontamination*.

## 5.0 DPT SAMPLING PROCEDURES

DPT soil sampling is accomplished using a Geoprobe® or other similar truck- or track-mounted hydraulic sampler. DPT involves advancing a sampling probe using direct hydraulic pressure or a hydraulically driven rotary hammer. Boreholes are typically advanced using a 2.5- to 3-inch-diameter lead sampler attached to 1- or 2-inch-diameter probe rods, which are placed under hydraulic downward pressure. In unstable soils, a dual-tube system may be used where the lead sampler and center rods are used within larger diameter probe rods to prevent caving of material into the sample interval. Sampler sizes can vary from 1.25 to 4.5 inches in outer diameter (OD); however, 2.25- to 3.25-inch OD samplers are typical. Liner sizes can vary from 1.0 to 3.0 inches in internal diameter (ID); however, 1.125- to 1.85-inch ID liners are typical. Borings remain open only as long as necessary to collect the soil and/or groundwater samples and log the lithology, if required by the project-specific planning documents.

Specific sampling tools could require slightly different handling methods. For example, if sampling devices and probe rod extensions do not have quick-connect fittings, adjustable or pipe wrenches could be needed to change equipment configurations. The procedures described in this SOP are for power-driven DPT methods or tube samplers, and they are consistent with ASTM International Standard Guides D6282/D6282M-14 and D6001-05(2012).

### 5.1.1 Soil Sampling Procedures

The soil samples obtained using DPT are collected in acetate, brass, or stainless steel sampling tubes. Acetate tubes are most commonly used. Sampling is initiated at the soil interface, unless otherwise specified in the project-specific planning documents.

- Place plastic sheeting on the ground around the sampling location to prevent cross contamination.
- Attach the direct-push sampler with liner and cutting shoe to a rod extension.
- Clear the area to be sampled of any surface debris (e.g., twigs, rocks, litter). Remove the first 8 to 15 centimeters (cm) of surface soil from an approximately 15-cm radius around the drilling location to prevent near-surface soil particles from falling down the hole.
- Begin advancing the direct-push sampler, periodically removing accumulated soils. This step prevents accidentally brushing loose material back down the borehole when removing the sampler or adding probe rods.

## Direct-Push Technology Soil and Groundwater Sampling

SOP No.: 403.04 (formerly 2.05)

SOP Category: Environmental Services

Revision No.: 3

Revision Date: June 18, 2020

Review Date: June 2022

- After reaching the desired depth, slowly and carefully remove the direct-push tool from the boring. If collecting a core sample, remove the cutting shoe and liner from the sampler and replace it with a precleaned thin-walled tube sampler. Insert a disposable acetate liner into the sampler with optional core catcher, and install the sampler and cutting shoe.
- Carefully lower the sampler down the borehole and gradually force the sampler into the soil. Care should be taken to avoid scraping the borehole sides when not using a dual-tube system. Hammering the probe rods to facilitate coring should be avoided, as the vibrations could cause the borehole walls to collapse.
- Once the sampler reaches the top of the sampling interval, drive the sampler down into the soil the length of the corer.
- Pull the probe rods and sampler out of the hole.
- Remove the sampler by twisting to prevent losing the core and unscrew the probe rods.
- Remove the cutting shoe and remove the acetate liner containing the core from the device.
- Carefully cut the acetate liner to expose the core.
- Screen the core with a field detector as described in the project-specific planning documents. If required by the project plans, collect volatile organic compound (VOC) samples immediately after opening the acetate liner. VOC samples must be collected in accordance with SOP 403.01: *VOC Soil Sample Collection*.
- Discard the top of the core (approximately 2.5 cm), as it will contain any material collected by the corer before penetration of the layer being sampled.
- Provide a lithologic description in accordance with SOP 403.07: *Geologic Borehole Logging*.
- If homogenization of the soil sample is appropriate for the remaining analytical parameters, or if compositing of different locations is desired, follow the procedures detailed in SOP 403.03: *Soil or Sediment Sample Compositing*. Otherwise, transfer the sample into an appropriate container with a stainless steel spoon or equivalent and secure the cap tightly.
- Label the sample bottle(s) with the appropriate sample label as described in the project-specific planning documents. Complete the label carefully and clearly, addressing all the categories or parameters.
- Place filled sample containers on ice immediately.
- Complete all chain of custody documents and record information in the field logbook in accordance with procedures listed in SOP 300.04: *Field Logbook Use and Maintenance* and on the Field Sampling Report (Attachment 1).
- Prepare the samples for shipment in accordance with the project-specific planning documents.

<b>Direct-Push Technology Soil and Groundwater Sampling</b>	<b>SOP No.: 403.04 (formerly 2.05)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 3</b>
	<b>Revision Date: June 18, 2020</b>
	<b>Review Date: June 2022</b>

- Decontaminate sampling equipment after use and between sampling locations in accordance with procedures detailed in SOP 411.02: *Sampling Equipment Cleaning and Decontamination*.
- If no more cores are needed from the borehole, abandon the borehole with bentonite grout or chips and return the surface to its initial condition (e.g., topsoil, asphalt, or pavement).
- Soil generated during DPT activities that was not used for sampling should be treated as investigation-derived waste (IDW) and managed in accordance with the project-specific planning documents.

### 5.1.2 Groundwater Sampling Procedures

DPT groundwater samples can be collected using a hydropunch sampler. This type of groundwater sampling is best used for characterizing a site to determine the best placement of permanent wells. Procedures for collecting a water sample with a hydropunch are discussed in detail in this section. Note that the hydraulic conductivity of a formation could affect the time required to collect a sample. That is, more time could be required if groundwater recharge is slow. In those instances, the probe rods and hydropunch sampler can remain in the ground while the rig moves to another location to allow the water to recharge. After sufficient recharge, bailing or pumping can begin again.

- Place plastic sheeting on the ground around the sampling location to prevent cross contamination.
- Attach the sealed-screen sampler (hydropunch) to the probe rods.
- Clear the area to be sampled of any surface debris (e.g., twigs, rocks, litter). Remove the first 8 to 15 cm of surface soil from an approximately 15-cm radius around the drilling location to prevent near-surface soil particles from falling down the hole.
- Begin advancing the hydropunch. The screen is driven to a depth such that the middle of the screen is set at the sample target depth.
- After reaching the desired depth, retract the protective outer rod of the sampler to expose the screen to groundwater. If necessary, an instrument can be lowered down through the center of the probe rods to check the water level and ensure that the sampler has sufficient water for sampling.
- Lower tubing with check valve, bailer, or peristaltic pump down through the probe rods to the screen of the hydropunch to collect the groundwater sample. Groundwater samples are collected most commonly using polyethylene or Teflon<sup>®</sup> tubing with a check valve attached to the bottom. An up/down oscillating motion on the tubing pumps the water column up in the tubing to the ground surface or until enough water volume is in the tubing for the samples. Groundwater samples are collected directly from the bottom of the tubing, after removing the check valve, and placed in sample containers according to the project-specific planning documents.

<b>Direct-Push Technology Soil and Groundwater Sampling</b>	<b>SOP No.: 403.04 (formerly 2.05)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 3</b>
	<b>Revision Date: June 18, 2020</b>
	<b>Review Date: June 2022</b>

- Unless otherwise specified in the project-specific planning documents, collect the groundwater samples without purging sediment or groundwater to minimize disturbance to the sample.
- If sediment is expected in the sample, consider using sample containers without a hydrochloric acid preservative. Mixing the sediment often found in direct push groundwater samples with the hydrochloric acid causes a reaction that generates a gaseous product that creates unwanted headspace in the groundwater sample.
- If a bailer is used, retrieve the sample from the bailer and place it in an appropriate sample container.
- If a peristaltic pump is used, fill the appropriate sample container from the pump effluent tubing.
- If required, place a portion of the sample in a container to collect field parameters (temperature, pH, conductivity, dissolved oxygen, oxygen reduction potential, and turbidity).
- Label the sample bottles with the appropriate sample labels as described in the project-specific planning documents. Complete the label carefully and clearly, addressing all the categories or parameters.
- Place filled sample containers on ice immediately.
- Complete all chain of custody documents and record information in the field logbook in accordance with procedures listed in SOP 300.04: *Field Logbook Use and Maintenance* and on the Field Sampling Report (Attachment 1).
- Prepare samples for shipment in accordance with the project-specific planning documents.
- Pull the rods and hydropunch sampler from the hole.
- Decontaminate sampling equipment after each use and between sampling locations in accordance with procedures detailed in SOP 411.02: *Sampling Equipment Cleaning and Decontamination*.
- If additional samples are not needed from the borehole, abandon the borehole with bentonite chips and return the surface to its initial condition (e.g., topsoil, asphalt, or pavement).
- Manage IDW generated during hydropunch sampling in accordance with the project-specific planning documents.

## **6.0 RECORDS**

Documentation generated as a result of this SOP must be collected and maintained in accordance with requirements specified in the project-specific planning documents.

<b>Direct-Push Technology Soil and Groundwater Sampling</b>	<b>SOP No.: 403.04 (formerly 2.05)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 3</b>
	<b>Revision Date: June 18, 2020</b>
	<b>Review Date: June 2022</b>

- Document all daily field activities in the field logbook in accordance with procedures listed in SOP 300.04: *Field Logbook Use and Maintenance*.
- Complete a Field Sampling Report (Attachment 1) for each soil and groundwater sample.

**SOP 403.06, SIB Project Area, PHSS**  
**(Source: Surface and Shallow Depth Soil Sampling)**

	<b>STANDARD OPERATING PROCEDURE</b>	
	Approved by: <b>Dick, Jeff</b>	Corporate Quality Manager
<b>Surface and Shallow Depth Soil Sampling</b>	<b>SOP No.: 403.06 (formerly 2.13)</b>	
	<b>SOP Category: Environmental Services</b>	
	<b>Revision No.: 3</b>	
	<b>Revision Date: June 24, 2020</b>	
	<b>Review Date: June 2022</b>	

## 1.0 PURPOSE

The purpose of this standard operating procedure (SOP) is to describe the equipment and operations used for sampling surface and shallow depth soils. This procedure outlines the methods for soil sampling with routine field operations on environmental projects.

## 2.0 SCOPE AND APPLICATIONS

The objective of surface and shallow depth soil sampling is to ascertain the nature and extent of soil contamination at a site. The data can be used to identify contaminant sources, evaluate potential threats to human health or the environment, evaluate potential exposure pathways, or calculate environmental risks. For the purposes of this SOP, soil is defined as all unconsolidated materials above bedrock; surface soils are those that occur 0 to 6 inches below ground surface; and shallow depth soils are soils located above the bedrock surface and from 6 inches to 2 feet below ground surface.

## 3.0 GENERAL REQUIREMENTS

All work is performed in accordance with the project-specific planning documents. Refer to the project-specific health and safety plan for relevant health and safety requirements.

Any deviations from specified requirements must be justified to and authorized by the project manager and/or the relevant program manager and discussed in the approved project plans. Deviations from requirements must be documented sufficiently to re-create the modified process.

## 4.0 PROCEDURES

### 4.1 SAMPLING EQUIPMENT

Typically, equipment required for surface and shallow depth soil should be specified in the project field sampling plan or work plan. Equipment includes the following:

- Stainless steel mixing bowl,
- Stainless steel trowels or spoons,
- Stainless steel hand auger,
- Stainless steel core sampler that uses stainless steel or Lexan® liners (optional),
- Stainless steel shovel, and
- Appropriate sample containers.

<b>Surface and Shallow Depth Soil Sampling</b>	SOP No.: 403.06 (formerly 2.13)
	SOP Category: Environmental Services
	Revision No.: 3
	Revision Date: June 24, 2020
	Review Date: June 2022

Disposable sampling equipment items, such as a sampling spoon, may be used instead of stainless steel equipment. An example of a hand auger is provided in Attachment 1.

## 4.2 DECONTAMINATION

Before initial use, and after each subsequent use, all nondedicated or nondisposable sampling equipment must be decontaminated using the procedures outlined in HGL SOP 411.02: *Sampling Equipment Cleaning and Decontamination*.

## 4.3 SAMPLING LOCATION/SITE SELECTION

Follow the sample design criteria outlined in the project plan for each sampling event. Relocate the sample sites when conditions dictate, such as when natural or artificial obstructions are present at the proposed sample location (such as boulders or asphalt). Document the actual sample locations on a topographic map or site sketch and photograph all sample locations. GPS coordinates for the new location may also need to be recorded.

## 4.4 GENERAL

All boreholes and pits are filled in with the material removed during sampling unless otherwise specified in the project-specific planning documents. Where a vegetative turf has been established, fill in with native soil or potting soil and replace the turf if practical in all holes or trenches when sampling is completed.

### 4.4.1 Homogenizing Samples

Homogenizing is the mixing of a sample to provide a uniform distribution of the contaminants. Proper homogenization ensures that the containerized samples are representative of the total soil sample collected. All samples to be composited or split should be homogenized after all aliquots have been combined. **Do not homogenize (mix or stir) samples for volatile compound analysis. Follow the procedures outlined in HGL SOP 403.01: VOC Soil Sample Collection for collection of such samples.**

### 4.4.2 Compositing Samples

Compositing is the process of physically combining and homogenizing several individual soil aliquots of the same volume or weight. Compositing samples provide an average concentration of contaminants over a certain number of sampling points. Refer to HGL SOP 403.03: *Soil or Sediment Sample Compositing*.

### 4.4.3 Splitting Samples

Splitting samples is performed when multiple portions of the same samples must be analyzed separately. After preparation, fill the sample containers for the same analyses one after another in

<b>Surface and Shallow Depth Soil Sampling</b>	<b>SOP No.: 403.06 (formerly 2.13)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 3</b>
	<b>Revision Date: June 24, 2020</b>
	<b>Review Date: June 2022</b>

a consistent manner (parent sample for semivolatile organic compounds [SVOCs] analysis, then split sample for SVOC analysis; parent sample for total metals analysis, then split sample for total metals analysis; and so forth).

#### 4.5 SURFACE SOIL SAMPLING

Perform the following steps for surface soil sampling:

- Before sampling, remove leaves, grass, and surface debris from the area using a decontaminated stainless steel trowel or disposable sampling spoon.
- Label the lid of the sample container with an indelible pen or affix the sample label to the side of the jar. Tape over the label to seal out dirt and water before filling the container with soil, if possible.
- Collect surface soil samples with a decontaminated stainless steel trowel, spoon, or hand auger and transfer them to a decontaminated stainless steel bowl for homogenizing. If VOC analyses are to be conducted, collect the VOC sample first following the procedures outlined in HGL SOP 403.01: *VOC Soil Sample Collection*, then transfer the appropriate aliquot of soil to the decontaminated stainless steel bowl for homogenizing.
- Collect samples in the order of volatilization sensitivity. The most common collection order is as follows:
  - VOC,
  - Purgeable organic carbon,
  - Purgeable organic halogens,
  - Total organic halogens,
  - Total organic carbon,
  - Extractable organics,
  - Total metals,
  - Phenols,
  - Cyanide, and
  - Radionuclides.
- Immediately transfer the sample into a container appropriate to the analysis being performed.
- Place the samples in a cooler with ice. The temperature in the cooler must be maintained at approximately 4°C (if appropriate for analyses) for transport to an analytical laboratory.
- Material removed to collect the samples is returned to the boreholes and pits. Excess soil sample media should be treated as investigation-derived waste (IDW) and managed in accordance with the project-specific planning documents.
- Decontaminate all sampling equipment following HGL SOP 411.02, *Sampling Equipment Cleaning and Decontamination*.

<b>Surface and Shallow Depth Soil Sampling</b>	SOP No.: 403.06 (formerly 2.13)
	SOP Category: Environmental Services
	Revision No.: 3
	Revision Date: June 24, 2020
	Review Date: June 2022

#### 4.6 SURFACE SOIL SAMPLING (COMPOSITE SAMPLES ONLY)

Perform the following steps for surface soil (composite) sampling:

- Before sampling, remove leaves, grass, and surface debris from the area using a decontaminated stainless steel trowel.
- Collect surface soil aliquots with a decontaminated stainless steel spoon, trowel, or hand auger and place them in a stainless steel bowl and homogenize. Homogenize the sample in accordance with HGL SOP 403.03: *Soil or Sediment Sample Compositing*. Follow the procedures outlined in HGL SOP 403.01: *VOC Soil Sample Collection*, for samples collected for VOC analysis.
- Label the sample container and place it in a cooler chilled to 4°C . Complete the chain of custody record and pack it in the sample cooler.
- Material removed to collect the samples is returned to the boreholes and pits. Excess soil sample media IDW should be managed in accordance with the project-specific planning documents.
- Decontaminate all nondedicated sampling equipment following HGL SOP 411.02: *Sampling Equipment Cleaning and Decontamination*.

#### 4.7 SHALLOW DEPTH SOIL SAMPLING

Perform the following steps to collect shallow depth soil samples:

- Use a decontaminated stainless steel shovel to remove the top layer of soil and leaves, grass, and surface debris.
- Excavate soil to the pre-determined sampling depth using a decontaminated hand auger. Periodically remove the cuttings from the auger.
- When the proper sample depth is reached, remove the hand auger and all cuttings from the hole.
- Lower the decontaminated core sampler or hand auger to the bottom of the hole. When using a core sampler, it must contain a decontaminated liner appropriate for the constituents to be analyzed.
- Mark the sample interval on the hammer stem or auger.
- Operate the slide hammer on the core sampler to drive the sampler head into the soil, or advance the auger until it is flush with the interval mark at ground level.
- Record weight of hammer, length of slide, blow counts, and geologic soil data for all samples collected with a core sampler in the field logbook as outlined in HGL SOP

<b>Surface and Shallow Depth Soil Sampling</b>	SOP No.: 403.06 (formerly 2.13)

	Revision Date: June 24, 2020
	Review Date: June 2022

300.04: *Field Logbook Use and Maintenance*. This information may also be entered on Attachment 2, Surface and Shallow Soil Sampling Log.

- When the core sampler liner or auger has been advanced to the total depth of the required sample, remove it from the bottom of the hole.
- Immediately remove the liner from the core sampler and transfer the sample into a container or stainless steel bowl appropriate to the analysis being performed and then composite and homogenize it in accordance with HGL SOP 403.03: *Soil or Sediment Sample Compositing*. For VOC analysis follow the sample procedures outlined in HGL SOP 403.01: *VOC Soil Sample Collection*.
- Label the sample container and place it in a cooler chilled to 4°C . Complete the chain of custody record and pack it in the sample cooler.
- Material removed to collect the samples is returned to the boreholes and pits. Excess soil sample media IDW should be managed in accordance with the project-specific planning documents.
- Decontaminate all sampling nondedicated equipment following HGL SOP 411.02: *Sampling Equipment Cleaning and Decontamination*.

#### 4.8 ABANDONMENT PROCEDURES

Abandon boreholes and fill them to grade with the material removed for sampling, if approved, or clean fill.

#### 5.0 DOCUMENTATION

Record applicable sampling information in the field logbook as outlined in HGL SOP 300.04: *Field Logbook Use and Maintenance*. This information can also be entered on Attachment 2, Surface and Shallow Soil Sampling Log.

The project manager or an approved designee checks all field sheets and field logbooks used to record information during sampling for completeness and accuracy as soon as possible after the sampling event. Any discrepancies are noted, and the documents are returned to the originator for correction. The reviewer acknowledges that these review comments have been incorporated by signing and dating the “checked by” and “date” blanks on the field sheets and at the applicable places in the logbook.

## Basic Soil Sampling Kit - 5/8" Threaded

Technical Data Sheet • page 1 of 1

### DESCRIPTION:

Hand auger kit includes a Standard type Regular, Mud and Sand Auger plus an AMS Core Sampler\* with slide hammer. Included accessories are three 4 foot (1.2m) extensions, cross handle, cleaning brush, 2 crescent wrenches and slip wrench all contained in an AMS Deluxe storage and transport case. Two sizes of kit are available, 3 1/4 inch (8.3 cm) augers with 2 inch (5.1 cm) Core Sampler and 2 1/4 inch (5.7 cm) augers with 1 1/2" Core Sampler. Quick connect is not available with this kit.

### APPLICATION:

Use of the augers for accessing the sampling point at depths of up to about 12 feet (3.6 m) with the supplied extensions and AMS slide hammer. The sample may be collected within a removable retaining cylinder (liner). Plastic end caps are included.

### FEATURES

AMS Soil augers are designed to rapidly remove soils of all types, using the specially designed bits on the Regular, Mud, and Sand models. The auger tips are tungsten carbide hard surfaced and heat treated before sharpening. The core sampler features a heat treated coring tip on the cylinder and a threaded end cap. All attachment couplings are 5/8 NC threaded.

### BENEFITS

For your convenience, all the items necessary for accessing a sampling point and then taking a sample are included. AMS soil buckets are the most efficient available in terms of effort required and speed. The AMS Core Sampler allows immediate core examination or a sample may be collected in a retaining cylinder for later use.

### USE:

Assemble the chosen soil auger with an extension and cross handle. Place at the desired angle on the soil surface and turn three revolutions, or until full. Lift carefully from the hole and empty from the bail by tapping the cross handle on the ground. Repeat until the sampling depth is reached. Assemble core sampler to an extension(s) and slide hammer. Place in the hole and mark the extension six inches (5.1 m) above the soil surface. Use the slide hammer to drive in the the sampler to the mark and carefully remove. Disassemble, remove the liner and place the cap on each end.

### HELPFUL HINTS:

Use plumbers wick on 5/8 inch male threads used with Slide Hammer to help threads stay tight. Keep all fittings and samplers clean, dry and free of dirt or Mud. You can clean tooling with soapy water. Always dry to prevent rusting. Use a wire brush on male threads. Use vegetable oil on tools to prevent fittings locking up and rusting. When using augers, use rubber O-rings on male 5/8 inch thread to help take apart.

### SPECIFICATIONS:

AMS Soil Auger Kits are manufactured by AMS from all USA made materials. See separate AMS Technical Data Sheets for details on the Regular, Mud, Sand & Soil Augers, Core Sampler, Extensions, Cross Handles, Slide

Hammer, and Liners. Crescent wrenches are made from chrome plated forged steel. The cleaning brush is made with nylon bristles, with a twisted wire handle. The AMS Deluxe Case is molded from glass reinforced plastic with a lid gasket and lockable hasps.

### Kit Composed of the Following Items:

Item	Size	Part #	Size	Part#
1- Regular Auger	3 1/4"	400.06	2 1/4"	400.08
1- Mud Auger	3 1/4"	400.18	2 1/4"	400.20
1- Sand Auger	3 1/4"	400.40	2 1/4"	400.42
1- Cross Handle		406.04		406.04
3- Thrd. Extensions	4'	408.03	4'	408.03
1- Core Sampler*	2" x 6"	404.10	1 1/2" x 6	404.38
*w/slip wrench, liner & caps				
1- Slide Hammer		400.99		400.99
1-AMS Nylon Brush	2"	430.07	1 1/2"	430.11
2- Crescent Wrenches				421.10
1- Slip Wrench		421.29		421.29
1-AMS Deluxe Case		430.01		430.01
* Patent Pending, USA & Foreign				

### ANCILLARY ITEMS:

AMS Extensions, Liners, End Caps, End Cap Inserts, Sieves, Soil Color Charts, and Sample Containers.

	<b>STANDARD OPERATING PROCEDURE</b>	
	Approved by: Theresa Rojas	Digitally signed by Theresa Rojas Date: 2021.10.04 10:43:31 -04'00' Corporate Quality Director
<b>Geologic Borehole Logging</b>	<b>SOP No.: 403.07 (formerly 2.14)</b>	
	<b>SOP Category: Environmental Services</b>	
	<b>Revision No.: 2</b>	
	<b>Revision Date: October 4, 2021</b>	
	<b>Review Date: November 2021</b>	

## 1.0 PURPOSE

This Standard Operating Procedure (SOP) defines the methodology for conducting lithologic logging of cores, cuttings, split-spoon samples, and subsurface samples collected during field operations at sites where environmental investigations are performed by HGL.

## 2.0 SCOPE AND APPLICATIONS

The installation of monitoring wells, piezometers, and boreholes is a standard practice at many sites requiring environmental investigations. Following the guidelines presented in this SOP will help ensure that pertinent data is collected so that all borehole logs made while installing these devices at a site can be standardized to create a consistent, uniform database from which interpretive conclusions can be made with minimal decision error. A borehole log provides lithologic descriptions to characterize the physical subsurface and the geologic and hydrologic processes operating at the site. A properly prepared borehole log serves as an essential tool for evaluating and correlating these processes.

This SOP provides guidance for routine field operations on environmental projects, and was derived from *A Compendium of Superfund Field Operations Methods*, U.S. Environmental Protection Agency (EPA) (EPA/540/P-87/001 [Office of Solid Waste and Emergency Response {OSWER Directive} 9355.0-14]); and other industry standards.

## 3.0 GENERAL REQUIREMENTS

All work will be performed in accordance with the project-specific planning documents. Refer to the project-specific health and safety plan for relevant health and safety requirements.

Any deviations from specified requirements will be justified to and authorized by the project manager and/or the relevant program manager and discussed in the approved project plans. Deviations from requirements will be sufficiently documented to re-create the modified process.

## 4.0 PROCEDURES

### 4.1 INTRODUCTION

Boreholes should be logged by a trained geologist, or other earth scientist under the supervision of a geologist. Large-scale inferences such as vertical and horizontal extent of strata, facies changes, attitude of bedding or layering, structural features (faults, folds, fractures, dikes, etc.), location of the water table, lithologic characterizations, and the extent of subsurface contamination are made from small-scale observations recorded on the borehole log. These observations include bedding, grain

<b>Geologic Borehole Logging</b>	<b>SOP No.: 403.07 (formerly 2.14)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: October 4, 2021</b>
	<b>Review Date: November 2021</b>

size, degree of sorting, shape of grains, color, hardness, organic vapor levels, and other observable physical characteristics including visible evidence of contamination.

Logging should document both general and specific lithologic information about the borehole. In all cases, the lithologic log should be identified with the following:

- Specific site number,
- Well/boring number,
- Drilling method,
- Location,
- Date of drilling,
- Individual logger (geologist),
- Drilling contractor,
- Significant organic vapor reading,
- Visible evidence of contamination, such as staining or odor,
- Depth to water first encountered,
- Final depth of water level,
- Well/boring elevation (if data is available),
- Total depth in feet,
- Graphic log, and,
- Lithologic description.

Lithologic descriptions for unconsolidated materials often use the Unified Soil Classification System (USCS) or standard geologic field description methods (Compton, 1962).

Lithologic descriptions of unconsolidated material should contain the following characteristics when possible:

- Soil or formation name,
- Gradation degree of sorting,
- Principal constituent,
- Specific descriptors for principal constituents (for example, plasticity, grain size, and shape),
- Firmness/hardness,
- Minor constituents,
- Moisture content,
- Color,
- Particle morphology, and

<b>Geologic Borehole Logging</b>	<b>SOP No.: 403.07 (formerly 2.14)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: October 4, 2021</b>
	<b>Review Date: November 2021</b>

- Other descriptors (such as, visual evidence of contamination, specific monitoring equipment readings including photoionization detector [PID]/organic vapor analyzer [OVA] readings).

## **4.2 CLASSIFICATION SYSTEM**

The following subsections describe in detail the parameters and descriptive terminology used to classify each sample for the borehole log.

### **4.2.1 Soil or Formation Name**

The soil or formation name will include the major constituent(s) and may be preceded by a single-word modifier indicating the subordinate constituent. Percentages of each constituent will be used to classify the material without actually recording constituent percentage. The textural terms used to classify a soil are shown in Attachment 1, Triangular Diagram Showing Percentage of Sand, Silt, and Clay in Each Textural Class. If logging unconsolidated materials, a USCS symbol should be recorded. The USCS symbols are provided in Attachment 2, Unified Soil Classification System Table.

### **4.2.2 Gradation (Degree of Sorting)**

Size sorting describes the extent to which grain size is uniform. The comparison chart listed in Attachment 3, Comparison Chart for Estimating Degree of Sorting, is used to describe coarse-grained soils being logged from a borehole. The USCS describes soils in terms of grading, which is the opposite of sorting. For example, a poorly graded sand (USCS classification SP) is well sorted and has a predominant grain size, and a well graded gravel (USCS classification GW) is poorly sorted and has a wide distribution of grain sizes.

### **4.2.3 Principal Constituent**

Principal constituents recorded during borehole logging include an identification of the following unconsolidated material types in order of increasing grain size:

- Clay,
- Silt,
- Sand,
- Gravel,
- Cobbles, and
- Boulders.

If known, an identification of the potential source of the material should be made (such as alluvium, colluvium, artificial fill, or residual material).

<b>Geologic Borehole Logging</b>	<b>SOP No.: 403.07 (formerly 2.14)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: October 4, 2021</b>
	<b>Review Date: November 2021</b>

#### 4.2.4 Principal Constituent Descriptors

Additional descriptors for the principal material constituents may be added to the log to further delineate or accurately record subtle changes in the lithologic structure. Modifiers such as grain size, shape, and plasticity of materials (high, medium, and low plasticity). (Note: Plasticity is the property of permanently changing shape without movement on any visible fractures.)

#### 4.2.5 Consistency/Density/Rock Hardness

The characteristics of unconsolidated material are often determined by hand or the Standard Penetration Test (SPT).

Hand testing of unconsolidated material involves pressing the thumb into the undisturbed material to determine its consistency based on the following descriptors:

<u>Depth of Thumb Imprint</u>	<u>Cohesive Consistency (Clay)</u>
Greater than 1 inch	Very soft
Approximately 1 inch	Soft
Approximately ¼ inch	Firm
Thumb will not indent soil but readily indented by fingernail	Hard
Thumb nail will not indent soil	Very hard

The SPT involves driving a split-spoon sampler into the material by dropping a 140-pound weight from a height of 30 inches. The resistance of the material is reported in the number of blows of the weight required to drive the spoon one foot and translates into the following descriptors:

<u>Number of Blows/Foot</u>	<u>Cohesive Consistency (Clay)</u>
0–2	Very soft
2–4	Soft
4–8	Medium
8–15	Stiff
15–30	Very stiff
30+	Hard

<u>Number of Blows/Foot</u>	<u>Cohesive Consistency (Gravel)</u>
0–4	Very loose
4–10	Loose
10–30	Medium dense
30–50	Dense
50+	Very Dense

<b>Geologic Borehole Logging</b>	<b>SOP No.: 403.07 (formerly 2.14)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: October 4, 2021</b>
	<b>Review Date: November 2021</b>

<u>Number of Blows/Foot</u>	<u>Rock Hardness</u>
<20	Weathered
20–30	Firm
30–50	Medium Hard
50–80	Hard
80+	Very Hard

#### 4.2.6 Minor Constituents

Constituents not previously described in the principal constituent description may be described as a percentage or by weight. Typically, modifiers for minor constituents conform to the following standards:

- No modifier < 5 percent,
- Slightly 5 to 12 percent,
- Moderately (add ‘-y’ or ‘-ey’ such as silty clay) 12 to 40 percent, or
- Very 40 to 50%.

#### 4.2.7 Moisture Content

The terms used to describe the relative moisture content of a field soil sample are as follows:

- Dry – The sample is completely without moisture. Dry, silty sands, for example, will produce suspended particles when dropped by hand.
- Damp – Samples containing a very slight amount of water.
- Moist – Soils in this range are near the maximum water content for their maximum compactibility or density. Moist fine-grained soils with a water content greater than their plastic limit will form a ball when compressed in the hand.
- Wet – The soil samples are wet enough to produce free water upon shaking but still contain unoccupied air voids. Fine-grained soils close to the liquid limit would be termed wet.
- Saturated – Soils with no air voids. Samples placed in sample jars or bags will probably have standing water after a short period of time.

#### 4.2.8 Plasticity

The plasticity of fine-grained soils is recorded on the borehole log. A fine-grained soil can be non-plastic or have low, medium, or high plasticity. The plasticity is measured by the ability to roll the material into a 1/8-inch-thick thread based on the following descriptors:

<b>Geologic Borehole Logging</b>	<b>SOP No.: 403.07 (formerly 2.14)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: October 4, 2021</b>
	<b>Review Date: November 2021</b>

- Non-plastic – The thread cannot be rolled at any water content.
- Low plasticity – The thread can barely be rolled and a lump cannot be formed when drier than the plastic limit.
- Medium plasticity - The thread is easy to roll and not much time is required to reach the plastic limit. The thread cannot be rerolled after reaching the plastic limit. The lump crumbles when drier than the plastic limit.
- High plasticity – It takes considerable time rolling and kneading to reach the plastic limit. The thread can be rerolled several times after reaching the plastic limit. The lump can be formed without crumbling when drier the plastic limit.

#### **4.2.9 Color**

The color of soil and associated materials will be recorded on the borehole log. Color descriptors should include but are not limited to the following descriptors: black, gray-black, brown, olive, mottled, and streaked. A Munsell Soil Color Chart should be used to provide general logging guidance, but specific use is not necessary for adequately describing lithology.

#### **4.2.10 Particle Morphology**

The key elements of particle morphology are roundness and sphericity. Roundness is a measure of the curvature of grain corners. Sphericity is a measure of how equal the three axial lengths (x, y, z) of an object are. Determination of both properties is facilitated by the use of a hand lens. Estimate grain roundness and sphericity in coarse-grained soils by using an American Geological Institute (AGI) data sheet (Attachment 4).

#### **4.2.11 Other Descriptors**

Field screening data collected during the drilling process may help further characterize site conditions during subsurface investigations. Readings from on-site monitoring equipment such as PIDs, flame ionization detectors (FIDs), or OVAs should be recorded at each sample interval. Other useful information includes the organic content and the presence or absence of waste material in samples.

#### **4.2.12 Particle Size Distribution**

An estimate of particle sorting by grain size is often useful for borehole logging purposes. Precise estimates of percent composition of the sample are not necessary.

<b>Geologic Borehole Logging</b>	<b>SOP No.: 403.07 (formerly 2.14)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: October 4, 2021</b>
	<b>Review Date: November 2021</b>

### USCS Grain Size Categories

Exact Size Limits	Approximate Inch Equivalents	Name of Loose Aggregate
>256 mm	>10 in.	Boulder gravel
64–256 mm	2.5–10 in.	Cobble gravel
32–64 mm	1.2–2.5 in.	Very coarse pebble gravel
16–32 mm	0.6–1.2 in.	Coarse pebble gravel
8–16 mm	0.3–0.6 in.	Medium pebble gravel
4–8 mm	0.15–0.3 in.	Fine pebble gravel
2–4 mm	0.08–0.15 in.	Granule (or very fine pebble) gravel
1–2 mm	0.04–0.08 in.	Very coarse sand
1/2–1 mm	0.02–0.04 in.	Coarse sand
1/4–1/2 mm	0.01–0.02 in.	Medium sand
1/8–1/4 mm	0.005–0.01 in.	Fine sand
1/16–1/8 mm	0.002–0.005 in.	Very fine sand
1/256–1/16 mm	0.00015–0.002 in.	Silt
<1/256 mm	<0.00015 in.	Clay (clay-size materials)

mm = millimeters

Source: Wentworth Scale; Compton 1962

The Comparison Chart for Estimating Percentage Composition (Attachment 5) can be used to estimate the percentage of various grain sizes present in a sample. However, visual estimates usually provide sufficient information for characterizing site lithology.

### 4.3 BOREHOLE LOGS

Record data collected during exploratory boring soil logging in the field logbook and on Attachment 6, Borehole Log. Use this log on all applicable field drilling and subsurface sampling operations.

Geologic correlation and aquifer properties prediction are dependent on good exploratory boring sample descriptions. Rotary drilling with fluids is generally unacceptable since the drilling fluids may potentially contaminate the aquifer under investigation and provide inaccurate water levels. High quality borehole data are generally acquired with a direct-push acetate-lined sampler, a split-spoon sampler, or a sonic core barrel. This method of sampling provides detailed logging because the samples collected are undisturbed. The lithofacies interpreted from air-rotary or auger cuttings logs may lack the accuracy necessary for detailed correlation. Where possible, techniques such as geophysical borehole logging will be used to supplement cuttings descriptions. Note on the log any geologic description determined from borehole cuttings. The cuttings are often mixed over the entire length of the boring.

In bedrock formations, cuttings may be acquired from a reverse circulation, air rotary, or dual-wall rotary boring. These cuttings do not provide information on the in situ properties of the materials, but do provide adequate sample description information.

<b>Geologic Borehole Logging</b>	<b>SOP No.: 403.07 (formerly 2.14)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: October 4, 2021</b>
	<b>Review Date: November 2021</b>

In summary, close sample spacing or continuous sampling in a boring provide the best material for descriptive geology. Use traditional geologic terminology and supplement with the USCS descriptive system when appropriate. Provide sufficient data on layering and other sedimentary structures and undisturbed textures. Sample numbers, depths, and analytes should be included in each description. The applicable field methods described by Compton (1962) and AGI (1982) are recommended. These methods are fully referenced in Section 5.0.

#### **4.4 REVIEW**

Personnel conducting borehole logging of soil will record field data on Attachment 6, Borehole Log, and will record a chronological summary in the project logbook. The applicable methods outlined in this procedure shall be used to record the data on this log. The personnel conducting these operations will sign and date the “logged by” and “date” blanks on Attachment 6, Borehole Log.

The Project Manager or designee shall check all field generated data and Attachment 6, Borehole Log, for completeness and accuracy. Any discrepancies will be noted, and the logs will be returned to the originator for correction. The reviewer will acknowledge that corrections have been incorporated by signing and dating the “reviewed by” and “date” blanks on Attachment 6, Borehole Log.

UNIFIED SOIL CLASSIFICATION AND SYMBOL CHART		
<b>COARSE-GRAINED SOILS</b> (more than 50% of material is larger than No. 200 sieve size.)		
Clean Gravels (Less than 5% fines)		
<b>GRAVELS</b> More than 50% of coarse fraction larger than No. 4 sieve size		GW Well-graded gravels, gravel-sand mixtures, little or no fines.
		GP Poorly-graded gravels, gravel-sand mixtures, little or no fines.
	Gravels with fines (More than 12% fines)	
		GM Silty gravels, gravel-sand-silt mixtures
		GC Clayey gravels, gravel-sand-clay mixtures
Clean Sands (Less than 5% fines)		
<b>SANDS</b> 50% or more of coarse fraction smaller than No. 4 sieve size		SW Well-graded sands, gravelly sands, little or no fines.
		SP Poorly graded sands, gravelly sands, little or no fines.
	Sands with fines (More than 12% fines)	
		SM Silty sands, sand-silt mixtures
		SC Clayey sands, sand-clay mixtures
<b>FINE-GRAINED SOILS</b> (50% or more of material is smaller than No. 200 sieve size.)		
<b>SILTS AND CLAYS</b> Liquid limit less than 50%		ML Inorganic silts and very fine sands, rock flour, silty of clayey fine sands or clayey silts with slight plasticity
		CL Inorganic clays of low to medium plasticity, gravelly clays, sandy clays, silty clays, lean clays
		OL Organic silts and organic silty clays of low plasticity
<b>SILTS AND CLAYS</b> Liquid limit 50% or greater		MH Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts
		CH Inorganic clays of high plasticity, fat clays
		OH Organic clays of medium to high plasticity, organic silts
<b>HIGHLY ORGANIC SOILS</b>		PT Peat and other highly organic soils

LABORATORY CLASSIFICATION CRITERIA		
GW	$C_u = \frac{D_{60}}{D_{10}}$ greater than 4;	$C_c = \frac{(D_{30})^2}{D_{10} \times D_{60}}$ between 1 and 3
GP	Not meeting all gradation requirements for GW	
GM	Atterberg limits below "A" line or P.I. less than 4	Above "A" line with P.I. between 4 and 7 are borderline cases requiring use of dual symbols
GC	Atterberg limits above "A" line with P.I. greater than 7	
SW	$C_u = \frac{D_{60}}{D_{10}}$ greater than 4;	$C_c = \frac{(D_{30})^2}{D_{10} \times D_{60}}$ between 1 and 3
SP	Not meeting all gradation requirements for GW	
SM	Atterberg limits below "A" line or P.I. less than 4	Limits plotting in shaded zone with P.I. between 4 and 7 are borderline cases requiring use of dual symbols.
SC	Atterberg limits above "A" line with P.I. greater than 7	

Determine percentages of sand and gravel from grain-size curve. Depending on percentage of fines (fraction smaller than No. 200 sieve size), coarse-grained soils are classified as follows:

Less than 5 percent ..... GW, GP, SW, SP  
 More than 12 percent ..... GM, GC, SM, SC  
 5 to 12 percent ..... Borderline cases requiring dual symbols

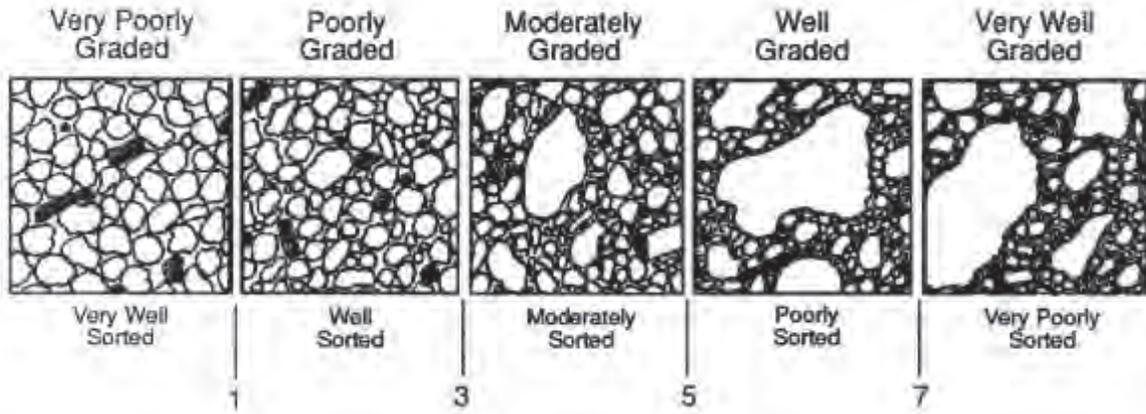

*This page was intentionally left blank.*

**COMPARISON CHART FOR ESTIMATING DEGREE OF SORTING**

*This page was intentionally left blank.*

**Attachment 3**  
**Comparison Chart for Estimating Degree of Sorting**

Terms for degrees of sorting. The numbers indicate the number of size-classes included by the bulk (80 percent) of the material. The drawings represent sandstones as seen with a hand lens. Silt and clay-size materials are shown diagrammatically by the fine stipple.

**SOP 403.08, SIB Project Area, PHSS  
(Source: Sediment Sampling)**

	<b>STANDARD OPERATING PROCEDURE</b>	
	Approved by: <b>Dick, Jeff</b>	<small>Digitally signed by Dick, Jeff Date: 2020.03.24 18:37:26 -04'00'</small> <b>Corporate Quality Manager</b>
<b>Sediment Sampling</b>	<b>SOP No.: 403.08 (formerly 2.15)</b>	
	<b>SOP Category: Environmental Services</b>	
	<b>Revision No.: 2</b>	
	<b>Revision Date: March 25, 2020</b>	
		<b>Review Date: March 2022</b>

## 1.0 PURPOSE

This standard operating procedure (SOP) establishes the guidelines for sediment sampling using a variety of sampling devices. Methods for preventing sample and equipment cross-contamination are included. Proper sediment sampling ensures that any evaluations of sediment contamination are based on actual contaminant levels and are not based on improper sampling techniques.

This SOP provides guidance for routine field operations on environmental projects. Site-specific deviations from the methods presented herein must be approved by the HGL project manager.

## 2.0 SCOPE AND APPLICATIONS

Field personnel collecting sediment samples are responsible for performing the applicable tasks outlined in this procedure when conducting work related to environmental projects.

The project manager or an approved designee is responsible for checking all work performed and verifying that the work satisfies the applicable tasks required by this procedure. This verification will be accomplished by reviewing all documents and data produced during work performance.

## 3.0 GENERAL REQUIREMENTS

All work will be performed in accordance with the project-specific planning documents. Refer to the project-specific health and safety plan for relevant health and safety requirements.

Any deviations from specified requirements will be justified to and authorized by the project manager and/or the relevant program manager and documented in the approved project plans. Deviations from requirements will be sufficiently documented to re-create the modified process.

## 4.0 SAMPLING EQUIPMENT AND TECHNIQUES

Sediment samples may be obtained using on-shore or off-shore techniques. Sediment sampling equipment and techniques must be designed to minimize the risk of dilution or loss of material as the sample is moved through the water column. Sediment sampling devices are described below.

### 4.1 DIP SAMPLERS

A dip sampler consists of a pole with a jar or scoop attached. The pole may be made of bamboo, wood, Teflon<sup>®</sup>, or aluminum and be either telescoping or of fixed length. The scoop or jar at the end of the pole is attached by a clamp.

<b>Sediment Sampling</b>	<b>SOP No.: 403.08 (formerly 2.15)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: March 25, 2020</b>
	<b>Review Date: March 2022</b>

The dip sampler is operated by submerging the jar or scoop and pulling it through the sediments to be sampled. The samples retrieved are then transferred into the appropriate sample container after decanting the liquid. Further decanting can occur while the sample is present in the sample jar. Avoid contact with sampler's gloves. Transferring the sample may require the use of a stainless steel or Teflon<sup>®</sup> spoon/spatula.

## **4.2 HAND-OPERATED CORE SAMPLERS**

Hand-operated sediment core samplers are used to obtain sediment samples in shallow water (less than 3 feet). These samplers operate in a manner similar to soil core samplers. However, because of the saturated conditions of most sediments, provisions must be made to retain the sample within the core. Core samplers are generally constructed of a rigid metal outer tube into which a 2-inch plastic core sleeve fits with minimum clearance. The cutting edge of the core sampler has a recessed lip on which the plastic sleeve rests and that can accommodate a core retainer. This retainer is oriented such that when the sampler is pressed into the sediment, the core is free to move past the retainer. Due to construction of the retainer, the core will not fall through the retainer upon removal of the sampler from the sediment. Some core samplers are also equipped with a butterfly valve below the core barrel that helps retain the material when the sampler is removed from the sediment.

After the sampler has been removed from the sediment, the plastic sleeve is removed. The sediment is removed from the sleeve and placed in the appropriate sample container. Chlorinated organics will not be collected using core samplers because core sleeves and retainers are generally made of plastic. The hand-operated core sampler will not be useful for obtaining samples of gravelly, stony, or consolidated sediments. Examples of hand-operated core samplers are referenced in Attachment 1.

## **4.3 GRAVITY CORE SAMPLERS**

Gravity core samplers are used to obtain sediment samples in water bodies or lagoons with depths greater than 3 to 5 feet. These types of samplers can be used for collecting 1- to 2-foot cores of surface sediments at depths of up to 100 feet beneath the water surface.

As with all core-type samplers, gravity core samplers are not suitable for obtaining samples of coarse, gravelly, stony, or consolidated deposits. They are, however, useful for fine-grained inorganic sediment sampling.

The gravity core sampler operates in a manner similar to the hand-operated core in that a 2-inch plastic sleeve fits within a metal core housing fitted with a cutting edge. Plastic nests are used to retain the core within the plastic sleeve. An opening exists above the core sleeve to allow free flow of water into and through the core as it moves vertically downward to the sediment. The sampler has a field personnel-operated, messenger-activated valve assembly that seals the opening above the plastic sleeve following sediment penetration. This valve is activated by the messenger, creating a partial vacuum to assist in sample retention during retrieval.

<b>Sediment Sampling</b>	<b>SOP No.: 403.08 (formerly 2.15)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: March 25, 2020</b>
	<b>Review Date: March 2022</b>

Samples are obtained by allowing the sampler, which is attached to approximately 100 feet of stainless steel aircraft cable, to drop to the benthic deposits. The weight of the sampler drives the core into the sediment to varying depths depending on the characteristics of the sediments. The messenger is then dropped by field personnel on the taut aircraft cable to seal the opening above the plastic sleeve. The sampler is then carefully retrieved.

Upon retrieval of the sampler, the plastic core sleeve is removed and the sample is placed in the appropriate sample container. Care should be exercised in labeling to properly identify sample orientation. Examples of gravity core samplers are referenced in Attachment 2.

#### **4.4 DREDGES**

Dredges are generally used to sample sediments that cannot easily be obtained using coring devices or when large quantities of materials are required. Various dredge designs are available for sampling in deep or turbulent waters and for obtaining samples from gravelly, stony, or dense deposits.

Dredges generally consist of a clam shell arrangement of two buckets. The buckets may either close upon impact or be activated by use of a messenger. Dredges are commonly quite heavy and may require use of a winch and crane assembly for sample retrieval.

Upon retrieval of the dredge, the sample can either be sieved or transferred directly to a sample container for labeling and storage. Examples of dredge types that could be used for sampling include Ponar, Petersen, and Ekman dredges, which are referenced in Attachment 3.

#### **4.5 HAND AUGERS**

Sediment samples may be collected using a hand auger. When using a hand auger, provisions must be made to ensure that sediment samples remain in the auger. Hand augers are best utilized when sampling non-subaqueous sediments. Additional information on hand augers can be found in SOP 403.06: *Surface and Shallow Depth Soil Sampling*.

### **5.0 PROCEDURES**

#### **5.1 SAMPLING SEDIMENT WITH NO OVERLYING SURFACE WATER**

Sediment samples obtained from areas with no overlying surface water will be collected in accordance with the following procedures:

- Record all data in the field logbooks in accordance with SOP 300.04: *Field Logbook Use and Maintenance*.

<b>Sediment Sampling</b>	<b>SOP No.: 403.08 (formerly 2.15)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: March 25, 2020</b>
	<b>Review Date: March 2022</b>

- Insert a decontaminated Teflon<sup>®</sup> or stainless steel spoon, scoop, or trowel into the sediment to the desired depth and remove the collected sample, or rotate and push down a decontaminated hand auger into the sediment to the desired depth and remove the collected sample. A disposable scoop may be used for specified media and analytical parameters in accordance with the site-specific project plans.
- Collect samples for volatile organic compounds (VOC) analyses, if applicable, from the sampling device or from unmixed sediment placed into a stainless steel bowl in accordance with SOP 403.01: *VOC Soil Sample Collection*.
- Place the sample in a decontaminated stainless steel bowl. Stir the sample thoroughly (non-VOC samples only) with a decontaminated stainless steel spoon or spatula—or with a dedicated disposable scoop—to provide a homogeneous mixture before filling sampling containers.
- Follow the guidelines in the site-specific project plans and Quality Assurance Project Plan (QAPP) for aliquot size (mass), container type, storage conditions, and holding times. [Note: When sampling in coarse materials, such as gravel, discretion must be used to limit inclusion of large sediment particles. As the analysis of sediments performed by the laboratory is typically restricted to particles less than 2 millimeters in size, care must be taken to ensure that there is sufficient sample volume consisting of particles smaller than 2 millimeters. As a general rule, particles larger than 0.5 inch (12.7 millimeters) in size should be excluded unless a grain size analysis is planned.] Fill the appropriate sample containers as detailed in the site-specific project plans. Identify or label samples carefully and clearly, addressing all the categories or parameters.
- Label the sample containers and place the filled sample containers on ice immediately.
- Decontaminate the sampling equipment in accordance with SOP 411.02: *Sampling Equipment Cleaning and Decontamination*, after use and between sampling if dedicated disposable scoops are not used. Don new clean gloves before beginning sampling activities and at each sampling point.
- Complete all chain of custody documents and record information in the Field Sampling Report (Attachment 4) and the field logbook (see the project-specific QAPP for sample custody procedures).

## 5.2 SHALLOW STREAM SEDIMENT SAMPLING

Stream sediment sampling within shallow (less than 2 feet) water will be conducted in accordance with the following procedures. Note that if co-located surface water samples are being collected, the surface water sample should be collected first.

- Collect the sample in an area of sediment accumulation, such as the inside of stream meanders, quiet shallow areas, and low-velocity zones. Avoid areas of net erosion, such as high-velocity, turbulent flow zones.

<b>Sediment Sampling</b>	<b>SOP No.: 403.08 (formerly 2.15)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: March 25, 2020</b>
	<b>Review Date: March 2022</b>

- If possible, collect the sample while remaining on the stream bank. If the sample cannot be obtained from the bank, enter the stream from a point downstream of the sediment sampling location. Consult the site health and safety plan before entering the river to avoid potential hazards. Collect the sediment sample by reaching into the stream with a decontaminated stainless steel spoon or Teflon<sup>®</sup> scoop and scooping a sample in an upstream direction. Attempt to minimize the loss of fine material. A disposable scoop may be used for specified media and analytical parameters, in accordance with the site-specific project plans.
- Collect samples for VOC analyses, if applicable, from the sampling device or from unmixed sediment placed into a stainless steel bowl in accordance with SOP 403.01: *VOC Soil Sample Collection*.
- Place sample in a stainless steel bowl and gently mix with a stainless steel spoon or dedicated disposable scoop (non-VOC samples only). Transfer the sediment samples to the appropriate sample containers using the stainless steel spoon or dedicated disposable scoop. Do not mix samples for volatile organic analyses.
- Follow the guidelines in the site-specific project plans and QAPP for aliquot size (mass), container type, storage conditions, and holding times. See note under Section 5.1 for sampling coarse materials. Fill the appropriate sample containers as detailed in the site-specific project plans. Identify or label samples carefully and clearly, addressing all the categories or parameters.
- Decontaminate the sampling equipment in accordance with SOP 411.02: *Sampling Equipment Cleaning and Decontamination*, after use and between sampling if dedicated disposable scoops are not used. Don new clean gloves before beginning sampling activities and at each sampling point.
- Complete all chain of custody documents and record information in the Field Sampling Report (Attachment 4) and the field logbook (see the project-specific QAPP for sample custody procedures).

### 5.3 SUBAQUEOUS SEDIMENT SAMPLING

Subaqueous sediment sampling from lakes, ponds, lagoons, and surface impoundments will consist of the following:

- Select the most appropriate sediment sampling device (as described in Section 4.0).
- Decontaminate all sampling equipment in accordance with SOP 411.02: *Sampling Equipment Cleaning and Decontamination*.
- If sampling from a boat equipped with an engine, attempt to collect the sample with the boat engine off or attempt to ensure that all exhaust fumes are directed away from the sample collection area until the sample has been collected.

<b>Sediment Sampling</b>	<b>SOP No.: 403.08 (formerly 2.15)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: March 25, 2020</b>
	<b>Review Date: March 2022</b>

- Lower the sampler at a controlled descent of approximately 1 foot per second until the sampler reaches the sediment surface, as indicated by a slackening of the cable. Release the weighted messenger, if applicable, to engage the closing mechanism of the dredge. Slowly retrieve the sampler and raise it at a controlled speed. When the sampler is at the water surface, attach a tag line(s) to steady and pull the sampler back into the boat. If large samplers are used, a motorized winch may be required for retrieval.
- Open and tie back any vent flaps on the sampler and carefully siphon off any overlying water, disposing of it over the side of the boat.
- Visually inspect the sample for acceptability (for example, determine if an undisturbed surface layer is evident, the overlying water is not excessively turbid, and adequate penetration is achieved). If the sample is not acceptable, discard it and collect another sample from an adjacent and upstream location.
- Carefully extrude the sediment from the sampler by slowly lifting on the winch cable and sliding the sample out the bottom of the sampler. If using core liners, remove the front face of the core liner to expose the side of the core.
- Visually inspect the side of the sample to identify any obvious stratification (such as different sediment types, sizes, or colors). If no patterns are evident, collect a sample from the surface and mid-core depth. During some investigations, it may be necessary to collect separate samples from the surface and mid-core depths. This may best be accomplished by gently scraping the side of the core with a decontaminated stainless steel scraper or knife. Scrape from the bottom to the top of the core only. If the sediment is unconsolidated, do not scrape.
- Remove the upper 2 centimeters of the sample using a decontaminated Teflon<sup>®</sup> or stainless steel scoop—or dedicated disposable scoop—and place it in the sample container. From an undisturbed area of the sample surface, scoop a 2-centimeter sample only if grain size analysis is required. After grain size analysis samples are collected, scrape off the upper sediment layer and discard it overboard. Collect samples from the mid-section of the sediment. Sediment must be removed with caution to avoid cross-contaminating the sample (that is, from exposure to engine exhaust, rust, or grease).
- Do not include nonrepresentative materials, such as twigs or debris, in the sample. Do not include sediments that have come into contact with the side of the sampler or core liner for analysis.
- Follow the guidelines in the site-specific project plans and QAPP for aliquot size (mass), container type, storage conditions, and holding times. Fill the appropriate sample containers as detailed in the site-specific project plans. Identify or label samples carefully and clearly, addressing all the categories or parameters;
- Decontaminate the sampling equipment in accordance with SOP 411.02: *Sampling Equipment Cleaning and Decontamination* after use and between sampling if dedicated

<b>Sediment Sampling</b>	<b>SOP No.: 403.08 (formerly 2.15)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 2</b>
	<b>Revision Date: March 25, 2020</b>
	<b>Review Date: March 2022</b>

disposable scoops are not used. Don new clean gloves before beginning sampling activities and at each sampling point.

- Complete all chain of custody documents and record information in the Field Sampling Report (Attachment 4) and the field logbook (see the project-specific QAPP for sample custody procedures).

## 6.0 RECORDS

Documentation generated as a result of this procedure is collected and maintained in accordance with requirements detailed in the project-specific planning documents. The field logbook will be completed in accordance with procedures listed in SOP 300.04: *Field Logbook Use and Maintenance*. A Field Sampling Report will be filled out for each sediment sample collected (Attachment 4).

## 7.0 REVISION HISTORY

Revision 0	December 2010	Initial Release
Revision 1	August 11, 2017	Updated to incorporate lessons learned on the process and to reflect changes in SOP formatting.
Revision 2	February 25, 2020	Updated to incorporate lessons learned on the process and to reflect changes in SOP formatting, which included changing the SOP number from 2.15 to 403.08.

**SOP 411.02, SIB Project Area, PHSS**  
**(Source: Sampling Equipment Cleaning and Decontamination)**

	<b>STANDARD OPERATING PROCEDURE</b>	
	Approved by: <b>Dick, Jeff</b>	<small>Digitally signed by Dick, Jeff Date: 2020.06.18 16:05:40 -04'00'</small> <b>Corporate Quality Manager</b>
<b>Sampling Equipment Cleaning and Decontamination</b>	<b>SOP No.: 411.02 (formerly 2.01)</b>	
	<b>SOP Category: Environmental Services</b>	
	<b>Revision No.: 5</b>	
	<b>Revision Date: June 18, 2020</b>	
	<b>Review Date: June 2022</b>	

## 1.0 PURPOSE

The purpose of this standard operating procedure (SOP) is to describe field methods to be used for cleaning and decontaminating sampling equipment.

This procedure is specifically applicable to sampling equipment that has been used to collect environmental samples or could have been exposed to contamination that could affect worker safety and/or the integrity of the analytical results of the media sampled.

Other decontamination procedures may apply to a specific project; refer to the project-specific planning documents for project-specific decontamination methods and schedules.

Any deviations from specified requirements must be justified to and authorized by the project manager and/or the relevant program manager and discussed in the approved project plans. Deviations from requirements are documented sufficiently to re-create the modified process.

## 2.0 SUMMARY OF THE METHOD

This SOP describes the procedures to be followed to achieve effective decontamination as follows: (1) remove contaminants from contaminated surfaces, (2) minimize the spread of contamination to uncontaminated surfaces, (3) avoid any cross-contamination of samples, and (4) minimize personnel exposures. The intent is to accomplish the required level of decontamination while minimizing the generation of additional solid and liquid waste.

## 3.0 DEFINITIONS

*ASTM Type II Water:* This is the type of deionized reagent grade water, as defined by ASTM International, used in the final rinse of surfaces of contaminated equipment.

*Equipment:* Equipment comprises those items (variously referred to as “field equipment” or “sampling equipment”) that are necessary to conduct sampling activities but that do not directly contact the samples.

*Laboratory Detergent:* This is a standard brand of phosphate-free laboratory detergent such as Liquinox® or Luminox®. Liquinox® is a traditional anionic laboratory detergent used for general cleaning and when there is concern that harsher cleaners could affect the stability of the sampling equipment. Luminox® is a specialized detergent that can remove oils and organic contamination. It may be used in lieu of a solvent rinse step in cleaning equipment for trace contaminant sampling.

<b>Sampling Equipment Cleaning and Decontamination</b>	<b>SOP No.: 411.02 (formerly 2.01)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 5</b>
	<b>Revision Date: June 18, 2020</b>
	<b>Review Date: June 2022</b>

Where not specified in these procedures, either detergent is acceptable. The project-specific plans should indicate if Luminox® use is acceptable.

*Organic-free Water:* This is tap water that has been treated with activated carbon and deionizing units. At a minimum, the finished water must meet the analytical criteria of deionized water, and it should contain no detectable pesticides, herbicides, or extractable organic compounds and no volatile organic compounds above minimum detectable levels for a given set of analyses. Organic-free water obtained by other methods is acceptable as long as it meets the above analytical criteria.

*Potable/Tap Water:* Potable/tap water is provided by local city sources and is safe for consumption. Chemical analysis of the water source is not required before it is used. Deionized water or organic-free water may be substituted for tap water.

*Sampling Devices:* This is equipment used to acquire samples.

## 4.0 GENERAL REQUIREMENTS

All work is performed in accordance with the project-specific planning documents. Refer to the project-specific health and safety plan for relevant health and safety requirements. Any deviations from specified requirements must be justified to and authorized by the project manager and/or the relevant program manager. Deviations from requirements are documented sufficiently to re-create the modified process.

## 5.0 EQUIPMENT AND SUPPLIES

The following equipment is specific to decontamination requirements and does not include required safety equipment and field documentation described in the site-specific plans. Project-specific plans should be consulted for any additional equipment or deviations from the list below:

- Laboratory detergent,
- Brushes (not wire wound),
- Paper towels/rags,
- Squirt bottles (one for each decontamination fluid),
- 5-gallon buckets or decontamination pad/kiddie pool to contain decontamination fluids,
- Potable water,
- Deionized water,
- Drums or containers for decontamination fluids/solids,
- Drum/container waste labels,
- Sampling containers for decontamination fluid/solid sampling,
- Aluminum foil,
- Steam cleaner, and
- Generator and fuel.

<b>Sampling Equipment Cleaning and Decontamination</b>	<b>SOP No.: 411.02 (formerly 2.01)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 5</b>
	<b>Revision Date: June 18, 2020</b>
	<b>Review Date: June 2022</b>

## 6.0 PROCEDURAL STEPS

Decontamination of sampling devices is performed in a designated decontamination area, removed from any sampling or dedicated office location. This designated area must be in a location free of direct exposure to airborne and radiological surface contaminants and upwind of any field activities that could jeopardize the decontamination procedures or cross contaminate the cleaned equipment.

### 6.1 GENERAL

The following general rules are followed for decontamination operations:

- Contaminated or dirty sampling devices/equipment should not be stored with or above clean (decontaminated) sampling devices/equipment.
- Clean, decontaminated sampling devices should be segregated from all other equipment and supplies.
- Paint or any other coatings must be removed from any part of a sampling device that may either contact a sample or may otherwise affect sample integrity. After such coatings are removed, the sampling device must be decontaminated using the appropriate method.
- For any of the specific decontamination methods that may be used, the substitution of higher-grade water is permitted (for example, using deionized water in place of tap water). However, deionized water is less effective than tap water in rinsing away detergent during the initial rinse.
- Decontaminated sampling devices and all filled and empty sample containers are stored in locations protected from exposure to any contaminant.
- The method for decontaminating sampling devices and the exterior of sample containers that have been exposed to radioactive material is based on the material contaminated, the sample medium, the radiation levels, and the specific radionuclides to be removed.
- The release of decontaminated sampling devices and sample containers for unrestricted use is based on site-specific criteria. These site-specific criteria should be detailed in the project-specific plans.
- Rags/paper towels used during decontamination activities may become a hazardous waste and require segregation. Refer to the project-specific plans for hazardous waste disposal requirements.
- Sampling devices must be decontaminated before being used in the field to prevent potential cross-contamination of a sample.
- Sampling devices must be decontaminated between samples to prevent cross-contamination.

<b>Sampling Equipment Cleaning and Decontamination</b>	<b>SOP No.: 411.02 (formerly 2.01)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 5</b>
	<b>Revision Date: June 18, 2020</b>
	<b>Review Date: June 2022</b>

- Sampling devices must be decontaminated at the close of the sampling event before being taken off site.
- An acceptable alternative to cleaning and decontaminating sampling devices is using items cleaned or sterilized by the manufacturer that are discarded after one use. Care must be exercised to ensure that such previously cleaned or sterilized items do not retain residues of chemical or radioactive sterilizing agents that might interfere with analytical techniques.
- Whenever visible dirt, droplets of liquid, stains, or other extraneous materials are detected on the exterior of a sample container, the exterior surfaces must be decontaminated. This step should be performed before the container is placed in a sample cooler or shipping container.
- For sample containers used in controlled access areas, more rigorous cleaning and/or radiation monitoring may be required before removal from the site. Refer to the project-specific planning documents for details.
- Decontamination fluids/solids as well as other used cleaning supplies, such as paper towels and rags, should be treated as investigation-derived waste and managed in accordance with the project-specific planning documents.

## 6.2 DECONTAMINATION METHODS

The following decontamination methods are examples of some of those most commonly used in field investigations. Note that the decontamination methods described in this section are for guidance only; the project-specific planning documents and the SOPs referenced in them provide the actual procedures that must be followed. The field operations manager may need to adjust decontamination practices to fit the sampling situation and applicable requirements. All variances from the project-specific planning documents must be approved by the project manager in advance and documented. Procedures for packaging and disposing of all waste generated during decontamination are described in the project-specific planning documents.

### 6.2.1 Water Level Indicators

The following steps are taken to decontaminate water level indicators. Unless conditions warrant, it is only necessary to decontaminate the wetted portion of the measuring tape. It may be more practical to decontaminate the tape as it is being rewound, but with the reel several feet away from the wellhead (see project-specific planning documents):

1. Wash with detergent and tap water.
2. Rinse with tap water.
3. Rinse with deionized water.

<b>Sampling Equipment Cleaning and Decontamination</b>	SOP No.: 411.02 (formerly 2.01)

	Review Date: June 2022

### 6.2.2 Submersible Groundwater Pumps

The following procedures are taken to decontaminate submersible pumps used to collect groundwater samples. This is the general procedure for non-dedicated pumps, unless the dedicated pump is being removed from the well.

1. Disconnect and discard the previously used tubing from the pump. Wash the pump exterior with detergent and water.
2. Prepare and fill three containers with decontamination solutions consisting of Container 1, tap water and detergent solution; Container 2, a tap water rinsing solution; and Container 3, a deionized water final rinsing solution. The containers should be large enough to hold the pump and 1 to 2 liters of solution. An array of 2-foot-long 2-inch PVC pipes with bottom caps is a common arrangement. Buckets can also be used as long as the water covers the intake screen of the pump. The containers should be labeled to ensure that decontamination is completed in the correct steps. The solutions should be changed at least daily.
3. Place the pump in Container 1. Turn the pump on and circulate the detergent and water solution through the pump and then turn the pump off.
4. Place the pump in Container 2. Turn the pump on and circulate the tap water through the pump and then turn the pump off.
5. Place the pump in container 3. Turn the pump on and circulate the deionized water through the pump and then turn the pump off.
6. Disconnect the power and remove the pump from Container 3.
7. Decontaminate the power lead by washing it with detergent and water, followed by tap water and a deionized water rinse. This step may be performed before washing the pump, if desired.
8. Wind the power lead back on a reel, and place the pump and reel in a clean plastic bag.

### 6.2.3 Bladder Pumps

The following procedures are used to decontaminate bladder pumps that use disposable bladders. If the bladder pump being used does not have a disposable bladder, the decontamination procedures outlined in Section 6.2.2 should be used.

1. Disconnect and discard previously used tubing from the pump.
2. Completely disassemble the pump, being careful not to lose the check balls, O-rings, ferrules, or other small parts.
3. Remove and discard the pump bladder.

<b>Sampling Equipment Cleaning and Decontamination</b>	<b>SOP No.: 411.02 (formerly 2.01)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 5</b>
	<b>Revision Date: June 18, 2020</b>
	<b>Review Date: June 2022</b>

4. Clean all parts with tap water and detergent, using a brush if necessary to remove particulate matter and surface films.
5. Rinse thoroughly with tap water.
6. Rinse thoroughly with deionized water.
7. Install a new pump bladder.
8. Reassemble the pump and wrap it in aluminum foil or store it in a decontaminated pump storage tube.

#### **6.2.4 Small Tools/Samplers**

The following procedures are used to decontaminate small tools/samplers (e.g., stainless steel bowls, sample trowels, and hand augers).

1. Wash the tools/samplers with detergent and tap water, using a brush to remove particulate matter and surface film.
2. Rinse thoroughly with tap water.
3. Rinse thoroughly with deionized water.
4. Wrap the tools/samplers in aluminum foil or place them in a clean plastic bag.

#### **6.2.5 Drilling and Direct-Push Technology Sampling Equipment**

These procedures are used for drilling and direct-push technology (DPT) sampling activities involving the construction of monitoring wells to be used for collecting groundwater samples or for collecting soil and groundwater samples.

##### **6.2.5.1 Drill and DPT Rig**

Any portion of the drill or DPT rig or backhoe over the borehole or sample location that has come into contact with soil or groundwater (mast, backhoe bucket, drilling platform, hoist, cathead) should be steam cleaned (detergent and high-pressure hot water) between boreholes or sample locations. A decontamination pad should be constructed as specified in the project-specific plans to contain soil and decontamination fluids.

##### **6.2.5.2 Downhole Drilling and DPT Equipment**

The following is the standard procedure for field cleaning augers, drill stems, rods, tools, and associated equipment.

1. Wash the equipment with tap water and detergent, using a brush if necessary to remove particulate matter and surface film. Steam cleaning may be necessary to remove matter that

<b>Sampling Equipment Cleaning and Decontamination</b>	<b>SOP No.: 411.02 (formerly 2.01)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 5</b>
	<b>Revision Date: June 18, 2020</b>
	<b>Review Date: June 2022</b>

is difficult to remove with the brush. Drilling equipment that is steam cleaned should be placed on racks above the floor of the decontamination pad. Hollow-stem augers, drill rods, drive casing, and other equipment that is hollow or has holes that transmit water or drilling fluids should be cleaned on the inside with vigorous brushing or steam cleaning.

2. Rinse the equipment with tap water.
3. Remove the equipment from the decontamination pad and cover it with clean plastic or reinstall the equipment on the drill rig.

### 6.3 QUALITY CONTROL

The effectiveness of the decontamination procedures is monitored by submitting samples of rinse water to the laboratory for low-level analyses of the parameters of interest, also referred to as equipment blanks. An attempt should be made to select different sampling devices each time devices are decontaminated to ensure that a representative sampling of all devices is obtained over the length of the project. Equipment blanks should be collected as specified in the project-specific planning documents.

### 7.0 RECORDS

Documentation generated as a result of this procedure is collected and recorded in a field logbook in accordance with procedures listed in SOP 300.04: *Field Logbook Use and Maintenance*.

### 8.0 REVISION HISTORY

Revision 0		Initial Release
Revision 1	December 2010	Updated to incorporate lessons learned on the process and to reflect changes in SOP formatting.
Revision 2		Updated to incorporate lessons learned on the process and to reflect changes in SOP formatting.
Revision 3	July 2017	Updated to incorporate lessons learned on the process and to reflect changes in SOP formatting.
Revision 4	February 2018	Updated to incorporate lessons learned on the process and to reflect changes in SOP formatting.
Revision 5	June 18, 2020	Updated to incorporate lessons learned on the process and to reflect changes in SOP formatting, which included changing the SOP number from 2.01 to 411.02.

**SOP 411.03, SIB Project Area, PHSS  
(Source: Subsurface Utility Avoidance)**

	<b>STANDARD OPERATING PROCEDURE</b>	
	Approved by:	Corporate Quality Manager
<b>Subsurface Utility Avoidance</b>	SOP No.: 411.03 (formerly 401.01)	
	SOP Category: Environmental Services	
	Revision No.: 3	
	Revision Date: September 29, 2020	
	Review Date: September 2022	

## 1.0 SCOPE AND APPLICABILITY

This procedure applies to work that involves penetrating the soil surface with powered equipment during drilling or excavation activities. It is permissible to use a client’s or facility owner/operator’s utility avoidance procedure in lieu of this procedure if it provides equivalent protection.

For overhead utility lines avoidance, see the following procedures:

- HGL H&S Procedure 21: *Excavation and Trenching*,
- HGL H&S Procedure 27: *Drilling Safety*,
- HGL H&S Procedure 32: *Aerial Lift and Elevated Work Platform*, and
- HGL H&S Procedure 40: *Forklifts and Earthmoving Equipment*.

### 1.1 SUMMARY OF METHOD

This procedure establishes the minimum requirements for avoiding damage to subsurface utilities from unintentional contact with powered equipment.

### 1.2 HEALTH AND SAFETY WARNINGS

This procedure is not intended to address the hazards associated with subsurface investigation activities. Consult HGL Health and Safety (H&S) Procedure 21: *Excavation and Trenching* and Procedure 27: *Drilling Safety* for safety guidance and requirements. Do not perform intrusive work in areas that may contain unexploded ordnance (UXO) without a UXO escort and clearance by qualified UXO personnel.

Follow the procedures below if a utility is damaged during work (refer to the project Health and Safety Plan or Accident Prevention Plan for project contact information):

- If a gas line has been breached, shut down all nearby equipment that might provide an ignition source.
- Evacuate the immediate area of the breach unless the breached item clearly poses no hazard to personnel, as determined by the Site Safety and Health Officer (SSHO).
- Notify the owner/manager of the utility and emergency services (as appropriate) immediately. Note that in many cases contacting the public utility locating service (using One Call, calling 811, or going online to <https://call811.com>) will notify the member utility. In some states it is required by law to notify the One Call service.

<b>Subsurface Utility Avoidance</b>	<b>SOP No.: 411.03 (formerly 401.01)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 3</b>
	<b>Revision Date: September 29, 2020</b>
	<b>Review Date: September 2022</b>

- If a buried electrical line is cut or damaged, call the power company emergency number for instructions.
- Notify the HGL Project Manager and H&S Director.
- Do not proceed with activities until the situation has been assessed by qualified H&S or utility owner personnel and written permission to resume work has been granted by the Project Manager and H&S Director.

### **1.3 PERSONNEL RESPONSIBILITIES**

The Project Manager is responsible for the following:

- Obtaining any facility-specific requirements/procedures for intrusive work, such as a dig permit;
- Obtaining specifications and “as-built” drawings for any buried lines, utilities, tanks, or other structures at the site and reviewing the proposed locations for drilling or excavation relative to those structures;
- Verifying that if client or facility utility avoidance procedures are to be used, they provide protection that is equivalent to that provided by this HGL SOP;
- Arranging for additional utility location beyond One Call service, such as private utility locating subcontractors, if
  - No accurate utility maps or “as-built” drawings are available,
  - Work is being performed close to high-value or high-hazard buried utilities, or
  - Work is being performed in residential areas, inside buildings, outside of public rights-of-way, or in other locations where unmapped utilities may be present.
- Arranging for UXO escort and UXO clearance if unexploded ordnance may be present;
- Ensuring that utility owner/manager emergency phone numbers are in emergency contact lists; and
- Ensuring that arrangements and procedures for subsurface utility avoidance are addressed during the pre-mobilization readiness review. These include establishing procedures for intrusive activities within 5 feet of a utility; arranging for HGL not to be responsible for damages to subsurface utilities in accordance with the One Call service or facility liability provisions; and obtaining a written waiver from the client or site owner, if needed.

The Field Manager is responsible for the following:

- Contacting the state utility One Call service and/or facility utility program to locate and mark subsurface utilities and hazards at the worksite and to update them during the duration of the work;

<b>Subsurface Utility Avoidance</b>	<b>SOP No.: 411.03 (formerly 401.01)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 3</b>
	<b>Revision Date: September 29, 2020</b>
	<b>Review Date: September 2022</b>

- Completing the utility avoidance checklist attached to this SOP before the start of intrusive work;
- Ensuring that fieldwork involving powered drilling or excavation follows this procedure and other applicable requirements including HGL H&S procedures;
- Ensuring that site personnel are trained on the requirements of this SOP;
- Discussing utility-related emergency procedures in the pre-mobilization readiness review and daily safety briefings;
- Ensuring that all drilling or excavation locations are marked using high-visibility paint or some other recognizable and durable marking;
- Reviewing utility maps against field markings and resolving any inconsistencies or questions with the One Call service or facility utility program;
- Verifying at the start of each workday that drilling/excavation and utility markings are intact and clear, and contacting the One Call service or facility utility program to re-mark utilities if necessary;
- Understanding the utility incident reporting requirements for the state and facility where the work is done; and
- Reporting immediately any unintentional contact or damage to subsurface assets or hazards.

#### **1.4 DATA AND RECORDS MANAGEMENT**

Steps taken to avoid damaging utilities must be documented in the appropriate records such as the utility avoidance checklist, pre-drilling checklist, inspection checklist from H&S Procedure 21, field logbooks, and photographs, including photographs of the utility marks relative to the boring/excavation prior to the start of intrusive activities. Copies of utility maps, completed dig permits, and other relevant documentation must be kept at the project site and in the project files.

## **2.0 PROCEDURE**

The Field Manager is responsible for executing this procedure on the project site and completing the Utility Avoidance Checklist in Attachment 1 before the start of intrusive work.

Before commencing intrusive work using powered equipment, contact the public utility locating service (using One Call, calling 811, or going online to <https://call811.com>), the facility’s utility program, or a private utility contractor. Utilities not in the public right-of-way are typically not marked by the One Call service.

<b>Subsurface Utility Avoidance</b>	<b>SOP No.: 411.03 (formerly 401.01)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 3</b>
	<b>Revision Date: September 29, 2020</b>
	<b>Review Date: September 2022</b>

Complete a walk-over survey of excavation or drilling locations prior to intrusive activities and then visually confirm that known utilities have been marked as appropriate and that markings are consistent with visible cues of possible subsurface utilities including the following:

- Utility posts/line markers,
- Water shutoff valves,
- Sewer cleanouts/manhole covers,
- Discharge pipes,
- Stormwater inlets,
- Irrigation wells and pivots,
- Fire hydrants (hydrants are typically offset from the water main by several feet),
- Junction boxes,
- Electrical poles with conduit into the subsurface,
- Light poles,
- Storage tank vents,
- Transformers, and
- Cuts/patches in pavement.

Determine if proposed drilling or excavation locations are immediately between storage tanks and product dispenser systems, between storage tanks and control units or buildings, between underground storage tanks and tank air vents, between manholes and sewer connections, or between any features that are likely to be connected by a subsurface utility, and if they are, relocate the drilling/excavation locations if possible. Identify facility assets (for example, equipment, control centers, fire suppression systems, vital communication systems, hospitals, police stations) that may be impacted or harmed if a utility is breached. Know the location of any shutoff valves in the area (for example, irrigation lines). Take photographs of all drilling and excavation locations prior to, during, and after work is complete.

Contact the One Call service or facility utility program if a utility is encountered that has not been marked or communicated to complete the locate and marking for that utility. If a utility is encountered and has not been marked or communicated by the One Call service or facility utility program, notify the Project Manager and H&S Director, who will determine the next step, such as arranging an independent utility survey and notifying the One Call service or facility utility program of the failure.

If a planned intrusive location is within 5 feet of a utility, reposition the work if feasible and request a new utility clearance by the One Call service. Consult the Project Manager before deciding to relocate a planned drilling or excavation location; obtain client approval if necessary. Keep in mind that many utility markings are approximations and that the utilities may be several feet from the markings.

<b>Subsurface Utility Avoidance</b>	<b>SOP No.: 411.03 (formerly 401.01)</b>
	<b>SOP Category: Environmental Services</b>
	<b>Revision No.: 3</b>
	<b>Revision Date: September 29, 2020</b>
	<b>Review Date: September 2022</b>

For drilling operations, if it is not feasible to relocate the drilling location, excavate at least the first 5 feet (deeper if it is likely that there are deeper utilities) of boreholes with a low-impact technique such as hand augering, hydrovacating, or air knifing. Pre-excavation of boreholes using low-impact techniques must also be performed under the following conditions:

- The location of utilities is uncertain.
- The work is being done in a residential or high population commercial area.

It is permissible to omit low-impact pre-excavation of boreholes under the following conditions:

- It has been verified that no hazardous (for example, gas, liquid fuel, or electric) or mission-critical communication (for example, fiber optic) subsurface utilities exist within 25 feet of the planned drilling location and that HGL will not be responsible for damages to subsurface utilities in accordance with the One Call service or facility liability provisions; or
- A written waiver has been obtained from the client or site owner.

Situations that do not fit the above criteria should be resolved at the pre-mobilization readiness review. Decisions to forego low-impact pre-excavation of drilling boreholes are subject to Program Manager approval through the issuance of a Subsurface Utility Avoidance memorandum or Field Work Variance. The memorandum must detail the justification to forgo the procedures outlined in this SOP, H&S Procedure 21: *Excavation and Trenching* and H&S Procedure 27: *Drilling Safety*. The revised procedure must be discussed during the readiness review meeting with all task participants, and the signed memorandum must be included with the readiness review form and/or pre-drilling checklist.

Criteria for determining the need to pre-excavate boreholes are summarized below:

<b>Criterion</b>	<b>Utility Location</b>	<b>Other Condition</b>	<b>Decision</b>
a	Within 5 feet		Pre-excavate
b	Between 5 and 25 feet	Uncertain if utilities are present	Pre-excavate
c	More than 25 feet	No hazardous or high-value utilities are present	May skip pre-excavation
d	Uncertain	Residential or high-population commercial	Pre-excavate
e	Uncertain	No hazardous or high-value utilities are present; HGL liability waived	May skip pre-excavation
f	Uncertain	Not d or e	Site-specific; resolve at pre-mobilization readiness review and document in review minutes

<b>Subsurface Utility Avoidance</b>	SOP No.: 411.03 (formerly 401.01)
	SOP Category: Environmental Services
	Revision No.: 3
	Revision Date: September 29, 2020
	Review Date: September 2022

For excavation operations, if utilities are located within the planned excavation or within 5 feet of the limits of the excavation, the precise location of those utilities must be determined by excavating with low-impact tools such as hand auger, shovel, hydrovac or air knife. This may be necessary at several locations within the excavation area to confirm that the apparent route and depth of the utility do not change. **If a utility extends throughout the area to be excavated, the utility must be exposed to confirm its location and depth at least once every 10 feet. The utility must be exposed continuously, using low impact techniques, when performing powered excavation within 5 feet of the utility.**

HGL must inspect excavations managed by subcontractors at sufficient frequency and at least daily to confirm that the subcontractor is complying with these requirements and must require the subcontractor to make corrections if they are not in compliance.

If subsurface obstructions prevent reaching a depth of 5 feet using low-impact techniques, verify that the obstruction itself is not a utility (for example, a concrete sewer pipe versus concrete rubble). Conversely, if there is a credible probability that utilities are present at depths greater than 5 feet, the low-impact excavation may be continued to greater depths. **It is not permissible to omit low-impact excavation due to a lack of suitable equipment.**

Inspect the low-impact excavation and excavated material for indications of utilities, such as the edge of a pipe visible in the sidewall of the excavation or the presence of pea gravel that may be pipe bedding. If a subsurface utility is unintentionally encountered at any time during a low-impact or powered boring or excavation, cease all work in the immediate area and contact the SSHO and Field Manager.

Any material generated during pre-excavation activities is managed in accordance with the project-specific planning documents.

Maintain and protect markings for utility locations during the work. If utility markings are weathered away or removed, or if the location or boundaries of the activity change, repeat the locating processes and replace the markings. Many utility incidents occur when the boundaries of excavations are changed or the marked utility locations wear off.

## UTILITY AVOIDANCE CHECKLIST

Date: \_\_\_\_\_ Project/Site: \_\_\_\_\_

Field Manager: \_\_\_\_\_

Work to be Performed: \_\_\_\_\_

Consideration	Y	N	Explanation	Initial
1. Has a dig permit been obtained and approved?				
2. Has state One Call service been contacted?				
3. Has facility utility program been contacted?				
4. Has a private utility locating survey been conducted?				
5. Have as-built drawings been reviewed for utilities or subsurface hazards (e.g., USTs)?				
6. Has a visual inspection of the work area(s) been completed, including taking photographs?				
7. Have all known utilities and subsurface hazards been clearly marked?				
8. Has a visual inspection indicated the possible presence of other utilities or subsurface hazards?				
9. Are intrusive activities being conducted within 5 feet of a utility?				
10. If Item 9 is YES, can activity be relocated?				
11. Are any final drilling locations within 5 feet of a utility; are utility locations uncertain or working in residential or high population area? If YES, excavate first 5 feet using low-impact techniques				
12. Are any utilities within 5 feet of the excavation limits? If YES, determine precise location with low-impact techniques.				
13. Can drilling proceed WITHOUT excavating the upper 5 feet with low-impact techniques? Explain why.				
14. If working near overhead power lines, is a minimum clearance of 20 feet being maintained?				
15. Has written approval been granted by the Program Manager to deviate from SOP 411.03? Attach to checklist.				
Other considerations:				

**SOP A-1, SIB Project Area, PHSS  
(Source: Hydrocarbon Field Screening)**

# Standard Operating Procedure

## Hydrocarbon Field Screening by Sheen Test

### 1.0 Purpose and Applicability

The Standard Operating Procedure (SOP) for sheen test describes a procedure to visually estimate areas of possible hydrocarbon impacts in soil or sediment. In addition, screening results can be used to aid in the selection of soil/sediment samples for chemical analysis. The field screening method includes a visual examination and water jar screening test.

Visual screening consists of inspecting the soil/sediment for stains, nonaqueous-phase liquids (NAPL), and/or sheens indicative of residual hydrocarbons. Visual screening is most effective at detecting heavy hydrocarbons, such as creosote, free-phase NAPL or high hydrocarbon concentrations. Water sheen screening from a representative soil/sediment sample is a more sensitive method at detecting the presence of hydrocarbons.

### 2.0 Responsibilities

The project manager is responsible for ensuring that a properly designed sampling program is prepared prior to any sample collection. The field sampling coordinator will have the responsibility to oversee and ensure that all sampling is performed in accordance with the project-specific sampling program and this SOP. In addition, the field sampling coordinator must ensure that all field workers are fully apprised of this SOP.

### 3.0 Health and Safety

This section presents the potential hazards associated with this technique. The site-specific Health & Safety Plan (HASP) will take precedence over this document. Note that sample collection usually requires Level D personal protection unless there is a potential for airborne or dermal exposures to site contaminants.

Health and safety hazards include but are not limited to the following:

- Dermal exposure to potentially contaminated media: proper personal protective equipment (PPE) is used to mitigate dermal contact including the impact of splashes of water or media to skin and/or eyes;
- Inhalation exposure when handling impacted media: respiratory protection should follow the procedures outlined in the project Site-Specific HASP; and
- Broken glass, in the event that a glass jar is used: use care when handling glassware.

### 4.0 Supporting Materials

The following materials must be on hand in sufficient quantity to ensure that proper screening procedures may be followed:

- Approximately one cubic-inch of media to be screened;
- 4 of 8 oz. wide-mouth, clear glass jar;
- Stirring devise (i.e. spoon);
- Squirt bottle; and
- Supply of distilled water.

## 5.0 Methods and Procedures

The strategy used to collect soil/sediment samples in the field for sheen testing will depend on the nature/grain size of the material and the type of hydrocarbon. Discrete samples may be collected from specific depths where NAPL is likely to occur. When lithology is coarse-grained material over fine-grained material, then a sample should be collected just above this interface where NAPL may be pooling above the “aquitarde”. Similarly, where fine-grained material overlies a coarse-grained layer with suspected impacts, the sample should be collected just below the contact. When lithology is fine-grained, then a sample should be collected near the contact with the coarse-grained layer. Alternatively, when lithology is finely bedded (< 1-inch thick), then homogenized samples may be collected over a larger depth interval to gain an “average” observation.

If the sample is being collected from inside a sediment core tube, the tube should be cut open longitudinally along the length of the core tube to prevent additional smearing. Make sure the interior of the sediment is exposed as a “fresh surface”. Be sure to discard any material along the inside side-walls of the core tube; this is called the “smear zone”. The smear zone may mask the true stratigraphy of a subsurface core sample. Then, use a spoon to scrap material across the “fresh” surface of the depth interval of interest, and place into sample jars for further observation. Once the sample volume is collected (approximately 1 oz or more depending upon grain size) the sample is examined and tested as described below.

### **Visual Examination**

In the field, observe sediment core tubes or soil samples for evidence of NAPL. Look at the material and note color and type/nature of occurrence. Observe the exterior and interior sidewalls of the sampling container for signs of staining. If wet, observe the nature of liquid. Among gravels, observe the surface of the gravel for signs of sheen and/or NAPL.

### **Water Sheen Test**

Water sheen screening involves placing soil/sediment in a clear glass jar or a black plastic pan partially filled with water, and observing the water surface for signs of a sheen. The volume of soil/sediment required for observation is approximately one cubic inch, or 10 mls, or about one tablespoon of media. For practical application in the field or lab, place about one cubic inch of soil/sediment (roughly 1 oz) in a 4 to 8 oz jar filled ¼-full with water. For larger volumes, use about 2 oz of material in an 8 oz wide-mouth glass jar filled ¼-full with water. Even larger volumes are needed for gravel. A plastic baggy may be substitute for a glass jar if field conditions require. Crush the material in the jar using a stirring devise (i.e., spoon), and shake the sealed jar vigorously for 30 seconds and allow the material to settle. Observe the water surface and sidewalls of the jar for signs of sheen, LNAPL, and DNAPL. Quantify the amount of sheen and blebs in the water surface using the following sheen classification:

No Sheen	No visible sheen on water surface
Slight Sheen	Light, colorless, dull sheen; spread is irregular, not rapid; sheen dissipates rapidly
Moderate Sheen	Light to heavy sheen, may have some color/iridescence; spread is irregular to flowing, may be rapid; few remaining areas without sheen on water surface
Heavy Sheen	Heavy sheen with color/iridescence; spread is rapid; entire water surface may be covered with sheen; visible droplets of immiscible liquids (i.e. NAPL)

Quantify the spatial coverage of sheen and size/diameter NAPL blebs if observed. The color is often described as rainbow or metallic for sheens and dark brown to black for blebs, droplets, and staining. Observe the sidewalls of the jar and estimate the thickness of LNAPL on the water surface and the thickness of DNAPL accumulated at the bottom of the jar. Record visual signs of staining on jar sidewalls and stirring device.

Field screening results will be recorded on the field logs forms or in a field notebook. Field screening results are site-specific and location-specific. Factors that may affect the performance of this method include: operator experience (experimentation may be required before routine screening is started) ambient air temperature, soil type, soil moisture, organic content, and type of hydrocarbon. Headspace screening may be collected to help correlate results and observations.

## 6.0 Quality Assurance/Quality Control

Not applicable.

## 7.0 Documentation

Documentation may consist of all or part of the following:

- Field sampling forms;
- Field log book; and
- Chain-of-custody forms.

Field records should contain sufficient detail to provide a clear understanding of how and where samples were collected. All documentation shall be placed in the project files and retained following completion of the project.

---

## Field Description Key for Potential NAPL in Sediment

The intent of this field description key is to provide field personnel with guidelines for logging and observing sediment conditions associated with potential presence of Non-Aqueous Phase Liquid (NAPL) in a consistent and factual manner.

### VISUAL DESCRIPTORS

The range of conditions that could exist in sediments include:

- **NAPL** (Non-Aqueous Phase Liquid) – a separate phase liquid that may be lighter than water (LNAPL) or denser than water (DNAPL). NAPL can have varying consistency (viscosity) and can range from non-viscous to highly viscous (taffy-like). NAPL observations should be accompanied by applicable olfactory with smell (see descriptors below) and other visual observations (e.g., color and viscosity). The visual appearance of NAPL should be noted using descriptors below as appropriate. If NAPL is identified, then a sheen or shake test should be completed as described in this SOP in the Hydrocarbon Field Screening by Sheen Test portion.
  - **Free Product** – the entirety of the pore space for a sample interval is saturated with NAPL. Care should be taken to ensure that the saturation described is not related to water in the sample. Depending on the viscosity, NAPL saturated materials may freely drain from a soil sample and should be documented accordingly.
  - **Present**– In some cases, NAPL may be present in the pore spaces, or some of the pore spaces, but not coating the soil grains. The NAPL occurrence may be greater than blebs but not freely draining (saturated) and not hydraulically continuous. In these cases, the appearance/abundance of the NAPL should be noted.
  - **Blebs or Globules**– discrete, multi-shaped NAPL in or on the soil matrix. Include additional descriptors to the extent practicable such as the approximate size (typically ranging in size from 0.01 to 0.05 inches in diameter) and quantity (number of blebs or qualitative estimate) to the extent practical.
  - **Coated** – soil grains are coated with NAPL – there is not sufficient NAPL present to saturate the pore spaces. Use modifiers such as light, moderate or heavy to indicate the degree of coating.
  - **Semi-solid NAPL**– NAPL that is present as a super viscous liquid and appears in a solid or semi-solid phase. The magnitude of the observed solid NAPL should be described (discrete granules, tarry balls, taffy-like, or a solid layer).
- **Sheen** – iridescent sheen. The sheen characteristics need to be described in the field log, including the color, and iridescent sheens need to be distinguished from bacterial sheens which tend to break up at angles on the water surface; whereas a non-bacterial sheen will be continuous and will not break up. Sheens can be described as:
  - Discontinuous sheen (i.e., spotty, streaks, florets) within a section of core and does not fill sediment pore spaces.

- Continuous sheen (i.e., covering an area greater than 1 square inch) within a section of core but does not fill pore spaces. Describe percent cover.
- **Stained** – visible, unnatural discoloration of the soil, with no visible NAPL.

### **Other Visual Impacts and Descriptors**

In many cases, observed NAPL may be associated with a particular stratigraphic layer (e.g, sand lamination, woody debris layer, gravel lense), gas bubble, or void; NAPL distribution in relation to stratigraphy must be described. What does the material look like immediately above and below the area with suspected NAPL (e.g, clay). Impacts should be described using other visual descriptors as well, as applicable. Descriptors may include, but not be limited to, color, consistency, thickness, viscosity, water content, associated stratigraphy, presence shell or wood fragments or other debris, does NAPL flow out of the core tube, does it appear more or less viscous than water, results of jar sheen test, etc. Also note the staining of sampling equipment, and interior and exterior side-walls of the sampling tube, especially if entrainment of NAPL up the side-walls is suspected as an artifact of sample collection.

### **OLFACTORY DESCRIPTORS**

Field personnel will not conduct olfactory testing as part of sample processing, because vapor inhalation is a potential health and safety risk. However, if incidental odors are noted by field personnel during regular sample processing activities, field personnel will record this observation in the field forms. General descriptors that could be used are the following:

- Note odors similar to mothballs, driveway sealer, highway paving oil, sewage or other odors that are acrid, burnt, or sulfur-like, etc.
- Other odors that are not believed to be natural should also be identified with descriptors such as organic, ammonia, sweet, chemical etc., as applicable.
- Use modifiers such as strong, moderate or slight to indicate intensity of the observed odor.
- In instances where multiple odors are present, a combination of descriptors should be used to clearly identify where these co-mingled impacts are present.

However, olfactory descriptions are more subjective than visual inspections. Visual inspection may be aided by a PID, ultraviolet (UV) fluorescence examination, shake test, or similar device, to monitor and record organic odors and suspected NAPL in the field. One may also consider collecting a sample of the suspected NAPL to assess physical characteristics and potential mobility.

## **PID Field Screening (Integral 2004)**

---

Except for sample volumes collected for volatile analytes, sediment from each subsample will be individually mixed in the decontaminated, stainless-steel bowl to a uniform color and texture using a decontaminated, stainless-steel spoon. The sediment will be stirred periodically while individual samples are taken to ensure that the mixture remains homogeneous. Care will be taken to not include sediment that is in direct contact with the aluminum tube. In addition, the cutting of the aluminum tube can introduce metal shavings to the core sediment. Care will also be taken to avoid mixing these shavings into the homogenate. Pre-labeled jars for chemical testing will be filled with the homogenized sediment.

The types and number of field QC samples for subsurface sediment samples will follow the same guidelines prescribed for surface sediment samples. If additional volumes of sediment are required to perform all analyses in addition to QC analyses, an additional core may need to be collected from the same location and subsampled and homogenized accordingly.

Sample handling and storage procedures will follow those described for surface sediment samples in Section 4.6.1 with the following exception. When required, sediment subsamples for volatile organics will be collected from within appropriate intervals following the opening of the core and designation of the lithologic units. This process will minimize the release of volatile organics caused by mixing. Rinsate blanks will be performed at the same frequency (5%) as performed for the surface sediment sampling program.

#### **4.6.4 Subsurface Sediment Sample Field Screening**

In addition to visual observation, headspace screening using a photoionization detector (PID) and/or flame ionization detector (FID) may be used on all sample intervals to aid in the selection of samples to be analyzed.

##### **Headspace Screening**

Headspace screening involves the semi-quantitative measurement of total volatile compounds in the air above the sample material. Headspace concentrations will be measured using the following procedure.

1. A small representative sample will be collected from each sample interval to be screened using a decontaminated sampling spoon. The material will be placed in a resealable plastic bag or glass jar with a septum lid.
2. The bag or jar will be tightly sealed (the jar with aluminum foil and plastic lid with septum opening), and the material will be allowed to warm at least to the ambient temperature ( $>32^{\circ}$  F). The sample will be allowed to sit for at least 10 to no more than 60 minutes to allow headspace concentrations to develop, and shaken

periodically for at least 30 seconds at the beginning and end of the development period.

3. The PID/FID probe tip will be inserted into the container within the headspace, with care taken to avoid taking sediment or moisture into the probe.
4. The highest reading (excluding possible erratic readings) on the meter will be recorded for the sample.
5. The deepest sample interval showing a response during headspace screening will be submitted in the initial round of analyses.

#### **4.7 WASTE DISPOSAL**

---

Any excess water or sediment remaining after processing will be returned to the river in the vicinity of the collection site. Any water or sediment spilled on the deck of the sampling vessel will be washed into the surface waters at the collection site before proceeding to the next station.

All disposable materials used in sample processing, such as paper towels and disposable coveralls and gloves, will be placed in heavyweight garbage bags or other appropriate containers. Disposable supplies will be removed from the site by sampling personnel and placed in a normal refuse container for disposal at a solid waste landfill. Phosphate-free, detergent-bearing, liquid wastes from decontamination of the sampling equipment will be washed overboard or disposed of into the sanitary sewer system. Waste solvent rinses will be held in sealed plastic buckets and disposed of into the sanitary sewer. Oily or other obviously contaminated investigation-derived waste will be placed in appropriate containers, and a waste determination will be made before it is disposed of at an appropriate facility.

#### **4.8 SAMPLE HANDLING AND TRANSPORT**

---

Since samples collected in support of CERCLA activities may be used in litigation, their possession must be traceable from the time of sample collection through laboratory and data analysis to introduction as evidence. To ensure samples are traceable, the following procedures will be followed.

##### **4.8.1 Chain-Of-Custody Procedures**

Samples are in custody if they are in the custodian's view, stored in a secure place with restricted access, or placed in a container secured with custody seals. A chain-of-custody record will be signed by each person who has custody of the samples

# STANDARD OPERATING PROCEDURE

## PID EQUIPMENT CALIBRATION, OPERATION, AND MAINTENANCE

### **Introduction**

The standard operating procedure (SOP) for photoionization detector (PID) equipment calibration describes a procedure to confirm that monitoring equipment used for screening the quality and safety of sediment samples are operating within the manufacturer's specifications.

### **Calibration**

PIDs will be calibrated on a daily basis each morning prior to making measurements and will be adjusted to operate within the manufacturers' specifications. The PIDs will be calibrated using 100 parts per million (ppm) isobutylene calibration gas provided by the equipment vendor.<sup>1</sup> After calibration, the equipment output will read "Span 1 is done and reading is XXX." Manufacturer states that reading should be close to span gas value. Field crew is using a span gas value of 100 ppm  $\pm$  5%. If readings are outside of this value, then equipment will be sent back to the manufacturer for maintenance. All calibration information shall be recorded in the project logbook.

Special attention shall be noted by field crew to instruments that may be affected by the change in the ambient temperature or humidity. Calibration checks should also be performed when sampling conditions change significantly, sample matrix changes, and/or readings are unstable or there is a change of parameter measurements that appear unusual.

As needed through the day, a black marker may be used to confirm a "positive" reading by the PID instrument.

### **Maintenance**

All field monitoring equipment and accessories are to be maintained in accordance with the manufacturer's recommendations and specifications and/or established field practices. All maintenance will be performed by qualified personnel and documented in the field logbook or returned to manufacturer for maintenance.

Equipment requiring battery charging shall be charged as recommended by the manufacturer. Backup batteries for meters requiring them shall be included as part of the meters' accessories. Care must be taken to protect meters from adverse elements. Protective measures may involve placing the meter in a large plastic bag to shield it from the weather.

### **Documentation**

All field equipment calibration, maintenance, and operation information shall be recorded within the field logbook to document that appropriate procedures have been followed and to track the equipment operation.

<sup>1</sup> 100 ppm calibration gas = "Span 1"

Logbook entries shall contain, but are not necessarily limited to, the following:

- Equipment model and serial numbers
- Date and time of calibration or maintenance performed
- Calibration standard used
- Calibration lot number and expiration date if listed on bottle
- Calibration procedure used if there are multiple options
- Calibration and calibration check readings, including units used
- Problems and solutions regarding use, calibration, or maintenance of the equipment
- Other pertinent information

Field records should contain sufficient detail to provide a clear understanding of which equipment was used and how equipment was calibrated. All documentation shall be placed in the project files and retained following completion of the project.

**SOP A-3, SIB Project Area, PHSS  
(Source: Sampling Photography)**

# STANDARD OPERATING PROCEDURE

## CORE PHOTOGRAPHY PROCEDURES FOR SEDIMENT CORING

---

### **Purpose**

The purpose of this standard operating procedure (SOP) is to describe core photography procedures.

### **Scope and Applicability**

This SOP is applicable to taking digital photographs of subsurface sediment cores.

### **Equipment and Materials**

Equipment and materials for taking digital photographs include the following:

- Digital camera
- Spare batteries
- Tripod
- Color calibration card
- Measuring tape
- Light stands
- Digital camera-carrying case and manual
- Photo log form
- Dry-erase board
- Dry-erase marker
- Black waterproof pen

### **Typical Camera Features**

- Save photographs (in standard mode) directly to a memory stick or comparable device
- Auto focus; manual focus available if required
- Zoom
- Brightness control
- Playback of photographs on camera screen
- Display of photograph number, date, and time

- Timed or remote release
- Display showing time remaining on battery and remaining disk capacity
- Ability to protect and delete images that have been taken

## **Camera Use**

A digital camera will be used by the core processing team to photo document the subsurface sediment cores. The field team leader will be responsible for digital photograph documentation or for assigning documentation duties to a team member. Digital photographs will be collected at a high-pixel setting such that enlargements can be made with minimal degradation in picture quality.

## **Photograph Documentation Procedures**

### ***Field Team Responsibilities***

The core processing team will keep a daily hard copy log of all photographs. The following digital photograph data will be collected:

- Date and time—as provided by the camera display
- Team members—list each team member
- Camera identifier (type, model, equipment number)
- Sample Location ID and depth interval
- Photograph ID—record the number of the photograph and the photograph file name (as coded below)
- Description—the target of the photograph

### ***Photography Procedures***

- Sediment cores should be photographed indoors with flood lights and oriented so that shadows are eliminated.
- The camera should be affixed to a tripod and photos taken using a timed or remote release to minimize shaking.
- The axis of the camera lens should be as close to perpendicular as possible to the core to minimize distortion of core and linear features.
- A measuring scale (e.g., tape measure or ruler) should be placed adjacent to the edge of the core as a size reference.
- A color proof strip should be included in the photo to ensure true color reproduction during photo post processing.
- The core Location ID and depth interval should be written onto a dry erase board and included in the photo frame.

### ***Digital Photograph File Name***

At the end of each field day, the member of the field team who is responsible for the camera will transfer the electronic data from the camera to the field operations computer. The folder structure will be as follows (or as specified in the Data Quality Management Plan [DQMP]):

\\DATA\PHOTOS\YYYYMMDD\SAMPLE AREA\file\[1, 2, 3, ....N]

The notation YYYYMMDD represents the year, month, and day. The sample area is the sampling area name (e.g., Willamette River). The individual files for the day (e.g., file 1, file 2, file N) will be placed within this folder using the default file identifier provided by the camera.

### ***Transfer of Information and Archive***

After the photograph disks have been uploaded, the original hard copy of the photograph log will be initialed and dated by the team member who downloaded the photographs, then archived by the field team leader.

### ***Sample Processing Coordinator Responsibilities***

The field team leader will be responsible for 1) reviewing electronic photographs and the logs as they are made available to ensure consistency and completeness of annotations; 2) collecting and archiving the hard copies of the photograph logs; 3) reviewing electronic photographs and the logs as they are made available to ensure consistency and completeness of annotations; and 4) notifying the sampling team leader of apparent inconsistencies and making recommendations for corrective action.

### **Key Checks and Items**

Important checks for digital camera management include the following:

- Make sure the camera's battery is fully charged on a daily basis.
- Keep extra memory sticks available.
- To save battery life, use flash only when necessary.
- Make sure the camera quality level is set at "best" or equivalent (high pixel).
- Review photograph records periodically to ensure that the electronic photographs, dry erase board information, and the Specimen Tally and Location Form agree.
- Leave enough time at the end of the field day to transfer the data.

**SOP A-4, SIB Project Area, PHSS  
(Source: Storm Drain Sampling)**

## 1. PURPOSE AND SCOPE

The following text describes the techniques that will be employed to collect sediment samples at specified locations. For the purposes of this project, and where necessary, HGL will adopt the **SOP for Confined Space Entry to be performed by certified contractors**.

## 2. REQUIRED EQUIPMENT

The following equipment and supplies will be used for sediment sample collection:

- Photoionization detectors (PIDs)
- Laboratory-supplied containers
- Decontamination kit (buckets, brushes, Alconox, and tap and deionized water)
- Camera
- Sharpies/pens
- Labels
- Chain-of-Custody forms
- Ice and cooler
- 25-foot grab sample pole with 12-oz. sample cup
- Paper towels
- Personal protective equipment (PPE), including hard hat, boots, high-visibility vest, safety glasses, and nitrile gloves

## 3. SEDIMENT RETRIEVAL METHODS

The methods for retrieving the accumulated sediment are presented below.

- Using safe lifting techniques, traffic controls (if needed), and implementing all health and safety protocols, open the manhole cover.
- Observe sediment volume present. If the volume is adequate for analytical laboratory requirements (8 oz), proceed with sample collection consistent with this SOP.
- Using a grab sample pole fitted with a sample cup or stainless beaker, collect a representative sample by scooping the sediment from the accumulated location.
- Slowly raise the sample cup to the surface and place the sediment into the laboratory-supplied containers (decant water from top).
- Repeat the procedure until the sample container is filled with sediment.
- Label the sample container.
- Close the manhole cover.
- Decontaminate the sample cup before the next location is sampled.

#### 4. DECONTAMINATION PROCEDURES

Decontamination of sampling equipment must be conducted consistently to ensure the quality of samples collected. Disposable equipment intended for one-time use will not be decontaminated but will be packaged for appropriate disposal.

Decontamination will occur after each use of a piece of equipment between sample locations. All sampling equipment that comes into contact with sampling media (grab pole, stainless beaker, cups, etc.) will be decontaminated according to EPA Region 10 recommended procedures. The following, to be carried out in sequence, is an EPA Region 10 recommended procedure for the decontamination of sampling equipment:

- Non-phosphate detergent and tap water wash, using a brush if necessary
- Tap water rinse
- Deionized/distilled water rinse (first rinse)
- Deionized/distilled water rinse (second rinse)

Equipment will be decontaminated in a predesignated area, and clean bulky equipment items will be stored in their cases or on visqueen in uncontaminated areas. Cleaned small equipment items will be stored in their cases or in plastic bags. Materials to be stored more than a few hours will also be covered.

#### 5. FIELD FORMS

During each site visit to retrieve accumulated sediment, the field crews will complete a field form which will record the following information:

- Name of staff conducting sampling
- Location
- Date/time of sampling
- Presence and approximate depth of any water at the location
- Approximate volume of sediment sampled
- General comments/observations

**Gravity (SOP) A-5, SIB Project Area, PHSS  
(Source: Gravity Marine HVS Sampling)**

## **GRAVITY CONSULTING STANDARD OPERATING PROCEDURE (SOP) A-5**

### **HIGH-VOLUME STORM WATER SAMPLING FOR ANALYSIS OF COMPOUNDS WITH LOW DETECTION LIMITS**

#### **SCOPE AND APPLICATION**

This SOP describes the protocol for collecting high-volume (HV) water samples using a Gravity PR2900 pump system coupled with a polyurethane foam (PUF) cartridge and a vortex separator, the collection of parallel peristaltic whole water sample, and the collection of physical sample parameters. This SOP is specific to HV techniques used for storm water sampling and should be an addendum to the primary projects Quality Assurance Project Plan (QAPP).

High volumes of surface water samples are collected to quantify surface water concentrations of targeted organic chemicals (e.g., dioxins, PCBs, and pesticides) that could be present at levels too low to be detected using conventional sampling methods. This method also allows for quantification of hydrophobic organic chemicals (HOCs) in the suspended particle and dissolved phases of the water column.

HV storm water sampling techniques make it possible to obtain enough mass from the storm event to allow quantitation of the target compounds. In summary, a large volume of water is collected with a pump and passed through a vortex separator and then through a cartridge containing PUF material that binds the dissolved forms of the compound in question. The dissolved compounds that bind to adsorbent foam material (i.e. the PUF) are later extracted in the laboratory and measured on a gas chromatograph/mass spectrometer. Trace metal clean sampling techniques are also used for the collection of HV water samples to be analyzed for organic compounds and conventional parameters, such as total suspended solids, dissolved organic carbon, and total dissolved solids. Using these techniques guarantees a high level of sample integrity and minimizes the potential for contamination during sample handling.

This SOP utilizes and augments the procedures outlined in the San Francisco Estuary Institute's *Field Sampling Manual for the Regional Monitoring Program for Trace Substances* (David et al. 2001), the *Interagency Field Manual for the Collection of Water-Quality Data* (USGS, various dates), and U.S. Environmental Protection Agency (EPA) Method 1669, *Sampling Ambient Water for Trace Metals at EPA Water Quality Criteria Levels* (USEPA 1996). A goal of this SOP is to ensure that the highest quality, most representative data are collected, and that these data are comparable to data collected by different programs that follow EPA guidelines.

## **STATION ACCESS**

Prior to entering select areas for storm water sampling that are safe to access. It may be necessary to acquire permission from the landowner to access the property. Access permission must be acquired in advance of the sampling program and may require a written agreement.

## **STATION LOCATION**

Water samples will be collected at specific HV locations identified in the project planning documents (e.g. Field Sampling Plan [FSP]). Samples will be collected over the period of the storm event so ensure locations have 24/7 access.

## **SUMMARY OF METHOD**

At each station, dedicated/new Teflon™ tubing will be connected to a dedicated decontaminated primary pump attached to a pipe with weighted base mount and flow sensor and lowered into the storm water pipe making sure the primary pump inlet does not come into contact with any accumulated sediment. There will be a dedicated primary pump at each location, the pump is constructed with all stainless steel components and will be decontaminated before deployment. The primary pump variable flow is operated by a surface controller that will be set at approximately 3 L/min and will pump the storm water into a dedicated decontaminated surface level primary glass carboy which will in turn supply both the HVS outflow and whole water sample volume needed for continuous sample flow. Examples of the fully stainless steel primary pumps selected are the Geosub 2 from Geotech and the Proactive Monsoon from ECT Manufacturing. Both of these pumps are designed to continuously pump water to the surface where vertical distances exceed the capabilities of available peristaltic pumps, the pumping rates can also be accurately controlled at the surface using the manufacturer supplied controller units.

Two lengths of dedicated/new Teflon™ tubing will be inserted fully into the primary glass carboy, one of the sampling tubes will be directed to the internal HVS peristaltic pump intake, which leads to a high vortex separator. The high vortex separator is able to separate suspended sediments by forcing the water in a centrifugal fashion before exiting towards the 0.45 micron glass filter and then the PUF cartridge. Water is then drawn through the PUF cartridge which contains solid phase extraction resins that bind dissolved forms of the compounds in question (e.g., HOCs). A constant rate of water, approximately 1.5 L/min, is pumped through this system. Every 15 minutes the rate of water pumped is checked to ensure that water is flowing at a constant rate. To check that the pump is accurately delivering the desired rate of volume, the pump outflow must be checked with a 1 L graduated plastic cylinder and a timer. If the pump is not delivering the correct flow rate, fine adjustments must be made until the optimum flow is achieved.

After the desired volume has passed through the PUF cartridge, the HVS peristaltic pump is turned off and the PUF cartridge and the 0.45 micron glass filter are removed. Two stainless steel nuts that cap each end of the PUF cartridge are reattached. The cartridge is then labeled, taped, placed in resealable bags, and placed in a cooler with wet ice. The volume from the vortex separator containing the suspended particles sample is added to the 0.45 micron flat filter, and placed in a labeled 8 oz jar before being placed in a cooler with ice. The vortex sampler volume is removed by shutting the main line valve to the off position and opening the vortex outlet valve while running the pump for 10 seconds.

Physical field measurements and a separate whole water sample will be collected in tandem with the HVS sampling system by connecting the second Teflon™ tube to a secondary peristaltic pump, tubing set, and secondary glass sample carboy. This pump will also have a flow-thru chamber with YSI Exo multi-meter installed for continuous measurement of Dissolved Oxygen, PH, turbidity, and temperature. Assuming adequate sample volume, flow via the second tubing will be continuous at a similar or lower flow rate than the primary HVS tubing and discharge from the second tubing will alternate between filling the secondary glass carboy and pumping to waste. This set-up intends to keep samples coming out of both tubes representative of the total storm flow throughout the pumping duration, the continuous flow will ensure that the combined HVS and whole water sample collection pumping rates will be equivalent to the primary pump flow rate set to approximately 3 L/min to avoid the primary glass carboy being overfilled during the sample collection period. Once the secondary whole water sample is collected the peristaltic pump will be used to collect TSS and TOC samples from the agitated secondary glass sample carboy in laboratory supplied sample containers for analysis. The remaining whole water sample in the secondary glass sample carboy can be submitted to the laboratory for all other analysis in accordance with project planning documents.

## **PROCEDURES**

The sampling team should comprise two people. Staff are needed to conduct the sampling and keep track of sample logging and sample processing.

### **Equipment Preparation**

A sufficient amount of dedicated sampling equipment will be brought to the field to minimize the amount of decontamination procedures that need to be performed . SGS laboratory is responsible for preparing its equipment prior to delivery. All PUF cartridges will be cleaned, pre-weighed, numbered at the laboratory, and individually packaged before being shipped to the site under chain-of-custody. The list of necessary equipment is provided as Attachment 1 to this SOP.

The following steps are taken to set up the surface water collection system:

1. Assemble and secure the flow meter and primary pump to the weighted base mount.
2. Set up a clean area for the sampling equipment.
3. Attach a length of dedicated/new Teflon™ tubing to the primary pump, which will be secured to the base mounted pipe with flow sensor. The pipe with base mount, primary pump, flow sensor and tubing will then be lowered into the storm water pipe making sure the primary pump inlet does not come into contact with any accumulated sediment. The primary pump intake shall be pointed in the up-pipe direction within the water column. The outflow end of the main sample tube will be directed into the primary glass carboy (Note: The length of the Teflon™ tubing will vary depending on project-specific requirements and storm water manhole vault height at each given station).
4. Insert the intake end of the two lengths of Teflon™ sample tubing into the primary glass carboy.
5. Attach the two lengths of Teflon™ tubing (collecting end) to 30-cm platinum cured silicone™ tubing and a 1-m Teflon™ tubing, sequentially, and then connect the platinum cured silicone™ part of these interconnected pieces of tubing firmly into place inside the large peristaltic pump head. The outlet tubing should be directed away from the storm water conveyance to ensure sampled water does not drain back into the outfall.
6. Secure the pumps and pump speed controllers and connect them to a generator or inverter with an extension cord. The generator should be positioned downwind from the sampling and should not be run while the PUF is being transferred to or from the sampler
7. Connect one of the Teflon™ tubes to a flow thru chamber to the whole water physical sample glass sample carboy and setup YSI Exo1 for water quality monitoring parameter logging.
8. Connect the other Teflon™ tube to the HVS intake tubing.

## **HVS Sample Collection**

The following steps are taken to collect and process a standard HVS storm water sample:

1. Remove the protective cap from the sampling tube and insert fully into the primary glass carboy.
2. Switch the pump on and purge at least 3 tubing volumes of water through the tubing to ensure a representative sample is collected. During purge, calibrate pump flow rate to 1.5 L/min using a 1 L graduated cylinder.

3. Once purging is complete and flow rates are set, attach tubing outlet to vortex separator and pump storm water through the sample tubing into the vortex separator and through the PUF cartridge at a constant rate of approximately 1.5 L/min.
4. Every 15 minutes, record pump rate to ensure that the target rate of approximately 1.5 L/min is maintained. If the pump rate falls +/- 5% outside this range (i.e., outside of the range of 1.425 L/min to 1.575 L/min), adjust the speed of the pump.
5. Turn off the pump once the desired volume of storm water has been pumped through the PUF cartridge or the storm event ends.
6. Remove the PUF cartridge and cap each end with stainless steel nuts.
7. Remove the 0.45 micron flat filter and place in 8 oz. jar. If multiple flat filters are collected during the sample collection pumping these will be combined in the same 8oz jar for compositing at the testing laboratory.
8. Add the solids from the vortex separator into the flat filter 8 oz. jar by shutting the main line valve to the off position and opening the vortex outlet valve while running the pump for 10 seconds to purge the vortex separator. If needed, rinse the inside of the vortex separator with a squirt bottle filled with deionized water.
9. Attach sampling label, which contains the date, time, project name or number, sample ID, type of analysis required, and sampler initials per project planning documents (e.g. Quality Assurance Project Plan [QAPP])
10. Once the PUF cartridge and solids jar are properly closed and labeled, place them inside a cooler containing wet ice and store at approximately 6°C. All samples are to be stored in coolers with ice prior to submittal and/or shipping to the analytical laboratory, per project planning documents (e.g. QAPP)

### **Whole Water Sample Collection**

The following steps are taken to collect the whole water storm water sample, in parallel with the HVS sample:

1. Remove the protective cap from the sampling tube and insert fully into the primary glass carboy.
2. Switch the pump on and purge at least 3 tubing volumes of water through the tubing to ensure a representative sample is collected.
3. Once purging is complete and flow rates are set, attach tubing outlet to the whole water dedicated carboy with an in-line flow-thru chamber connected to a YSI Exo multi-meter installed for measurement of Dissolved Oxygen, PH, turbidity, and temperature set to be recorded every 15 minutes.

4. Every 15 minutes, collect 1L of whole water into the secondary glass carboy. When not actively filling the carboy, this second tubing will be pumping to waste to maintain the constant pumping rate. The outlet tubing should be directed away from the storm water conveyance to ensure sampled water does not drain back into the outfall.
5. Turn off the pumps once the desired volume of storm water has been obtained or the storm event ends.
6. By reversing the peristaltic pump collect the TSS and TOC samples from the agitated secondary glass sample carboy into laboratory supplied sample containers, ensure the samples are properly sealed and labeled, place on wet ice and store at approximately 6°C.
7. Attach sampling label to the remaining whole water secondary glass sample carboy, which contains the date, time, project name or number, sample ID, type of analysis required, and sampler initials per project planning documents (e.g. Quality Assurance Project Plan [QAPP])
8. Once the carboy is properly sealed and labeled, place it on wet ice and store at approximately 6°C. All samples are to be stored on ice prior to submittal and/or shipping to the analytical laboratory, per project planning documents (e.g. QAPP).

## **Decontamination of HV Equipment**

Dedicated sample tubing will be used at each sample location so decontamination will be unnecessary. Prior to sampling, the following steps are taken to decontaminate the HV water sampling equipment. The procedure specific to the high-volume sampling equipment is provided below.

1. Plumb decon silicone and Teflon tubing to the HVS system and whole water peristaltic pump
2. Pump 2 liters of Liquinox solution through PR2900 system
3. Pump 1 liter of DI water through the PR2900 system
4. Pump 1 liter of Methanol through PR2900 system
5. Pump 1 liter of DI water through PR2900 system
6. Pump 0.5 liter of Hexane through PR2900 system
7. Pump 1 liter of DI water through PR2900 system
8. Rinse the dedicated primary pump, primary glass carboy and secondary sample glass carboy with Liquinox
9. Rinse the dedicated primary pump, primary glass carboy and secondary sample glass carboy with DI

10. Rinse the dedicated primary pump, primary glass carboy and secondary sample glass carboy with Methanol
11. Rinse the dedicated primary pump, primary glass carboy and secondary sample glass carboy with DI
12. Rinse the dedicated primary pump, primary glass carboy and secondary sample glass carboy with Hexane
13. Rinse the dedicated primary pump, primary glass carboy and secondary sample glass carboy with DI
14. Cap all exposed inlets and outlets and wrap the primary pump with aluminum foil ready for sample collection

## **WATER QUALITY MEASUREMENTS**

Physical and chemical water parameters will be collected at storm water stations. Several physical and chemical water parameters are best measured in the field because of the unstable nature of the parameter or because the information is needed to direct further sampling. It is frequently preferable to perform these analyses in the field, especially if the samples will not be immediately transported to the analytical laboratory (pH, in particular, should be measured in the field if feasible). A YSI multimeter Exo1 with flow thru chamber will be used to log Dissolved Oxygen, pH, turbidity, and temperature parameters.

The YSI will run for the full duration of the sampling event to observe any potential changes in the physical parameters of the sample. The physical parameter data will be recorded every 15 minutes during sample pumping at each location.

Documentation of instrument information will adhere to project planning documents (e.g. FSP), and at a minimum will contain the name(s) of the person(s) making the measurement and the field equipment used to make that measurement must be recorded in the field logbook and on any field forms used during the sampling event. Equipment maintenance and calibration records must be kept in logbooks and field records so that the procedures are traceable. All field records will be checked by field staff for completeness and electronically provided to the Client.

## **STORMWATER FLOW MEASUREMENT**

A Greyline Stingray 2.0 flow sensor (or equivalent) will also be incorporated into the sampling program to measure flow and volume. The flow sensor transmits ultrasonic pulses that travel through the water and reflect off the liquid surface. To monitor water level, the Stingray 2.0 precisely measures the time it takes for echoes to return to the sensor. Velocity is measured with an ultrasonic signal continuously injected into the flow. This high frequency sound is

reflected back to the sensor from particles or bubbles suspended in the liquid. If the fluid is in motion, the echoes return at an altered frequency proportionate to flow velocity. The Stingray 2.0 uses this Doppler frequency shift to accurately calculate flow velocity. The Stingray will be attached to the base plate of the pole used to deploy the sampling tube.

The Stingray will run for the full duration of the sampling event to observe any potential changes in the flow. The flow sensor Greyline Logger software will display and record near continuous log files and flow rates in graph and table formats. Flow data reports including minimum, maximum and average flow, and calculated flow totals will be generated.

## **SAMPLE HANDLING**

Standard “clean and dirty hand” techniques will be observed on this project. Clean hands are required for sample collection and handling, as described above. Field staff will wear appropriate non-contaminating, disposable, powderless nitrile gloves during the entire sampling operation. Gloves will be changed frequently, usually with each change in task (wearing multiple layers of gloves allows rapid glove changes).

*Clean hands* are required for all operations that involve equipment that comes into contact with the sample, including the following activities:

- Handling the PUF column, 0.45 micron flat filter and vortex separator vial
- Handling the intake end of the sample tube or line
- Setting up working space inside the processing chambers
- Setting up the equipment (i.e., high volume sampler and PUF cartridges) inside the chambers
- Handling the vortex separator
- Changing the chamber covers as needed.

*Dirty Hands* take care of all operations that involve contact with potential sources of contamination, including the following activities:

- Working exclusively exterior to the processing and preservation chambers
- Preparing a clean workspace (inside boat)
- Preparing and operating the sampling equipment, including the pumps and discrete samplers
- Handling the generator or other power supply for samplers
- Handling the tools, such as hammers, wrenches, keys, locks, and sample-flow manifolds
- Handling the single or multi-parameter instruments for field measurements

- Setting up and checking the field-measurement instruments
- Measuring and recording the water depths and field measurements.

All samples are stored in coolers with ice at approximately 6°C until transferred to the laboratory at the conclusion of the sampling day or the following day. The sampling team leader is responsible for maintaining sample integrity throughout the sampling event.

Sample contamination will be avoided by handling the sample containers with clean gloves, and transferring the samples into clean refrigerators (or clean coolers) immediately after samples have been brought back from the field. Sample bottles will always be handled by personnel wearing disposable, powderless nitrile gloves. This includes any and all sample handling that may occur during sample packing and shipping.

## ATTACHMENT 1. FIELD EQUIPMENT LIST

- High volume peristaltic pump with vortex separator
- Primary in-line pump
- Secondary peristaltic pump
- teflon® tubing
- Primary glass carboy
- Secondary glass sample carboy
- YSI Exo1 water parameter multi-meter capable of measuring pH, reduction/oxidation (redox) potential, temperature, specific conductance, turbidity, and dissolved oxygen
- Greyline Stingray 2.0 flow sensor or equivalent
- Teflon-lined polyethylene sample tubing (length is site dependent)
- Platinum cured silicone tubing
- Plastic zip-ties
- Water Sampling Log forms
- Sample tags/labels and appropriate documentation (e.g., chain-of-custody forms)
- Insulated cooler(s), chain-of-custody seals, Ziploc® bags
- Sample containers (PUF cartridges, vortex separator vials)
- Coolers
- Wet ice
- Nitrile gloves
- First aid kit
- Eye wash kit
- Duct tape
- Clear tape
- Packing tape dispenser
- Tool box
- Coated weights for water samplers
- Non-metallic wire for winch spool
- 2000 watt power generator or inverter
- Paper towels
- Dilute solution of Liquinox
- Deionized water
- Extension cord
- Power strip
- Resealable plastic bags (i.e., 1 gallon and 1 quart)
- Methanol
- Hexane
- 0.45 micron flat filters

**SOP A-6, SIB Project Area, PHSS  
(Source: In-Line Sediment Trap)**

## 1. PURPOSE AND SCOPE

The following text describes the techniques that will be employed to collect in-line sediments at locations identified in the Pre-Design Investigation (PDI) Work Plan.

## 2. EQUIPMENT

To assess incoming contaminant loads and movement of settleable suspended solids, in-line sediment traps will be deployed and sampled. In-line sediment traps will be installed and retrieved in select locations as described in the PDI Work Plan.

In-line sediment traps addressed by this SOP include the deployment of four 1-Liter HDPE sample bottles held in place with a custom stainless-steel bracket. At each designated sampling location, in-line sediment traps will be installed at the bottom of the conveyance system. In-line sediment traps will be firmly secured to the conveyance system to prevent unintended transport of the equipment. All in-line sediment traps and related equipment will be decontaminated prior to installation.

The HGL Confined Space Entry SOP will be followed by certified contractors entering manholes.

## 3. DEPLOYMENT OF SEDIMENT TRAPS

As identified in the PDI Work Plan, in-line sediment trap structures will be installed (Figure 1). Field crews **with confined space entry training** will perform a confined space entry in accordance with HGL Confined Space Entry SOP to install the sediment traps in the flow. A confined space entry will also be required to collect the sediment samples. Each of the 1-liter HDPE sample bottles with removeable Teflon®-lined lids will be held to the bottom of the pipe using custom stainless-steel hardware and brackets (Figure 2).

Sediment traps will be deployed at each location and the sample bottles will be retrieved at the intervals described in the PDI WP. When sample bottles are collected and archived, a clean bottle will be installed in the trap. Sediment samples will be capped, labeled, sealed, and submitted to the laboratory in accordance with the appropriate project planning documents. In general, procedures detailed in this SOP are adopted from the approved Portland Harbor RI/FS Stormwater Field Sampling Plan (LWG 2007; Appendix C).

Figure 1. Schematic of deployed Boston sediment trap.

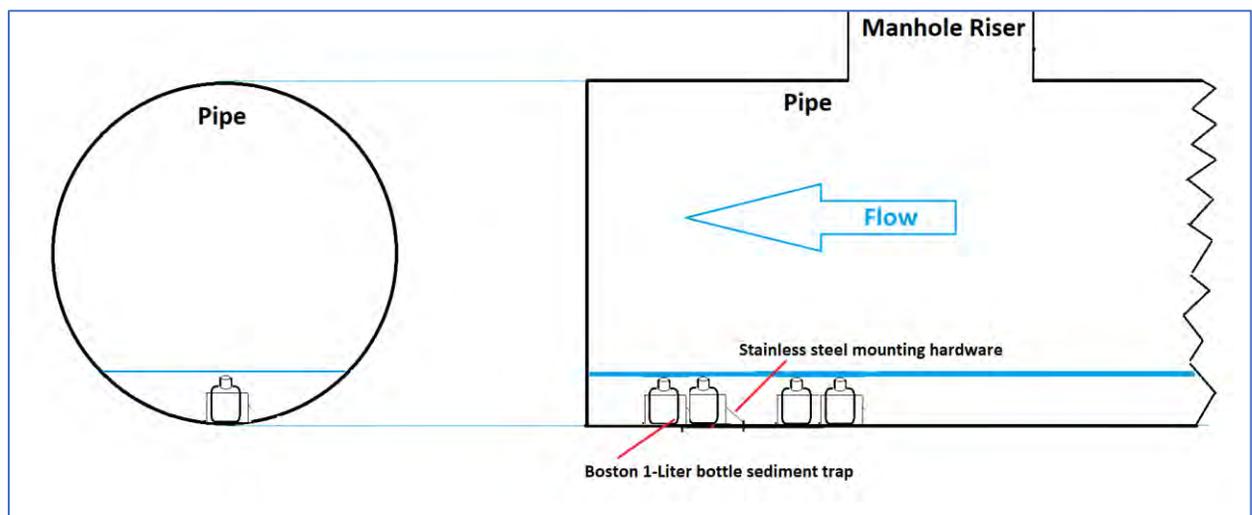

Figure 2. Installation photograph of example deployed sediment traps.

#### 4. INSTALLATION METHODS

Experienced field personnel will install the in-line sediment traps using stainless steel hardware and using inert materials. A confined space entry will be required to install the in-line sediment traps. Where traffic controls are required, a traffic control permit will be obtained from the City of Portland. An encroachment permit from the City may also be required to install the in-line sediment traps.

When installing the brackets in the field at the sampling sites, field crews will clean the area around the stainless-steel anchor bolts to remove any concrete dust or debris. After the bolts are set or other procedures are complete, the work site will be scrubbed with a brush to remove any debris and rinsed with deionized water before the sampling hardware (sample bottle holder) is mounted. Care will be taken to capture the rinse water from the work area.

#### 5. LIST OF EQUIPMENT NEEDED FOR IN-LINE SEDIMENT TRAP SAMPLING

The following equipment and supplies will be used for sediment sample collection:

- Photoionization detectors (PIDs)
- Confined space entry and personnel retrieval equipment
- Laboratory-supplied 1-Liter sample bottles
- Decontamination kit (buckets, brushes, Alconox, and tap and deionized water)
- Camera
- Sharpies/pens
- Labels
- Chain-of-Custody forms
- Ice and cooler
- Paper towels
- Personal protective equipment (PPE), including hard hat, boots, safety glasses, high-visibility vest, nitrile gloves, and ear plugs for drilling activities
- Confined space entry PPE.

## 6. SEDIMENT RETRIEVAL METHODS

In accordance with the PDI WP, the sediment traps will be collected and archived in the analytical laboratory and a clean bottle will be installed to the trap bracket. The methods for retrieving the accumulated sediment are presented below. A confined space entry will be performed to retrieve sediment samples according to these instructions:

- Using safe lifting techniques, traffic controls (if needed), and implementing all health and safety protocols, open the manhole cover.
- Perform the confined space entry into the manhole and prepare to retrieve the sediment trap bottles.
- Implement **“clean hands – dirty hands” method** (EPA 1996; Attachment B) for collecting samples.
- Use phthalate-free vinyl gloves to place the Teflon lids on the sample bottles.
- Remove the sample bottle from the bracket and transfer each bottle to the surface.
- Label the bottle, pack on ice, and prepare for transport to the analytical laboratory.
- Place new laboratory-provided 1-Liter sample bottles back into the brackets, remove the lids, and store the lids in a phthalate-free bag.
- Exit the confined space and replace the manhole cover.

## 7. DECONTAMINATION PROCEDURES

Decontamination of sampling equipment must be conducted consistently to ensure the quality of samples collected. Disposable equipment intended for one-time use will not be decontaminated but will be packaged for appropriate disposal.

Decontamination will occur prior to each use of a piece of equipment. All sampling devices that potentially contact sampling media (grab pole, stainless beaker, cups, etc.) will be decontaminated according to EPA Region 10 recommended procedures. The following, to be carried out in sequence, is an EPA Region 10 recommended procedure for the decontamination of sampling equipment:

- Non-phosphate detergent and tap water wash, using a brush if necessary
- Tap water rinse
- Deionized/distilled water rinse (first rinse)
- Deionized/distilled water rinse (second rinse)

Equipment will be decontaminated in a predesignated area, and clean bulky equipment items will be stored in their cases or on visqueen in uncontaminated areas. Cleaned small equipment items will be stored in their cases or in plastic bags. Materials to be stored more than a few hours will also be covered.

## 8. FIELD FORMS

During each site visit to retrieve accumulated sediment, the field crews will complete a field form which will record the following information:

- Name of staff conducting downloading
- Location
- Date/time of sampling
- Approximate volume of sediment sampled
- Condition of the sediment traps
- General comments/observations

**SOP A-7, SIB Project Area, PHSS**  
**(Source: Horizontal and Vertical Control)**

# STANDARD OPERATING PROCEDURE

## HORIZONTAL AND VERTICAL SURVEY

### CONTROL

---

#### **Introduction**

This Standard Operating Procedure (SOP) has been developed for the Pre-Remedial Design Sampling and Baseline Investigations (PDI) at the Portland Harbor Superfund Site located in Portland, Oregon to confirm accurate positioning of vessels and samples during sample collection activities. The survey control requirements described in this SOP are specifically for environmental sample collection and will generally comply with map-grade precision and accuracy in contrast to the geodetic-grade precision and accuracy performed for the Bathymetric Survey conducted by David Evans and Associates (DEA). However, the same survey control points and geodetic parameters will be used in both surveys for consistency, and a portion of the quality assurance/quality control (QA/QC) process will involve consultation with DEA Oregon Professional Land Surveyor (PLS) staff to review the map-grade data collected for the environmental sample collection.

The organization of this SOP is as follows:

- Methodology Overview
- Project Geodetic Parameters
- Survey Accuracy, Precision, and Control
- Primary Equipment
- Hand-Held GPS Operation
- Vessel Navigation and Equipment Operation
- Data Processing and QA/QC Procedures

Tables, figures, and attachments are presented at the end of the SOP.

#### **Methodology Overview**

##### ***Horizontal (Map) Data Collection***

A combination of vessel-mounted and hand-held GPS receivers will be used to navigate to sampling locations and to collect map location coordinates (Northings, Eastings) for those sampling locations. The vessel-mounted GPS receivers will be the primary tool used for navigation to the pre-planned sampling locations in a GIS file, which will be pre-loaded into the vessel navigational system. The hand-held GPS devices will be used as a backup and confirmation of vessel position only if there are problems with the vessel GPS navigation system or if there is no specific vessel navigation system (i.e., smaller boats). Since the inception of field work, the vessel GPS coordinates have been consistently verified and deemed to be sufficient to meet position and accuracy requirements for the project. The hand-held GPS devices will primarily be used for studies involving small vessels. These devices will also have the pre-loaded basemap content depicting planned sampling locations.

The vessel GPS will operate in two modes, collecting both a separate continuous data stream of positional information (line file) and recording GPS soundings (target file) when a sample is specifically

collected. The sample location target file will be recorded when the sampling device is in position for the grab (e.g., when sampler is on the river bottom). The specific Location ID associated with the sample will also be recorded in the GPS device log. Field personnel will be required to write that same Location ID on their field data collection forms at the same time. Both the continuous and episodic dataset will be timestamped to allow comparison of the two types of data. This data will be recorded and maintained on the vessel, and will also be exported from the vessel navigation system and archived to project servers on a daily basis.

The hand-held GPS devices will be operated independently of the vessel's systems and will be used to record a location sounding wherever a sample is collected only for studies unable to use the vessel GPS navigation system. The sample location sounding will be recorded approximately at the same time as when the vessel GPS measurement is collected (e.g., when sampler is in position). The specific Location ID associated with the sample will also be recorded on the GPS device. Field personnel will write this Location ID on the field forms only if the vessel measurement described earlier cannot be collected for some reason (e.g., equipment failure). These measurements will also be timestamped. The data from the hand-held GPS devices will be wirelessly synchronized to a "cloud" web service in near real-time; the data from the "cloud" will also be downloaded and saved to project servers daily.

### ***Vertical Data Collection***

Vertical (elevation) data is also required for water levels, sample collection depth below surface water, and bottom (mudline) depth location for some types of sample locations. For increased precision and accuracy, it is proposed that bottom (mudline) depth locations (e.g., for sediment cores) be calculated from the bathymetric surface to be developed by the hydrographic survey performed by DEA (since the data will be collected within a few months of each other). The NAVD88 elevation will be calculated from the intersection of the surface map location coordinates collected as described earlier, projected vertically down to the bathymetric surface (United States Army Corps of Engineers [USACE], 2004). The elevation from the intersection of the bathymetric surface will be used as the final or "best" elevation for the sample.

In contrast, for depth measurements that require less precision (e.g., water levels, depth to samples below water surface), the onboard vessel sonar will be used to record depth and then subsequently calculate elevation. All depths will be recorded relative to the water surface and time tagged to correct with time tagged gauge data for obtaining riverbed elevations. The elevation will be calculated to NAVD88 datum. To correct elevations, gauge data from the Northwest River Forecast Center will be downloaded for gauge PRT03, which is representative of the former Morrison gauge which has been moved. This gauge does not report NAVD88 elevations but rather reports a value that is 0.3 feet above Columbia River Datum (CRD). Corrections from CRD to NAVD88 differ moving down the river from the gauge due to the fact that NAVD88 is a reference normal to gravity (water does not flow if the elevation is unchanging), and CRD is a gradient datum that follows the lower water surface. In Portland Harbor, the difference between CRD and NAVD88 (Geoid12b) ranges from 0.00 feet CRD = -5.16 feet NAVD88 (Geoid12b) at Willamette River river mile (RM) 2.0, to 0.00 feet CRD = -5.41 feet NAVD88 (Geoid12b) at Willamette River RM 12.8 (approximate location of PRT03 Gauge). Accordingly, a correction to the Willamette Gauge in Portland would be  $-5.41+0.3$  or  $-5.11$  feet at RM 12.8. An approximation would be to subtract 5 feet from the gauge reading for the full length of the

study area, but precision will vary depending on tides and river gradient.

For sample locations requiring vertical information, depth will be recorded by field staff on their data collection forms relative to the water surface, and these values will be loaded to the project database as described in the Data Quality Management Plan (DQMP). Final calculated NAVD88 elevation data (feet) will also be entered into a separate data field in the project database after completion of spatial analysis, calculations, and QA/QC. DEA will provide support during the QA/QC process to verify proper calculation of NAVD88 elevation data.

### ***Location Position Recording in Project Database***

#### Discrete Samples

When discrete samples are collected, the Location ID and the location coordinates (Northing/Easting) will be recorded on the GPS device(s) and the field data collection form(s). The location coordinates will be based on the vessel GPS instantaneous target measurement. This target measurement will be the location coordinate pair loaded initially to the project database. After the field event is completed, the target measurement will be compared to the line file (vessel continuous GPS measurement) to confirm that the coordinate pair loaded to the project database is appropriate. If analysis reveals precision or accuracy issues, the loaded location coordinate pair in the project database may be updated and edited with a better value derived from the line file. In general, the hand-held GPS devices will be used as a backup and confirmation of vessel position only if there are problems with the vessel GPS navigation system or an independent navigation system is not available on the vessel. These coordinates will be loaded to the project database only if there is a significant problem with the vessel GPS (e.g., equipment failure) or if there is no vessel GPS.

#### Composite Samples

When composite samples are collected, location coordinates will also be recorded as both target measurements and continuous measurements using the vessel GPS. The continuous GPS measurements will be recorded during the entire compositing event, and instantaneous target measurements will be collected when the sampler is in position for each individual composite grab. At each compositing location, a target measurement will be recorded in the vessel GPS along with the Location ID with an “a,” “b,” or “c” suffix. These measurements will be recorded on the field forms in the same manner (e.g., there will be three sets of location coordinates, lithologic descriptions, etc.).

When the location data is loaded to the project database, a single set of location coordinates will be recorded in the project database with a Location ID that excludes the “a,” “b,” or “c” suffix. As a presumed middle time point, the “b” set of coordinates will be loaded with the primary Location ID to the project database. After the field event is completed, the target measurement associated with the “b” location composite will be compared to the line file (vessel continuous GPS measurement) to assess vessel position and the timeframe of the entire sampling event to confirm if the coordinate pair loaded to the project database is appropriate. The goal will be to finalize the location coordinate information in the project database based on the most representative position based on this analysis. Similar to discrete sample collection, a hand-held GPS device and related data will only be loaded to the project database if there is a significant problem with operation of the vessel GPS or if the vessel does not have a GPS.

Finally, after field data are collected and surveys are completed, as defined in the DQMP, the location coordinate data will be joined with the tabular data collected by the field teams and loaded to the project database.

## **Project Geodetic Parameters**

The geodetic parameters to be used for the PDI field studies will be as follows:

***Horizontal Datum:*** North American Datum of 1983 (2011)

***Projection:*** State Plane Coordinate System (SPCS) Oregon North Zone

***Vertical Datum:*** North American Vertical Datum of 1988 (NAVD88) Geoid12b

***Units:*** International Feet

## **Survey Accuracy, Precision, and Control**

The anticipated horizontal accuracy of environmental sampling associated with vessel and hand-held GPS devices is a range of 1 to 5 meters (target 1 to 2 meters for the DGPS unit itself). This should be consistent with RI target accuracy (Integral 2002) and best practices (Puget Sound Estuary Protocols [PSEP] 1998 and US Environmental Protection Agency [EPA] 2008).

The anticipated vertical accuracy of final elevation calculations derived from vessel sonar systems is anticipated to be 1.0 meter.

Table 1 summarizes the survey control locations used in the DEA Bathymetric Survey, which will be used for the environment sample collection work described in this SOP. Figure 1 shows the PH2 piling at Fred Devine boat dock, and Figure 2 shows the approximate locations of the survey control references. Attachment 1 contains detailed survey sheets of the control points: Raindeer, PH1 and PH2, and 2100.

## **Primary Equipment**

- Trimble® SPS 461 GPS with dual antennas (vessel GPS)
- A-frame assembly, sampling winch (vessel boom)
- Trimble® R1 (hand held GPS), tethered to Bluetooth® capable smartphone or tablet, ESRI Collector software with Trimble® GNSS Status middleware
- GPS owner's manual
- Writing tools (pencils, Sharpie®)
- Field logbook
- Spare batteries and/or battery charger
- Compass
- Tape measure

## **Hand-Held GPS Operations**

For ease of use, the project team will utilize smartphones tethered to the Trimble® R1 GNSS Receiver via a Bluetooth® connection. The smartphone will be configured with Trimble's middleware software called GNSS Status to convert and stream NMEA satellite data to the smartphone for real-time

correction and display to a simple electronic data collection form developed on the ESRI Collector platform. The form will contain a limited number of data fields, including location, study name and operator, date, and notes or comments. This form is not intended to duplicate the content and scope of the field data collection forms, but rather clearly link the GPS data to those forms via the unique Location ID. There are metadata fields available as well from these GPS records, such as estimated horizontal accuracy.

Collected data recorded onto the phone will be transmitted wirelessly via a synchronization process invoked when data is “saved” to the device. The data will be pushed to AECOM Online’s Portal and ArcGIS Server for storage of “corrected” location coordinates, Location ID, and other information captured when the GPS sounding is recorded. The sampling event will be trackable in near-real-time as samples are collected on the ArcGIS Portal Interface. Either dedicated, experienced GPS-operators will be collecting the measurements on the smartphones, or, due to the very simple nature of the interface, field personnel will be trained to use the devices. Initial training sessions were already successfully conducted March 19-20, 2018 on use of the smartphone GPS interface. These handheld devices were successfully used for the first 2 weeks of field work. For some studies, such as the smallmouth bass tracking study, these handhelds may be used as the primary GPS due to smaller vessel configuration.

### **Vessel Navigation and Equipment Operation**

Vessel positioning will be conducted through the marine navigation and hydrographic software package HYPACK. This software package allows the visualization of the vessel over navigable charts, the processing of satellite corrections, stored hardware, and vessel parameters, as well as the storing of physical target locations during sampling activities. HYPACK version 2017 will be used for this project.

Vessel position is measured using a Trimble SPS 461 GPS dual antenna receiver. The dual antennas provide precise vessel positioning via both satellite and differential radio corrections along with heading correction to 0.09 degree. GPS data is output through a serial connection into computer running the HYPACK software, for vessel positioning and target collection.

At each sampling location, depth to mudline will be measured using an onboard fathometer (with lead line as confirmation as needed) immediately prior to or during the sampling. Water depths are measured at each station using an Airmar ss510 survey sonar at the sampling point and confirmed daily with a lead line with reference to water surface. Vertical measurements will be recorded to the nearest 0.1 foot. Water depths will be converted to elevations in NAVD88 based on the river stage at the time of sampling as recorded at the closest available tide gage.

### **Data Processing and QA/QC Procedures**

All GPS devices will be subject to a position check to confirm the accuracy of the on-vessel GPS and hand-held GPS devices and to validate the positions derived from each GPS receiver. Correctors being applied as needed, resulting in a position that is within specified positioning accuracy of the DEA published position for control monument PH1 and PH2. At the start and end of each field day, the PH2 benchmark location will be visited by boat to perform a position check. At the piling serving as the control monument, the on-vessel GPS calibrated to the top of A-frame assembly will be maneuvered as close to the benchmark piling as possible to record a point. The GPS-derived position

of the sampling vessel is compared with the known horizontal location; results will be recorded in HYPACK to confirm that accuracy is within +/- 2 meters. For handheld GPS, field staff will occupy the PH1 at the Swan Island boat launch parking lot. Using the R1 and phone/tablet combination GPS setup, the field staff will hold the R1 above PH1 and wait for a satellite “fix,” and when ready, the staff will record the GPS location in Collector. This GPS location will be compared to the known coordinates to confirm the accuracy is within +/- 2 meters. The survey control monuments act as a known location to allow for corrected station location coordinates during post-processing of data as needed. If a need arises to locate another benchmark, there are several USGS control points near the project area and near the AECOM project warehouse. Experienced GPS operators on the project team will be involved in all aspects of field data collection events to troubleshoot devices and assist in daily review of extracted geospatial datasets. Additional details on QA/QC procedures can be found on the DQMP.

## GNSS Setup on RAINDEER

**SOP A-8, SIB Project Area, PHSS  
(Source: Trident Probe)**

# **TRIDENT PROBE STANDARD OPERATING PROCEDURES**

## **TECHNOLOGY DESCRIPTION**

The Trident probe is a direct-push, integrated temperature sensor, conductivity sensor, grain-size sensor and porewater sampler developed to screen sites for areas where groundwater may be discharging to a surface water body (Chadwick et al., 2003; Figure 1). Differences in observed conductivity and temperature indicate areas where groundwater discharge is occurring. The integral porewater sampler can be used to rapidly confirm the presence of groundwater constituents and map the subsurface distribution of contaminants of concern.

### **Trident Conductivity/Temperature Sensors**

The subsurface temperature sensor consists of a ruggedized digital oceanographic thermometer embedded near the tip of a 90 cm long stainless-steel probe (Figure 1). The sensor has a measurement range of -5 to +45 °C at an accuracy of <0.1 °C, and a resolution of 0.001 °C. The sensor response time is about 60 s. The subsurface conductivity probe utilizes a small diameter, stainless steel, AC-excitation 3-electrode sensor, installed at the tip of the same 90 cm probe that houses the temperature sensor (Figure 1). The conductivity sensor has a range of 0 to 80 mS/cm, an accuracy of <2% of the calibrated range, and a resolution of 0.01 mS/cm. The subsurface probe is used to measure the bulk conductivity signal which varies primarily as a function of changes in salinity, and secondarily as a function of clay content and porosity. A reference conductivity and temperature sensor also is mounted on the instrument frame to provide a direct comparison of the overlying surface water conditions with the interstitial water conditions (Figure 1). For the temperature sensor, areas of groundwater seepage may appear either as warm or cold contrast to the surface water depending on the seasonal and site characteristics. For the conductivity sensor, areas of likely groundwater seepage are generally associated with low conductivity in coastal areas where fresh groundwater is discharging to seawater, but may be associated with high conductivity in rivers and lakes

where the groundwater often has higher total dissolved solids relative to the surface water.

### **Liquid-Tip Conductivity Sensor**

The subsurface conductivity probe can also be used in the “liquid tip” configuration in which the sensor is housed within a secondary screen and responds only to the porewater conductivity (Chadwick et al., 2007; Figure 2). The liquid tip configuration uses a small diameter sampling tube to purge the conductivity cell until the readings stabilize (generally <100 ml; Figure 3). The data are then recorded in the same manner as with the bulk conductivity sensor.

### **Data Acquisition System**

Trident sensors are coupled through an underwater connector and cable to a deck unit that integrates the probe and reference temperature, conductivity and SED-FSP signals with the signal from a Global Positioning System (GPS) sensor mounted on the top of the push-pole (Figure 1). The GPS is a Garmin model 17 with a stated accuracy of <15 m in standard mode, and <3 m in Wide-Area Augmentation System (WAAS) mode. The integrated data stream from the deck unit is sent to a laptop via RS-232. The laptop is used to apply calibration and temperature corrections to the signals, and record and display the results.

### **Porewater Sampler**

The water-sampling probe allows interstitial waters to be extracted from the sediment at selected depths up to about 90 cm below the sediment water interface. Porewater is collected by a low-flow peristaltic pump extraction through a small-diameter, Teflon-coated, stainless steel probe (Figure 4). The probes consist of a length of 9.5 mm diameter stainless steel tubing fitted with a solid, removable point. On the side of the tube near the tip there is a sample port consisting of a hole covered by a small mesh size (250  $\mu\text{m}$ ) stainless steel screen. The screen section is easily removable for cleaning or replacement if required (Figure 4). The porewater sampler can also be configured with a secondary screen with a sand-pack to provide a pre-filter for the sampling and to minimize clogging of the sampler (Figure 5). This secondary screen is installed over the

outside of the probe, and the void between the probe and the screen is packed with pre-cleaned sand. Multiple probes can be used together to further increase surface area, enhance sampling rate, and minimize potential clogging.

## **FIELD SAMPLING PROCEDURE**

A Trident survey is conducted by inserting the probe into the seabed (seabed is used here to mean the bottom of the ocean, estuary, or bay) from a boat or by wading. In operation, the Trident probe can be deployed in several ways depending primarily on the depth of the site. In water of moderate depths (1-10 m), the probe is easily deployed from a small boat using the push rod (Figure 6). It is important that the boat be well anchored to minimize lateral loading on the probe during the insertion. In deeper water (>10 m), the probe can be deployed by diver, or can be attached to a landing frame (Figure 6). In very shallow water (<1 m) the probe can be installed by wading.

### **Conductivity and Temperature Sampling**

Once on station with the probe inserted, data is collected from the conductivity and temperature sensors using the TridentTalk software. If the liquid tip sensor is being used, the cell must be purged prior to data collection. The TridentTalk software provides a display of the probe and reference temperature and conductivity signals, along with the GPS position. The software also automatically calculates and displays the probe vs. reference temperature and conductivity contrast. Once the sensor readings have stabilized, the data is recorded by activating the “Log current data” button on the TridentTalk display. The data can then be reviewed in numeric format, or displayed spatially using the AGIS graphical information system software. The spatial AGIS display provides a capability for rapidly evaluating the most likely areas of groundwater discharge based on temperature and conductivity contrast. Once data recording is completed, the probe is retrieved. If the liquid tip sensor is being used, the sensor cell must be cleaned between stations by removing any accumulated particles and rinsing the cell with appropriate solution (generally surface water). A typical shoreline sampling grid for a Trident sensor survey is shown in Figure 7. Typical results for a liquid-tip sensor survey are shown in Figure 8.

## **Porewater Sampling**

Once on station with the porewater probe inserted, the probe and sampling tube is purged of ~3 volumes using the sampling pump. The pump should be run at a low enough rate to avoid over pressure and clogging or excessive vacuum bubbles in the sampling line. With the sampler purged, the porewater samples can then be collected in accordance with the volume and quality control requirements of the project. Once the sampling is complete, the probe is retrieve and decontaminated in accordance with project requirements prior to sample collection at the next station. Typical results for a shoreline porewater sampling survey are shown in Figure 9.

## **ADDENDUM 1. DETAILED FIELD PROCEDURES FOR TRIDENT PROBE SENSOR SAMPLING**

Standard field procedures for Trident sensor sampling are described below. While these procedures are generally applicable, they serve as a guide and may be subject to site-specific variations depending on the particular study design and requirements.

### **Applicable Field Conditions**

Trident sensor measurements are applicable to a wide range of field conditions. In general, the measurements focus on characterizing subsurface and surface water temperature and conductivity, and the contrast between these, at soft-bottom sediment sites with the potential for groundwater-surface water interaction. Using various configurations, the sensors have been extended to use in gravel, cobble, and other more resistant bottom types, but these typically require special armoring and drive systems. The temperature sensors are applicable over the widest range of conditions. The conductivity sensors can be used in either the “bulk” conductivity configuration, or the “liquid-tip” configuration.

In the bulk configuration, the conductivity sensor is exposed directly to the sediment, and the reading reflects the combined conductivity of the sediment and the porewater. Bulk measurements can be useful in certain applications, particularly when evaluating relative subsurface difference either in sediment properties (when the porewater conductivity is relatively constant), or when evaluating porewater conductivity differences (when the sediment properties are relatively constant). In general, these measurements will not be useful for measuring contrast with surface water because of the bias associated with the effect of the sediment on the reading. Also, it is often the case that the degree of uniformity of the porewater conductivity or sediment characteristics is not known or is known to be variable and then the bulk measurements may be difficult to interpret. The bulk conductivity probe should thus only be used with these factors in consideration.

In the liquid-tip configuration, the conductivity sensor is contained within a screened tip on the probe which allows porewater to be drawn in. Thus the liquid-tip configuration gives readings that reflect only the porewater conductivity. This allows for more direct

assessment of potential groundwater discharge zones and for direct comparison with surface water readings to evaluate contrast. The liquid-tip configuration utilizes a 250 micron outer screen over the sensor. Thus it tends to work well in medium to coarse grain sediments. In very fine sediments, particles can be drawn into the sampler and this may confound the measurement because of the effects of the particles on the conductivity reading. Thus caution should be used in applying this configuration in fine sediments. Evidence of high particle loads entering the measurement cell is usually apparent when the probe is retrieved and disassembled for cleaning between stations. If significant amounts of fine particles are found in the cell, and if the readings appear erratic or biased relative to expected values, consideration should be given to using the Trident porewater sampler with a sand pack to collect small volume water samples for conductivity measurements using the handheld Ultrameter instead of the in situ sensor.

### **Probe Configurations**

The Trident provides for a range of different probe configurations. Sensor probes can be combined with water sampling probes. Multiple probes can be used for replication or at different sampling depths. Surface water sensors and samplers can be included. Probe configuration is largely a function of the study design so there is no standard configuration. The maximum number of probes for the hex-head Trident is 6 not including surface water probes. The maximum probe length is typically 3 feet, although longer probes have been applied for special studies. Using the extension plates, each probe can be set to an independent subsurface penetration depth. In general, when using the sensor probes to detect groundwater upwelling zones, the strength of the signal tends to increase with depth. Thus setting the probes to deeper depths will generally result in stronger signals. Setting probes at depths less than about 6 inches can result in higher potential for draw-down, so shallow probe depths should be used with caution.

### **Sensor System Preparation**

Preparation of the sensor system prior to field measurements is described below.

1. Gather the equipment and materials described in the equipment list.

2. Clean the sensor probes with warm water and a lab-grade detergent such as Alconox or RBS, using a green scrunge pad to polish the conductivity sensors thoroughly.
3. For the liquid-tip probe, assemble the sensor probe inside the probe armor and the liquid-tip screen.
4. Connect the probe(s) to the Trident deck unit and verify communications.
5. Run TridentTalk, select the probe settings option, note down all of the previous calibration coefficients, and then change all of the coefficients to a slope of one (+1.000) and an intercept of zero (+0.000).
6. Calibrate the temperature sensor(s) using a three-point calibration in a temperature bath (verified by NIST thermometer) spanning the range of expected values at the site, and three replicate measurements for each standard.
7. Input the calibration data into the standard calibration spreadsheet template and note the new calibration coefficients.
8. Enter the new coefficients into TridentTalk for the respective probes.
9. Using the temperature bath (verified by NIST thermometer) check the calibrated temperature readings against the thermometer. Relative percent differences (RPDs) should be in the range of 0.1-0.5%.
10. Calibrate the conductivity sensor(s) using a three-point calibration of NIST standards spanning the range of expected values at the site, and three replicate measurements for each standard. If the liquid-tip configuration is being used, calibrate with the probe armor and screen in place.
11. Input the calibration data into the standard calibration spreadsheet template and note the new calibration coefficients. Relative standard deviations (RSDs) of the replicates should be in the range of 0.1-1%.
12. Enter the new coefficients into TridentTalk for the respective probes.
13. Using the conductivity standards check the calibrated readings against the standards. Relative percent differences (RPDs) should be in the range of 0.1-1%.
14. Rinse the probes with clean DI water to remove any residual calibration solution, and zip tie a clean plastic bag over the tip to keep clean until ready for field use.

15. Assemble the probes onto the hex-head (and extension plates if needed) in the desired configuration.
16. Install the stopper plate including the stopper plate pole and adjustment rod.
17. Insert the shore extension pole into the hex-head with a retainer pin.
18. Connect the sensor cables and zip tie them to the short pole to provide strain relief. If desired, install the camera system on the frame for use in verifying the push depth.
19. Connect the communication cables to the deck unit and the deck unit to the field computer, start TridentTalk, and verify that all of the probes and the GPS unit are functioning properly. If installed, verify the camera is functioning properly.
20. If using the liquid-tip, connect a clean length of tubing of sufficient length to reach the bottom at the deepest target station, and secure it to the short pole using zipties. The tube and cables can be bundled with zipties as well.
21. The system is now ready for field use.

### **Field Sensor Measurements**

Follow the procedure below to collect Trident sensor measurements in the field.

1. Assemble all of the required equipment from the equipment list, along with the assembled Trident system on the sampling boat or at the shoreline area if wading.
2. Connect the probes and the GPS to the deck unit, and the deck unit to the field laptop, start TridentTalk, and verify that everything is functioning properly.
3. In TridentTalk, setup the station name and data file as needed. Normally the station name is change for each station, and the filename is change for each day. Replicates at the same station are automatically designated under TridentTalk.
4. Setup the desired sampling interval in seconds.
5. Verify that the computer clock is properly set and synchronized in TridentTalk.
6. If using the liquid-tip, connect the purge tube to the pump.
7. Using the boat or wading, position to the target station. This can be done using the GPS, a navigation system, or by known landmarks.
8. Use a depth meter or other method to determine and record the water depth in the logbook. Assemble the required number of push poles to reach the bottom.

9. Lower the probe to the bottom, adding poles as needed to reach the target depth. If the push poles are to be released after the push, make sure an install the release pin in the first pole.
10. Gage the initial contact with the bottom by feel and note the pole height relative to the water level or the boat rail. Push the probe into the bottom until significant resistance is felt. Note the pole height and estimate if the probe is fully penetrated. If not, continue to work the probe in by hand or using a slide hammer or other drive method until full penetration is achieved. If installed, verify penetration with the camera. If using the release point, pull the release pin and remove the push poles. Note the bottom type in the logbook based on feel or visual observations in shallow water.
11. If using the liquid-tip, start the cell purge and purge a minimum of 100 ml, checking the stability of the temperature and conductivity readings during the purge using TridentTalk.
12. Install the Trident GPS in the top of the push pole. If using the release point, hold the GPS over the push location. If using a handheld GPS, hold it next to the push pole or above the push location and record the position.
13. Once the readings have stabilized, record the data for the station and note the values and the position data in the logbook.
14. Retrieve the probe to the surface using the push poles or retrieval line as applicable.
15. Clean the probe to remove any sediment or residue using a soft brush and DI water. If using the liquid-tip, remove the screen, check for excessive particles in the cell, and clean the screen, sensor and probe body. If an significant contamination or residue is present (e.g. sheen), use a mild lab detergent to clean the probe and rinse with DI water.
16. If the liquid-tip is used, flush the tubing with surface water, and then pump any residual water out of the tubes. If significant contamination or residue is present the tubing can be deconed by pumping a mild lab detergent followed by DI water through the system, or the tubing can be changed out for new tubing.

17. Once the probe and the tubing are clean, re-assemble any screens, tips or tubing that was removed/disconnected, and the probe is ready for redeployment.
18. Once a day (generally at the end of the day), the conductivity sensor calibration should be checked by immersing the sensor in a NIST standard. Normally the standard should be the one that is closest to the range of conductivities observed at the site. If the RPD of the reading is more than 2% different from the standard, the sensor should be lightly polished with a scrunge pad and the check repeated. If the reading is still more than 2% different from the standard, the sensor should be re-calibrated in accordance with steps described above in the System Preparation section.
19. The temperature sensor calibrations are generally very stable and should not require re-calibration during the period of a typical survey.

## **ADDENDUM 2. DETAILED FIELD PROCEDURES FOR TRIDENT PROBE WATER SAMPLING**

Standard field procedures for Trident water sampling are described below. While these procedures are generally applicable, they serve as a guide and may be subject to site-specific variations depending on the particular study design and requirements.

### **Applicable Field Conditions**

Trident water sampling is applicable to a wide range of field conditions. In general, the sampling focuses on collection of sufficient subsurface and surface water samples volume to characterize the target water quality and chemical conditions for the study. Using various configurations, the water samplers have been extended to use in conditions ranging from fine sediments to gravel, cobble, and other more resistant bottom types. There are two primary configurations for the water sampler including the un-armored small-diameter probe with small screen, and the armored large diameter probe with large screen and internal sand-pack filter. Sampling in coarse sediment can often be carried out using an un-armored probe with just the small filter screen. Sampling in fine sediments often requires the use of the armored probe with the larger outer screen and internal sand-pack filter.

### **Probe Configurations**

The Trident provides for a range of different probe configurations. Water sampling probes can be combined with sensor probes. Multiple probes can be used for replication or at different sampling depths. Surface water sensors and samplers can be included. Probe configuration is largely a function of the study design so there is no standard configuration. The maximum number of probes for the hex-head Trident is 6 not including surface water probes. The maximum probe length is typically 3 feet, although longer probes have been applied for special studies. Using the extension plates, each probe can be set to an independent subsurface penetration depth. Setting probes at depths less than about 6 inches can result in higher potential for draw-down, so shallow probe depths should be used with caution.

## Water Sampling System Preparation

Preparation of the water sampling system prior to field measurements is described below.

1. Gather the equipment and materials described in the equipment list.
2. Clean the water sampling probes, screens and tips with warm water and a lab-grade detergent such as Alconox or RBS, using a soft bristle brush. Rinse thoroughly with DI water and allow to dry. Place the screens and tips in clean Ziploc bags. Note that the solutions used to decontaminate the probes may vary depending on if the probe is being used only to collect water quality samples, or if the probe is being used to collect samples for chemical analysis.
3. Replace the internal tubing in the probe with new, pre-cleaned Teflon tubing. Install a pre-cleaned Teflon tee or union fitting on the exposed end of the tubing and cover the open end with a blank ferrule fitting or parafilm.
4. If using the sand-pack and probe armor, assemble the water sampling probe inside the probe armor. Ziptie a plastic bag over the clean probe tip.
5. Assemble the probes onto the hex-head (and extension plates if needed) in the desired configuration.
6. Install the stopper plate including the stopper plate pole and adjustment rod.
7. Insert the shore extension pole into the hex-head with a retainer pin.
8. Connect a pre-cleaned length of tubing to the probe coupling of sufficient length to reach the bottom at the deepest target station, and secure it to the short pole using zipties. A surface water sampling tube can also be ziptied to the pole or the frame at the desired height above the bottom. If multiple tubes are being used they can be bundled with zipties as well.
9. If not using the sand-pack, install the small screen and tip and re-cover the tip with the protective bag.
10. If using the sand-pack, stand the probe vertically with the probe tips pointing up and install the small inner and large outer screens. Fill the void between the inner probe and the outer screen with a slurry of filter sand by rinsing it into the void with clean DI water. Leave about 1/8 inch unfilled for the tip to fit into. Install the

large tip and re-cover the probe tip with the plastic bag. Note that different filter sands can be used for different applications.

11. The system is now ready for field use.

### **Field Water Sampling**

Follow the procedure below to collect Trident sensor measurements in the field.

1. Assemble all of the required equipment from the equipment list, along with the assembled Trident system on the sampling boat or at the shoreline area if wading.
2. Using the boat or wading, position to the target station. This can be done using the GPS, a navigation system, or by known landmarks.
3. Use a depth meter or other method to determine and record the water depth in the logbook. Assemble the required number of push poles to reach the bottom.
4. Lower the probe to the bottom, adding poles as needed to reach the target depth. If the push poles are to be released after the push, make sure to install the release pin in the first pole.
5. Gage the initial contact with the bottom by feel and note the pole height relative to the water level or the boat rail. Push the probe into the bottom until significant resistance is felt. Note the pole height and estimate if the probe is fully penetrated. If not, continue to work the probe in by hand or using a slide hammer or other drive method until full penetration is achieved. If installed, verify penetration with the camera. If using the release point, pull the release pin and remove the push poles. Note the bottom type in the logbook based on feel or visual observations in shallow water.
6. Start the sample purge and purge a minimum of 100 ml, checking the stability of the water quality readings during the purge using the handheld Ultrameter.
7. Hold the GPS next to the push pole or above the push location and record the position.
8. Once the water quality readings have stabilized, record the data for the station and note the values and the position data in the logbook.
9. If chemical samples are to be collected, continue to pump and collect samples as required.

10. Retrieve the probe to the surface using the push poles or retrieval line as applicable.
11. Clean the exterior of the probe to remove any sediment or residue using a soft brush and Alconox solution. If using the sand-pack, remove the tip and the outer screen and dispose of the sand. Remove the internal screen and clean the entire probe exterior, screens and tip with Alconox solution and a soft brush followed by DI rinse.
12. If the sample tubing is to be re-used, decon the tubing by back flushing with the sampling pump using Alconox solution followed by DI water (or other decon solutions as required by the chemical sampling). Alternatively, the short length of internal probe tubing can be deconed in this way, and the long length of sampling tubing can be replaced with new pre-cleaned tubing. It is not advised to change the internal probe tubing in the field, but this can be done as well if the application requires. Rinse the probe tips again with DI after the back flush is completed.
13. Once the probe and the tubing are clean, re-assemble any screens, tips or tubing that was removed/disconnected. If the sand-pack is being used, re-pack the probe with clean sand. The probe is ready for re-deployment.

## **ADDENDUM 3. TRIDENT EQUIPMENT LIST**

### **General Hardware**

- Standard Hex Head and Hardware
- Extension Plate Hex Head and Hardware
- Extension Plates and Hardware
- Stopper Plate with Seal Glands
- Stopper Plate Pole and Adjustment Rod
- Single Probe Hex Head (for single probe configurations only)
- Single Probe Extension Plates and Hardware (for single probe configurations only)
- Single Probe Stopper Plate (for single probe configurations only)
- Short (1 m) Push Pole
- Standard Push Poles (2 m) and Clips
- Probe Mounting Brackets

### **Sensor System**

- C/T Sensor Probes
- C/T Reference Probes
- C/T Small Tips
- C/T Armor
- C/T Liquid-Tip Screens
- C/T Large Tips

### **Water Sampling System**

- PW Probes
- PW Small Screen and Tips
- PW Armor
- PW Large Screens and Tips
- Pump – Masterflex E/S Portable Sampler IP54

- Pump Head – Masterflex L/S #7518-10
- Pump Tubing – Masterflex silicone L/S 14
- Sample Tubing – Cole Parmer 1/8” Teflon FEP
- Couplings - Entegris Teflon PFA 1/8”SU2N, UT2N

### **Deck Gear and Ancillary Equipment**

- C/T and GPS Cables - Impulse
- Trident Deck Unit
- Trident Integrated GPS – Garmin GPS16
- Handheld GPS – Trimble GeoXT
- Field Computers – Dell Inspiron
- Inverter – Black and Decker 1008 48-OC
- Battery – Duralast Marine Battery
- USB/Serial – Keyspan USA 19-HS
- GFI – TRD Model 14650 Software – Trident Talk, Rosepoint Coastal Explorer
- Water Quality Meter – Myron L Ultrameter model 6P
- Hand-Held Depth Sounder – Vexilar LPS-1

### **Expendables**

- Wipes – Kimwipes
- Gloves – Cole Parmer Powder free nitrile EW-81602-65
- Wrap - Parafilm
- Cleaner - Alconox
- Lab-Water – 18 Mohm lab-grade deionized water
- Distilled water
- Filter Sand – Sigma-Aldrich Davisil 636, Polysciences Glass Beads (250-300µm), #60 Industrial Silica Sand (and others)

# Standard Operating Procedure Geotechnical Soil Logging

---

<b>Prepared by:</b>	Lilian Lorincz, Morteza Khorshidi	<b>Date:</b>	08/19/2021
<b>Checked by:</b>	Frank Greguras	<b>Revision Number:</b>	4
<b>Approved by:</b>	Eric Johnson	<b>Approval Date:</b>	08/20/2021

---

## 1 Purpose

This Standard Operating Procedure (SOP) defines standard practices for identification and classification of soil samples collected during geotechnical site investigations and preparation of the associated field logs. This document is based on applicable ASTM International (ASTM) standards, Federal Highway Administration (FHWA) guidance documents, and the 2010 California Department of Transportation (Caltrans) Soil and Rock Logging, Classification, and Presentation Manual.

## 2 Scope

This SOP does not supersede or replace the ASTM standards that it is based on. The intent of the SOP is to clearly communicate the procedures for logging, describing, and identifying soil samples in the field based on visual manual procedures. The field soil descriptions developed based on the procedures described herein may be corrected, calibrated, or verified based on the results of the geotechnical laboratory tests performed following the subsurface investigation

## 3 General Requirements

All work should be performed in accordance with the project specific geotechnical site investigation plan as well as the project specific health and safety plan. While not covered specifically in this SOP, at a minimum the field engineer performing the soil logging should have a thorough understanding of the following prior to the commencement of the subsurface investigation:

- Field exploration methods, sampling requirements, and types and frequency of field tests to be performed
- The site-specific health and safety plan and any associated site hazards
- Permitting requirements and restrictions (borehole destruction, encroachment, etc.)
- Traffic control requirements and plan
- Underground Service Alert (USA) ticket and member utility response status

Boreholes should be logged by a suitably trained engineer or geologist, under the supervision of the project design geotechnical engineer or engineering geologist.

## 4 Field Procedure for Soil Logging

### 4.1 General Project and Borehole Information

Field logs should properly identify the general project information, site location, drilling tools and methods used, and the personnel involved in the fieldwork. The information described in Table 1 should be recorded for each borehole. A sample field logging form for a sample project is provided in Appendix A.

**Table 1. Required Field Logging Form Information**

	Description
1	Date of Work
2	Borehole Identification
3	Project and Site Information <ul style="list-style-type: none"> <li>• Project name</li> <li>• Project number</li> </ul>
4	Borehole Location and Elevation <ul style="list-style-type: none"> <li>• Latitude and longitude or northing and easting</li> <li>• Horizontal coordinate system and datum</li> <li>• Elevation</li> <li>• Vertical datum</li> <li>• Method of borehole location and approximate accuracy</li> </ul>
5	Personnel <ul style="list-style-type: none"> <li>• Logger (engineer or geologist)</li> <li>• Drill crew</li> <li>• Inspector (or other visitors)</li> </ul>
6	Drilling and Sampling Equipment <ul style="list-style-type: none"> <li>• Drill rig (manufacturer and model, and equipment identification number)</li> <li>• Drilling method</li> <li>• Drill tooling               <ul style="list-style-type: none"> <li>– Drill rod description (type, diameter)</li> <li>– Drill bit description</li> <li>– Casing (type, diameter) and installation depth</li> </ul> </li> <li>• SPT hammer type</li> <li>• Hammer Energy Ratio (ERi)</li> <li>• Type of Sampler(s) and Size(s)</li> </ul>
7	Groundwater <ul style="list-style-type: none"> <li>• Method of observation</li> <li>• Date, time, and elevation of each reading</li> </ul>

Adapted from Figure 2-3 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

Boreholes will be drilled using a combination of hand auger, hollow stem and solid stem continuous flight augers, and/or rotary wash methods. At the near surface, hand augering is preferred to obtain shallow subsurface information, confirm the borehole location is absent of underground utilities, and collect bulk samples. Below hand auger depths, hollow stem or solid stem continuous flight augers should be utilized until groundwater is encountered and measured. Hollow stem drilling should be performed in accordance with ASTM D6151 and solid stem drilling with ASTM D1452.

Sampling should be performed using split-barrel samplers and thin-walled (Shelby) samplers in dry drilling. The split-barrel (or split spoon) sampler is used to obtain driven disturbed soil samples. The two most common types of split-barrel samplers include the Standard Penetration Test (SPT) sampler and the Modified California sampler. The SPT sampler is best suited to obtain disturbed samples in cohesionless soils performed in accordance with ASTM D1586. The Modified California sampler is used when gravels are present or for soil samples that need to be confined in a liner. The Modified California sampler should be used in accordance with ASTM D3550. The type of hammer and hammer efficiency should be requested from the drilling contractor to provide accurate correction factors for the standard penetration resistance, referred to as the number of blow counts or “N”, when the split-sampler is driven. The thin-wall tube (Shelby) sampler is hydraulically advanced to obtain relatively undisturbed samples of cohesive soils.

After groundwater is encountered, the drill rig equipment should be converted to rotary wash drilling and performed in accordance with ASTM D5783. Rotary wash methods are preferred below the groundwater table to reduce borehole caving, heaving, and the disturbance of samples. In addition to split-barrel and Shelby tube sampling, the Dames & Moore Piston sampler and Pitcher Barrel sampler can be used to collect soil samples below the groundwater table. The Dames & Moore Piston sampler is hydraulically advanced and useful for sampling soft soils where sample recovery is often difficult and in soils that will require laboratory testing. The Piston sampler is used in accordance with ASTM 6519-15. The Pitcher Barrel sampler is used to obtain relatively undisturbed samples in hard fine-grained soils and granular soils with clay. The Pitcher Barrel is used in accordance with ASTM D1587.

While sampling, field tests including the pocket penetrometer test and hand-held torvane test should be performed on cohesive samples that are free of substantial voids or hard inclusions to ensure an accurate representation of consistency. Both tests should only be used as an index of the unconfined compressive strength (UCS) of cohesive samples and should not be used in place of a laboratory strength tests. Pocket penetrometer tests should be performed in accordance with the recommendations provided by the device manufacturer and hand-held torvane tests should be performed in accordance with ASTM D4648. Other tests for plasticity, dry strength, dilatancy, and toughness should be performed on cohesive samples to identify and describe the soil in accordance with ASTM D2488.

## 4.2 Soil Description

This section presents the method for soil identification and description based on ASTM D2488, USBR (2001), and Caltrans Soil and Rock Logging, Classification, and Presentation Manual (2010). A degree of uncertainty exists in visual soil description and identification such as for identifying percentages of soil constituents and for the other soil descriptions explained in the subsequent sections. Laboratory testing should be performed on selected soil samples to confirm field identifications.

### 4.2.1 Soil Description and Identification

When describing and identifying soil, record the data on the field log in accordance with, and in the sequence shown in Table 2. Items marked “required” must be used, when applicable, to describe the soil sample. For

example, percent cobbles and/or boulders is required only if cobbles and/or boulders are encountered. Do not report negative information (e.g. no boulders or cobbles).

Use semicolons between required descriptors, commas within a descriptive component for optional descriptors, and a period at the end of each descriptive sequence. Table 2 below summarizes the order of appearance for description terms in the borehole log. The items marked with a dot under the required column must be used to describe the soil sample.

**Table 2. Identification and Description Sequence**

Sequence	Identification Components	Required	Optional
1	Group Name	●	
2	Group Symbol	●	
3	Consistency of Cohesive Soil	●	
4	Apparent Density of Cohesionless Soil	●

Figure 2-5 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.2 Group Name and Group Symbol

The group name and group symbol for a soil should be identified using Table 3 and Table 4 for fine or coarse-grained soils, respectively. This should be performed in accordance with ASTM D2488 and is only applicable to materials passing the 3-inch sieve. The percentage(s) of cobbles and/or boulders (if encountered) must be reported on the borehole log per Section 4.2.3.13.

A soil is classified as fine-grained if it contains 50% or more material that passes through a Number 200 sieve, measured by weight. A coarse-grained soil contains fewer than 50% fines. A coarse-

grained soil is identified as gravel if the percentage of gravel is greater than the percentage of sand, or as sand if the percentage of gravel is equal to or less than the percentage of sand. A well-graded sand or gravel has roughly equal amounts of all particle sizes. A poorly-graded sand or gravel is missing one or more particle sizes.

If a soil falls into two groups, a borderline symbol should be used. To indicate that the soil may fall into one of two groups, use a borderline symbol, which is two symbols separated by a slash, e.g., SC/CL or CL/CH. A borderline symbol must be used when:

- The percentage of fines is estimated to be between 45 and 55%. One symbol must be for a coarse-grained soil with fines; the other for a fine-grained soil, e.g., GM/ML or CL/SC
- The percentage of sand and the percentage of gravel are estimated to be about the same, e.g., GP/SP, SC/GC, GM/SM
- The soil could be well or poorly-graded, e.g., GW/GP, SW/SP
- The dominant fine-grained component of the soil could be either silt or clay, e.g., CL/ML, CH/MH, SC/SM

The group name for a soil with a borderline symbol must be the group name for the first symbol, except for:

- CL/CH lean to fat CLAY
- ML/CL CLAYEY SILT
- CL/ML SILTY CLAY

Borderline symbols should not be used indiscriminately. Use of a single group symbol is preferred. For soils that contain about 10% fines, a dual symbol consisting of two symbols that are separated by a hyphen may be used. Dual symbols include GP-GM, SW-SC, and CL-ML.

**Table 3. Identification of Fine-Grained Soil**

Group Symbol	Coarse Fraction	Coarse Fraction	Sand or Gravel	Group Name	
CL	<30% plus No.200	<15% plus No.200		Lean CLAY	
		15-25% plus No.200	% sand $\geq$ % gravel	Lean CLAY with SAND	
	$\geq$ 30% plus No.200	15-25% plus No.200	% sand < % gravel	< 15% gravel	Lean CLAY with GRAVEL
			% sand $\geq$ % gravel	$\geq$ 15% gravel	SANDY lean CLAY
			% sand < % gravel	< 15% sand	SANDY lean CLAY with GRAVEL
			% sand < % gravel	$\geq$ 15% sand	GRAVELLY lean CLAY
ML	<30% plus No.200	<15% plus No.200		SILT	
		15-25% plus No.200	% sand $\geq$ % gravel	SILT with SAND

Figure 2-8 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

### 4.2.3 Consistency of Cohesive Soil

The required field procedure for the determination of consistency of cohesive soil is to perform tests with a pocket penetrometer or torvane on relatively undisturbed samples, or to perform down-hole vane shear tests. The test result(s) are added to the description sequence using the syntax “PP = measurement”, “TV = measurement”, or “VS = measurement” where the measurement is in units of tons per square foot or tsf. Based upon the field test measurement, the consistency will range from very soft to hard (AASHTO 1988). The pocket penetrometer and other instrument tests provide an index of the unconfined compressive strength values (UCS) that can be correlated to the undrained shear strength value (Su) of the soil, but laboratory strength testing should be performed to validate field measurements.

For pocket penetrometer and torvane tests, the testing surface of the soil sample should be cleaned with a soil knife prior to performing the field test to remove any obvious signs of disturbance due to sample handling. Performing multiple pocket penetrometer tests and averaging the sum is recommended to ensure the consistency value is representative of the entire sample. Avoid performing field tests on an area that has visible hard fragments such as wood or gravel. Use the terms and criteria in Table 5 to describe the consistency of predominantly cohesive soil.

**Table 5. Consistency of Cohesive Soil**

Description	Pocket Penetrometer Measurement, PP,(tsf)	Torvane Measurement, TV,(tsf)	Vane Shear Measurement, VS,(tsf)
Very Soft	PP < 0.25	TV < 0.12	VS < 0.12
Soft	0.25 ≤ PP < 0.5	0.12 ≤ TV < 0.25	0.12 ≤ VS < 0.25
Medium Stiff	0.5 ≤ PP < 1	0.25 ≤ TV < 0.5	0.25 ≤ VS < 0.5
Stiff	1 ≤ PP < 2	0.5 ≤ TV < 1	0.5 ≤ VS < 1
Very Stiff	2 ≤ PP < 4	1 ≤ TV < 2	1 ≤ VS < 2
Hard	4 ≤ PP	2 ≤ TV	2 ≤ VS

Figure 2-9 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.3.1 Apparent Density of Cohesionless Soil

The apparent density of predominantly cohesionless soil ranges from very loose to very dense and is described in accordance with ASTM D1586. Table 6 presents the density terms for cohesionless soils. The apparent density can be obtained from the N-value recorded during a Standard Penetration Test, that is then corrected for energy efficiency. An energy efficiency of 60% is considered standard per ASTM D4633.

**Table 6. Apparent Density of Cohesionless Soil**

Description	SPT $N_{60}$ (blows/ft)
Very Loose	$N_{60} < 5$
Loose	$5 \leq N_{60} < 10$
Medium Dense	$10 \leq N_{60} < 30$
Dense	$30 \leq N_{60} < 50$
Very dense	$50 \leq N_{60}$

Figure 2-10 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

The  $N_{60}$  value is defined as

$$N_{60} = N_{measured} * (ER_i/60)$$

The hammer energy ratio is known as the hammer efficiency and is obtained from the drilling contractor. This value can be assumed as 60% if the value is unknown at the time of drilling. After drilling, the value should be requested and the density descriptions should be checked and updated, if necessary.

$$ER_i = \text{Hammer energy ratio (\%)}$$

#### 4.2.3.2 Color

The predominant color(s) of the soil sample should be described during logging based on the Munsell Soil Color Charts (2009) and in accordance with ASTM D1535. The terms presented in Table 7 can be used if significant color variation is observed.

**Table 7. Color Terms**

Description	Definition	Examples
Variegated	Having streaks, marks, or patches of a different color or colors; varicolored	Variegated green, gray and black
Mottled	Having spots or blotches different colors	Mottled green, gray and black
Multicolored	Lots of colors (state predominant colors)	Multicolored, green, gray and black

Figure 2-11 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.3.3 Moisture

The moisture of the soil should be evaluated after obtaining the soil sample, and prior to packaging, so that the in-situ state is described. Table 8 presents the moisture conditions.

**Table 8. Moisture**

Description	Criteria
Dry	No discernable moisture
Moist	Moisture present, but no free water
Wet	Visible free water

Figure 2-12 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.3.4 Percent or Proportion of Soil

The percentage or proportion of gravel, sand, and fines in a soil should be evaluated by weight of the total sample (excluding the cobbles and boulders), either by using a proportional descriptor (seen in Table 9) or as a weight percentage (not using a range), that is estimated to the nearest 5% of the total sample. The soil should be described for each soil particle size identified in order of decreasing proportion. The percentages should be written on a borehole log in order of decreasing composition.

**Table 9. Percent of Proportion of Soil**

Description	Criteria
Trace	Particles are present but estimated to be less than 5%
Few	$5 \leq Pp \leq 10\%$
Little	$15 \leq Pp \leq 25\%$
Some	$30 \leq Pp \leq 45\%$
Mostly	$50 \leq Pp \leq 100\%$

Figure 2-13 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.3.5 Particle Size

The particle sizes in a sample are described in Table 10. Typically, sand and gravel particles are readily identified due to their size; however, particles smaller than a silt are not easily discernible by visual examination.

**Table 10. Particle Size**

Description	Sieve Size	Approximate Particle Size (in)
Boulder	Greater than 12 in.	$12 < P_s$
Cobble	3 to 12 in.	$3 < P_s \leq 12$
Coarse Gravel	3/4 to 3 in.	$3/4 < P_s \leq 3$
Fine Gravel	No. 4 to 3/4 in.	$1/5 < P_s \leq 3/4$
Coarse Sand	No. 10 to No. 4	$1/16 < P_s \leq 1/5$
Medium Sand	No. 40 to No. 10	$1/64 < P_s \leq 1/16$
Fine Sand	No. 200 to No. 40	$1/300 < P_s \leq 1/64$
Silt and Clay	Passing No. 200	$P_s \leq 1/300$

Figure 2-14 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

To determine the range of particle sizes present in a sample, a sedimentation test can be performed. This is a field test that uses a small sample of the soil that is placed into a clean, clear vial and filled with water. The vial is sealed, shaken with the water, and placed down so that the particles can settle. For particles larger than a silt, it takes about ½ minute to drop a distance of 100 mm. This test offers a rough estimation of size and the proportion of particles in a sample.

#### 4.2.3.6 Particle Angularity

For coarse-grained soils, the angularity of particles can be described in accordance with Table 11. A range of particle sizes may be present for the same type of particle (i.e., “subangular to subrounded gravel”) and should be noted on the borehole log in order of increasing roundness.

**Table 11. Particle Angularity**

Description	Criteria
Angular	Particles have sharp edges and relatively plane sides with unpolished surfaces
Subangular	Particles are similar to angular description, but have rounded edges
Subrounded	Particles have nearly plane sides, but have well-rounded corners and edges
Rounded	Particles have smoothly curved sides and no edges

Figure 2-15 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.3.7 Particle Shape

The shape of the gravels, cobbles, and boulders can be described as flat, elongated, or a combination of both. Table 12 presents the description terms for particle shape.

**Table 12. Particle Shape**

Description	Criteria
Flat	Particles with width/thickness > 3
Elongated	Particles with length/width > 3
Flat and Elongated	Particles meet criteria for both flat and elongated

Figure 2-16 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.3.8 Plasticity

The plasticity of a fine-grained soil is measured in the field by the ability to roll the sample into a 1/8-inch-thick thread based on the criteria presented in Table 13. Plasticity ranges from nonplastic to high plasticity for fine-grained soils.

**Table 13. Plasticity**

Description	Criteria
Nonplastic	A 1/8-in. thread cannot be rolled at any water content.
Low	The thread can barely be rolled and the lump cannot be formed when drier than the plastic limit.
Medium	The thread is easy to roll and not much time is required to reach the plastic limit. The thread cannot be rerolled after reaching the plastic limit. The lump crumbles when drier than the plastic limit.
High	It takes considerable time rolling and kneading to reach the plastic limit. The thread can be rerolled several times after reaching the plastic limit. The lump can be formed without crumbling when drier than the plastic limit.

Figure 2-17 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.3.9 Dry Strength

The dry strength is applicable for fine-grained soils and described using Table 14. The dry strength test is performed by allowing a portion of the sample to dry out and then pressed between the fingers. The dry fragments that cannot be crumbled or broken tend to exhibit high dry strength and plasticity. Fragments that can be crushed with gentle finger pressure are characteristic of low dry strength and plasticity.

**Table 14. Dry Strength**

Description	Criteria
None	The dry specimen crumbles into powder with mere pressure of handling.
Low	The dry specimen crumbles into powder with some finger pressure.
Medium	The dry specimen breaks into pieces or crumbles with considerable finger pressure.
High	The dry specimen cannot be broken with finger pressure. Specimen will break into pieces between thumb and a hard surface.
Very High	The dry specimen cannot be broken between the thumb and a hard surface.

Figure 2-18 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.3.10 Dilatancy

The dilatancy of fine-grained soils can be determined through a dilatancy (shaking) test and described in accordance with Table 15. For a dilatancy test, water is dropped onto the sample while the soil is held in the palm of the hand until the sample shows a wet appearance on its surface when shaken or bounced. Then the soil should be lightly squeezed between the thumb and forefinger and released to observe its reaction. If the soil exhibits a dull dry surface upon squeezing and a glassy wet surface immediately upon releasing the pressure, the soil is considered to have rapid dilatancy that is typical of silty (nonplastic to low plasticity) soils.

**Table 15. Dilatancy**

Description	Criteria
None	No visible change in the specimen
Slow	Water appears slowly on the surface of the specimen during shaking and does not disappear or disappears slowly upon squeezing
Rapid	Water appears quickly on the surface of the specimen during shaking and disappears quickly upon squeezing

Figure 2-19 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.3.11 Toughness

The toughness of fine-grained soils can be described in accordance with Table 16. A sample should be rolled by the palm of the hand on a smooth surface to a thread about 1/8-inch diameter. Fold and reroll the sample threads repeatedly until the thread crumbles at a diameter of about 1/8-inch to assess the soil's toughness at the plastic limit.

**Table 16. Toughness**

Description	Criteria
Low	Only slight pressure is required to roll the thread near the plastic limit. The thread and the lump are weak and soft.
Medium	Medium pressure is required to roll the thread to near the plastic limit. The thread and the lump have medium stiffness.
High	Considerable pressure is required to roll the thread to near the plastic limit. The thread and the lump have very high stiffness.

Figure 2-20 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.3.12 Cementation

The cementation of intact coarse-grained soils can be described using Table 17.

**Table 17. Cementation**

Description	Criteria
Weak	Crumbles or breaks with handling or light finger pressure.
Moderate	Crumbles or breaks with considerable finger pressure.
Strong	Will not crumble or break with finger pressure.

Figure 2-22 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.3.13 Percent of Cobbles and Boulders

Particles greater than 3 inches in diameter are identified and described as "COBBLES," or "BOULDERS," or "COBBLES and BOULDERS". Cobbles and boulders must be reported by volume percentage (to the nearest 5%).

Isolated boulders may be treated as individual units and described as such. If the predominant constituent of the layer is estimated to be cobbles and/or boulders, the group name must be "COBBLES" or "BOULDERS" or "COBBLES and BOULDERS" with the matrix soil description following. There is no group symbol for cobbles and/or boulders.

#### 4.2.3.14 Description of Interbedded Soil

For interbedded soils, state the predominant soil group name and symbol followed by the bedding thickness of the components and the group name and symbol of the secondary layers. The bedding thickness categories are shown in Table 18.

**Table 18. Bedding Spacing**

Description	Thickness/Spacing, Sb
Massive	10 ft. < Sb
Very Thickly Bedded	3 ft. < Sb ≤ 10 ft.
Thickly Bedded	1 ft. < Sb ≤ 3 ft.
Moderately Bedded	4 in. < Sb ≤ 1 ft.
Thinly Bedded	1 in. < Sb ≤ 4 in.
Very Thinly Bedded	1/4 in. < Sb ≤ 1 in.
Laminated	Sb ≤ 1/4 in.

Figure 2-30 from Soil and Logging, Classification and Presentation Manual (Caltrans, 2010).

#### 4.2.3.15 Description of Fills

Fill materials are distinct from native soils in that they are artificial and should be documented for their thickness and soil type. Fill can consist of typical soils in addition to construction and paving remnants. While logging, write the word "FILL" in parenthesis after the soil description and include comments for additional materials in the soil description such as the presence of asphalt fragments or debris. For complex fills (e.g. interbedded and highly variable soil with multiple particle sizes), state the predominant soil group name and symbol followed by the layer thickness.

#### 4.2.3.16 Additional Comments

Additional comments that may be noted if encountered may include:

- Amount of roots or root holes
- Amount of mica, gypsum, etc.
- Presence of voids
- Surface coatings on coarse-grained particles
- Oxide staining
- Odor
- Cementing agents (e.g. calcium carbonate)
- Geologic formation name or soil survey unit name

#### 4.2.3.17 Other Drilling Observations

Other observations that should be noted on the borehole log include:

- Caving or sloughing of borehole and the vertical extent of the occurrence
- Difficulty in drilling (rig chatter)
- Changes in drill cuttings
- Ground water inflow
- Loss and return of drill fluid circulation
- Changes in drilling methods

Classification of Soils per ASTM D2487 or D2488

Geologic Formation noted in bold font at the top of interpreted interval

Uncorrected Blowcounts for Modified California Liner Sampler shown in " ( ) "

Length of sample symbol approximates recovery length

**SAMPLER DRIVING RESISTANCE**

Number of blows with 140 lb. hammer, falling 30-in. to drive sampler 1-ft. after seating sampler 6-in.; for example,

Blows/ft	Description
25	25 blows drove sampler 12" after initial 6" of seating
50/7"	50 blows drove sampler 7" after initial 6" of seating
Ref/3"	50 blows drove sampler 3" during initial 6" seating interval (Ref=Refusal)

**STRENGTH TEST METHOD**

UC = Unconfined Compression  
TXUU = Unconsolidated Undrained Triaxial  
TXCU = Consolidated Undrained Triaxial  
tv = Pocket Torvane  
pp = Pocket Penetrometer  
FV = Field Vane Shear Test

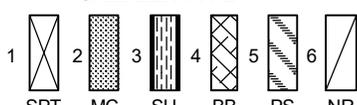

**OTHER TESTS**

k = Permeability  
Consol = Consolidation  
Gs = Specific Gravity  
MA = Particle Size Analysis  
PM = Pressuremeter  
EI = Expansion Index  
LEL = Lower Explosive Limit  
OXY = Oxygen Level Reading (%)  
OVM = Organic Vapor Measurement  
CR = Corrosion  
Abr. = SAT - Soil Abrasion Test

**WATER LEVEL SYMBOLS**

∇ Measured Depth to Water at Time of Drilling

**SAMPLER TYPE**

1 SPT  
2 MC  
3 SH  
4 BB  
5 PS  
6 NR

Samplers and sampler dimensions (unless otherwise noted in report text) are as follows:

1 SPT Sampler, driven 1 3/8" ID, 2" OD	4 Bulk Bag Sample (from cuttings)
2 MOD CA Liner Sampler 2.416" ID, 3" OD	5 Pitcher Sample
3 Shelby Thin-walled Tube, pushed 2 7/8" ID, 3" OD	6 No Recovery

**SOIL STRUCTURE**

Fissured: Containing shrinkage or relief cracks, often filled with fine sand or silt, usually more or less vertical.

Pocket: Inclusion of material of different texture that is smaller than the diameter of the sample.

Parting: Inclusion less than 1/8 inch thick extending through the sample.

Seam: Inclusion 1/8 inch to 3 inches thick extending through the sample.

Layer: Inclusion greater than 3 inches thick extending through the sample.

Laminated: Soil sample composed of alternating partings or seams of different soil types.

Interlayered: Soil sample composed of alternating layers of different soil type.

Homogeneous: Uniform composition

CONSISTENCY			RELATIVE DENSITY		INCREASING VISUAL MOISTURE CONTENT
Clays	Blows/Foot SPT	Pocket Penetrometer (tsf)	Sands and Gravels	Blows/Foot SPT	
<b>Very Soft</b>	< 2	0 - 0.25	<b>Very Loose</b>	0 - 4	↓ Dry Moist Wet
<b>Soft</b>	2 - 4	0.25 - 0.5	<b>Loose</b>	4 - 10	
<b>Medium</b>	4 - 8	0.5 - 1	<b>Medium Dense</b>	10 - 30	
<b>Stiff</b>	8 - 15	1 - 2	<b>Dense</b>	30 - 50	
<b>Very Stiff</b>	15 - 30	2 - 4	<b>Very Dense</b>	Over 50	
<b>Hard</b>	> 30	Over 4			

Information on each boring log is a compilation of subsurface conditions and soil or rock classifications obtained from the field as well as from laboratory testing of samples. Strata have been interpreted by commonly accepted procedures. The stratum lines on the logs may be transitional and approximate in nature. Water level measurements refer only to those observed at the time and places indicated, and can vary with time, geologic condition, or construction activity.

## TERMS AND SYMBOLS USED ON BORING LOGS

## **APPENDIX B**

### **FIELD SAMPLING FORMS**

1. Daily Equipment Calibration Log
2. Waste Tracking Log
3. Bank Erosion Hazard Index
4. Structural Inspection Form
5. Physical Shoreline Inspection Form
6. Near-Bank Stress Risk

(Individual SOPs also include forms to be used, which are not listed here)

*This page was intentionally left blank.*

**Worksheet 3-11.** Form to calculate an overall Bank Erosion Hazard Index (BEHI) rating. Use **Figure 3-7** to determine individual BEHI scores.

<b>Bank Erosion Hazard Index (BEHI)</b>										
Stream:					Location:					
Station:					Observers:					
Date:	Stream Type:			Valley Type:						
<b>Study Bank Height to Bankfull Height ( C )</b>										
Study Bank Height (ft) =		<b>(A)</b>			<b>(B)</b>			<b>(C)</b>		<b>BEHI Score</b> <small>(Fig. 3-7)</small>
Root Depth (ft) =		<b>(D)</b>			<b>(A)</b>			<b>(E)</b>		
Root Density as % =		<b>(F)</b>			<b>(G)</b>			<b>(G)</b>		
<b>Bank Material Adjustment:</b>										
<b>Bedrock</b> (Overall Very Low BEHI)						<div style="display: flex; align-items: center; justify-content: center;"> <div style="font-size: 2em; margin-right: 10px;">➔</div> <div style="border: 1px solid black; padding: 5px;"> <b>Bank Material Adjustment</b> </div> </div>				
<b>Boulders</b> (Overall Low BEHI)										
<b>Cobble</b> (Subtract 10 points if uniform medium to large cobble)										
of bank material that is composed of sand										
<b>Sand</b> (Add 10 points)						<div style="display: flex; align-items: center; justify-content: center;"> <div style="font-size: 2em; margin-right: 10px;">➔</div> <div style="border: 1px solid black; padding: 5px;"> <b>Bank Material Adjustment</b> </div> </div>				
<b>Silt/Clay</b> (no adjustment unless primarily clay, then subtract 20 points)										
						<div style="display: flex; align-items: center; justify-content: center;"> <div style="font-size: 2em; margin-right: 10px;">➔</div> <div style="border: 1px solid black; padding: 5px;"> <b>Bank Material Adjustment</b> </div> </div>

Structural Inspection Form  
**SIB** Project Area, Portland Harbor Superfund Site

This field form was developed from the *Waterfront Facilities Inspection and Assessment* (ASCE, 2015) (Manual). An assessment using this form must be completed for each structure along the river bank with different physical and material characteristics because of the unique potential for instability each structure possesses. The level of inspection performed will be a non-destructive level 1 inspection. For further detail regarding Structural Inspection requirements, please refer to Section 3.2.2.2 of the Manual. As needed, information to complete this form may need to be obtained from topographic or bathymetric surveys or from available online reference for Portland Harbor, such as USGS gauging stations.

Physical Shoreline Inspection Form  
**SIB** Project Area, Portland Harbor Superfund Site

This field form was developed from the *Guidance for River Bank Characterizations and Evaluations at the Portland Harbor Superfund Site* (USEPA, 2019) (Guidance). An assessment using this form must be completed for each geomorphic area or segment of the river bank with different physical and material characteristics because of the unique potential for erodibility each segment possesses. For further detail regarding Physical Shoreline Inspection requirements, please refer to Section 2.3 of the Guidance. As needed, information to complete this form may need to be obtained from topographic or bathymetric surveys or from available online reference for Portland Harbor, such as USGS gauging stations.

**WASTE MANAGEMENT PLAN  
SWAN ISLAND BASIN PROJECT AREA  
PORTLAND HARBOR SUPERFUND SITE  
PORTLAND, MULTNOMAH COUNTY, OREGON**

## **1.0 INTRODUCTION**

The Waste Management Plan (WMP) describes the procedures for safe handling, storage, transport, and disposal of investigation-derived wastes (IDW) generated during fieldwork. Wastes that are expected to be generated include excess sediments and/or soil from sampling, decontamination water, PPE and disposable sampling equipment, and municipal waste.

The following general guidelines will be followed to minimize the volume of waste streams generated during the project:

- Hazardous wastes will not be combined with non-hazardous wastes, and non-hazardous wastes will not be combined with non-contaminated wastes; waste types will be segregated so wastes are not unnecessarily managed or disposed;
- Cleaning and extra sampling supplies will be maintained outside potentially contaminated area to keep them clean and to minimize additional waste generation;
- Work will be planned ahead; selection of drilling locations, drilling methods, and sampling methods can help to reduce the amount of waste generated;
- Material and equipment will be decontaminated and reused when practical;
- Waste should be packed appropriately to minimize the number of containers. Bins containing soil should not be filled more than  $\frac{1}{2}$  to  $\frac{2}{3}$  full to avoid exceeding U.S. Department of Transportation (DOT) transport weight requirements;
- Appropriate waste containers, adequate to contain the volume of waste generated, will be used;
- Use of hazardous substances will be minimized; only the volume of standard solutions needed for testing will be brought, and minimal amounts of decontamination water will be used.

Work closely with you HydroGeoLogic, Inc. (HGL) Waste Manager (WM), Jody Sanchez, to ensure all waste is managed within the requirements of this plan.

*This page was intentionally left blank.*

## **2.0 CHARACTERIZATION AND SAMPLING**

Waste generated from investigation activities that is not considered municipal solid waste (MSW) will undergo a waste-stream-specific hazardous waste determination for disposal at a Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Office of Solid Waste (OSR) approved landfill in accordance with 40 CFR 300.440. Off-site treatment or disposal facilities will use the waste profile and supporting documentation, such as analytical data, to determine whether a waste meets the waste acceptance criteria. It is anticipated that sediment and decontamination water generated during the field activities will be characterized as nonhazardous. Additionally, the quantity of general waste will be estimated and the most cost-efficient method for containment will be determined.

Oregon Administrative Rule (OAR) 340-101-0033 lists wastes that are State-only hazardous wastes. State only hazardous wastes include pesticide residues and mixtures of wastes containing constituents of Federal P (3 percent [%]) & U (10%) listed wastes (see lists in 40 CFR 261.31 and 261.32).

The sampling procedures and analytical requirements are described below.

### **2.1 SOIL AND SEDIMENT**

Solid waste samples for characterization will be collected according to the following guidelines. Off-site treatment or disposal facilities may have different sampling requirements.

- One 5-point composite sample will be collected per 10 drums, per location and/or area for nonvolatile wastes;
- A single grab sample will be collected for volatile wastes. The grab sample will be collected from the drum that contains the location with the highest photoionization detector (PID) readings, or other indications of contamination.
- Analysis for each waste stream from each site will be based onsite history and potential constituents of concern for the Site. Analyses will be conducted in accordance with the methods and procedures outlined in the Worksheet #12 and #15 of the Uniform Federal Policy (UFP)-Quality Assurance Project Plan (QAPP).

Potential waste characterization analysis parameters for solid media include the following:

- Volatile Organic Compounds (VOCs);
- Semi-Volatile Organic Compounds (SVOCs);
- Polycyclic Aromatic Hydrocarbons (PAHs)
- Herbicides;
- Pesticides;
- Resource Conservation and Recovery Act (RCRA) Metals;
- Polychlorinated Biphenyls (PCBs);
- Dioxins and Furans;

- pH;
- Flashpoint.

Additional parameters may be required by the disposal facility and will be added accordingly. Samples for toxicity characteristic leaching procedure (TCLP) analyses will be collected and put on hold. If any of the analytical results exceed 20x the TCLP waste criteria, these analyses will be conducted.

The waste characterization sample will be obtained from a container as follows:

- Procedure for Collecting Volatile Fractions:
  1. Using a hand auger or other device, retrieve a core from the container;
  2. Remove the core from the auger or other device using a disposable Terra Core sampler and place the sample into pre-preserved volatile organic analysis vials. The transfer operation should be completed in one minute or less to minimize loss of volatile components;
- Procedure for Collecting Non-Volatile Fractions:
  1. Collect several spoonfuls of the soil into a stainless steel bowl from five randomly selected sample locations and depths;
  2. Homogenize the five grab samples by quartering techniques using the stainless steel spoon;
  3. Fill the appropriate sample jars completely full of the homogenized sample;
  4. Close the jar, label the jar, and package the sample for shipment to the laboratory.

## **2.2 WASTEWATER CHARACTERIZATION SAMPLING**

Wastewater samples for characterization will be collected according to the following guidelines. Off-site treatment or disposal facilities may have different sampling requirements.

- One composite sample will be collected per 10 drums, per location and/or area for non-volatile wastes;
- A single grab sample will be collected for volatile wastes. The grab sample will be collected from the drum that contains the location with the highest PID readings, or other indications of contamination.

Analysis for each waste stream, for each investigation activity, will be based on-site history and potential constituents of concern for the Site. Analyses will be conducted in accordance with the methods and procedures outlined in the UFP-QAPP HGL, (2021).

Potential waste characterization analysis parameters for wastewater include the following:

- VOCs;
- SVOCs;

- PAHs;
- Herbicides;
- Pesticides;
- RCRA Metals;
- PCBs;
- Dioxins and Furans;
- pH.

Additional parameters may be required by the disposal facility and will be added accordingly.

Wastewater analytical results are directly comparable to the TCLP criteria; TCLP analyses will not be conducted on liquid samples unless the percent solids is greater than or equal to 0.5%.

The waste characterization sample will be obtained from a container as follows:

1. Collect a water sample from the container using a bailer or dip jar;
2. Fill the grab sample containers for VOC analysis first. Fill the containers so that there is no headspace;
3. Fill the sample containers for the remaining analyses;
4. Label and package the samples for shipment to the laboratory.

*This page was intentionally left blank.*

### **3.0 GENERAL WASTE MANAGEMENT**

Wastes will be managed as hazardous if identified as containing a listed hazardous waste, or until analytical results are received and the waste is characterized as nonhazardous. Potentially hazardous wastes that are more-obviously highly contaminated, as evidenced by visual, olfactory, or vapor screening criteria, will be managed in separate containers from less-obviously contaminated wastes of the same media. All wastes will be containerized, and a waste determination made before it is disposed of at an appropriate waste facility. Waste disposal will occur as described below and is also addressed the Investigation Derived Waste Instructions Scope of Services (SOS) for further information (September 2020; Appendix D).

Any excess water or sediment spilled on the deck of the sampling vessel will be washed into the surface waters at the collection on-site before proceeding to the next station.

Phosphate-free detergent-bearing liquid wastes from decontamination of the sampling equipment will be sampled for site contaminants of concern. If discharge to a sanitary sewer system is identified as the most cost-effective method, the appropriate representative at the Portland Bureau of Environmental Services will be identified to request permission to discharge.

Due to the nature of the contaminants of concern at this site disposable or expendable materials such as Tyvek, gloves, sampling spoons, paper towels, plastic sheeting, and other used sampling material generated during sampling will be placed in drums for disposal at as nonhazardous waste at a Subtitle D (nonhazardous) landfill. Used core tubes will be decontaminated and then recycled to prevent potential further contamination at the waste facility.

In general, waste containing  $\geq 50$  ppm PCBs may be stored onsite for 180 days from the date of generation, as indicated under 40 CFR 761.65(c)(9) for PCB bulk product waste and PCB remediation waste. PCB-contaminated media is regulated as bulk PCB remediation waste and requires characterization for disposal. Final disposition is based on the as-found concentrations of PCBs within the media. If PCB concentrations exceed 50 ppm, the waste is considered a federal Toxic Substances Control Act (TSCA) PCB waste and must be transported off-site to a Class 1 disposal facility (permitted by the Oregon Department of Environmental Quality) by a licensed hazardous waste transporter within 90 days of the accumulation start date.

A waste designation memo (as noted in the SOS), if appropriate, will describe the characterization of any RCRA wastes (evaluated as part of the Remedial Design) and present the data needs necessary to arrange for the off-site disposal of the wastes at an appropriate facility.

If hazardous waste material is in exceedance of 10 cubic yards, workers may ship the waste from the Site to an out-of-state waste management facility only if, prior to any shipment, they provide notice to the appropriate state environmental official in the receiving facility's state and to the U.S. Environmental Protection Agency (EPA) Project Coordinator. The notice must include the following information, if available: (1) the name and location of the receiving facility; (2) the type and quantity of waste material to be shipped; (3) the schedule for the shipment; and (4) the method of transportation. Respondents also shall notify the state environmental official referenced above and the EPA Project Coordinator of any major changes in the shipment plan, such as a decision to

ship the waste material to a different out-of-state facility. Respondents shall provide the notice as soon as practicable after the award of the contract and before the waste material is shipped. This notice requirement does not apply to any off-Site shipments when the total quantity does not exceed 10 cubic yards.

### **3.1 CONTAINERS AND ACCUMULATION**

Hazardous wastes, Oregon State Only hazardous wastes, and potentially hazardous wastes will be stored consistent with the applicable requirements of 40 CFR Part 262. Storage containers used for transportation of hazardous wastes will comply with the requirements of 49 CFR Part 178. All wastes will be containerized in United Nations (UN) certified, 55-gallon, steel drums (1A2).

The waste accumulation area is identified as the staging area at the Fred Divine Dock in coordination with the marine vessel subcontractor. Figure C-1 denotes the location of the primary waste accumulation area; an alternate waste accumulate area is shown in case there are logistical conflicts with the primary location. The field crew will use the waste accumulation area to process samples and drum waste for designation and disposal. Good housekeeping practices will be maintained at waste accumulation areas. Waste accumulation areas, as well as fuel and chemical storage areas, will be protected from on-site and off-site vehicle traffic. Also, the waste accumulation area will be constructed with a secondary containment system consisting of a plastic-lined area with 2x4s or waddles and/or a pre-constructed system.

Containers of hazardous, State Only, and potentially hazardous wastes will be inspected and documented weekly for evidence of deterioration or leaks. Containers will be appropriately labeled as containing hazardous waste and the accumulation start date will be noted. The amount of wastes generated, both hazardous and nonhazardous, during field work will be documented on a waste tracking log (WTL) (WTL, Appendix B of the FSP).

Hazardous wastes may be stored on-site or accumulated in containers for a maximum of 90 days. The 90-day period begins on the date the waste is first generated and containerized.

Waste accumulation areas will contain emergency response equipment appropriate for the hazards associated with the generated IDW. The project Health and Safety Plan (HASP) for the Site identifies the project emergency response procedures, equipment, contacts, and phone numbers. Hazardous waste storage areas will have fire extinguishers for wastes known or suspected to be flammable or ignitable; decontamination equipment including an eyewash station; and an alarm system, radio, or cell phone available to staff working in the hazardous waste accumulation area. Spill control equipment, such as sorbent pads, will be available in the waste accumulation areas and in places where liquids are transferred between vessels.

Waste accumulation areas will be inspected and documented for malfunctions, deterioration, discharges, and leaks. Inspections will be performed monthly at a minimum. Hazardous waste containers will be inspected at least weekly for leaks, corrosion, or general deterioration. Inspections will be documented on an inspection form and in the field notebook. Deficiencies will be corrected immediately. If field work suspends for more than 7 days, alternative arrangements for weekly inspection of the hazardous waste containers will be made. Prior to demobilization, hazardous wastes will be disposed of.

### **3.2 DRUM REQUIREMENTS**

The following guidelines relate to accumulation of waste in small containers such as 55-gallon drums:

- Only new UN-approved drums will be used. Reconditioned drums purchased from an outside source are not acceptable. It is acceptable to reuse new drums from the Site that are in good condition and have been steam cleaned or if wastes are solid and nonhazardous;
- Drums will be inspected and inventoried on arrival for signs of contamination and deterioration. Compromised drums will be rejected;
- Drums will have UN approval numbers embossed on the bottom or stenciled on the side, “1A2/Y1.7/150” for liquids and “1A2/X425/S” for solids;
- Drums should be removable-head-type drums without bungs. Bung holes in the lid are acceptable for special applications, but bung holes in the side of the drum are never acceptable;
- No penetrating dents are allowed that could affect the integrity of the drum. Pay special attention to any dents at the drum seams. Use the highest level of integrity standards for drums intended to contain liquids;
- Adequate aisle space, minimum 30 inches, will be provided for containers such as 55 gallon drums to allow the unobstructed movement of personnel and equipment. A row of drums should be no more than two drums wide;
- Each drum will be provided with its own label, and labels will be visible (facing into the aisle);
- Drum lids/bungs will remain covered/closed except when removing or adding waste to the drum. Lids should fit correctly, and the gasket must be in good condition. Lids/Bungs will be properly secured at the end of each workday. “Closed” means rings are on and bolts are tightened down. Lids and bungs will be tightened for transport as required by DOT shipping regulations;
- When drums are being filled, make sure there is only one (1) waste stream being placed in the drum. Do not overfill containers. If drums are stored on pallets make sure the pallets are undamaged.
- Drums will be disposed of with the contents. If the contents are removed from the drums for off-site transportation and treatment or disposal, the drums will be decontaminated prior to reuse or before leaving the Site. If drums are emptied and stored on-site, they will be labeled with the word “empty” and the date they were emptied. Empty drums should be removed from the site within one (1) year;
- Drums containing liquids or hazardous waste will be provided with secondary containment and may not be located near a stormwater inlet or conveyance;
- Secondary containment systems will have sufficient capacity to contain 10% of the volume of containers or the volume of the largest container, whichever is greater, plus

the maximum rainfall from a 25-year, 24-hour storm event. Spilled or leaked waste and accumulated precipitation will be removed from the sump or collection area in a timely manner to prevent overflow of the collection system;

- The outsides of the drums must be free of hazardous waste residues;
- If drums become damaged to begin to leak, the contents will be immediately transferred to another container and the drum removed from service or the drum can be overpacked.

### **3.3 MARKS AND LABELS**

Waste containers must be labeled in accordance with 49 CFR 172. Until wastes are characterized, they must be handled as if they are hazardous and an Analysis pending label will be placed on the container. Once the waste has been characterized as hazardous, state only hazardous, or nonhazardous, the container will be relabeled appropriately.

Waste will have visible labels. The labels will include the type of waste, location from which the waste was generated, name and phone number of the generator point of contact, and accumulation start date. Any information not known when waste containers are initially labeled will be added when the information is known. Waste labels must be visible, legibly printed or stenciled, and placed on the container in such a manner that labels and markings on all containers are readily visible for inspection.

#### **3.3.1 Analysis Pending Labels**

A “Waste Analysis Pending” label may be used until the waste is characterized. This is a temporary label until analytical results are received and reviewed and the waste characterized as hazardous, state only hazardous, or nonhazardous. Once the waste is characterized, this label will be replaced with a hazardous waste or nonhazardous waste label. The “Waste Analysis Pending” label will include the contents, name and phone number of the generator point of contact, and accumulation start date. Such waste will be appropriately staged/stored until appropriate waste classification determinations are made under appropriate criteria.

#### **3.3.2 Hazardous Waste Labels**

A “Hazardous Waste” preprinted waterproof label with the following container marking requirements provided in 49 CFR 172 and 40 CFR 262.31 and 262.32 will be attached to the drum, container, or tank containing wastes that are determined to be hazardous based on process knowledge or sampling information. Prior to transport for off-site disposal, appropriate waste codes, the proper DOT shipping name, and the manifest number will be added to the hazardous waste label. Hazardous waste labels will display the following information:

- Accumulation start date: (date waste was first placed in the container);
- Generator name: Swan Island Basin Remedial Design Group;
- Generator contact: (to be determined [TBD]);
- Generator contact phone number: (TBD);

- Generator address: (TBD);
- EPA identification (ID) number: (TBD);
- Waste codes;
- Description of waste, including hazardous properties and physical state;
- Proper DOT shipping name;
- Manifest number (added before transportation);
- The appropriate DOT hazard class label will be placed on the container before it is loaded onto the transport vehicle.

### 3.3.3 Nonhazardous Waste Label

A “Nonhazardous Waste” preprinted waterproof label with the following information will be attached to the drum, container, or tank containing wastes that are determined to be nonhazardous based on process knowledge or sampling information.

- Drum accumulations start date;
- Generator name, contact, and contact number;
- Waste-specific information (composition, origin of waste (boring or well number), and other information necessary to identify the waste).

Samples of container labels are shown below:

### 3.4 WASTE SHIPPING AND DOCUMENTATION

Records of waste materials removed from the Site will be maintained. A binder will be maintained at the Site exclusively for waste transfer activities and copies provided to the Remedial Program Manager (RPM) and HGL WM. Hazardous wastes transported, treated, stored, or disposed will be recorded and reported. The following documents, as applicable, are required:

- Information on waste packaging, container markings, labeling, and placarding of waste shipments;
- Waste container inventory and inspection records;
- Waste profile sheets;
- Analytical results;
- OSR approval confirmation;
- Hazardous waste manifests;
- Land Disposal Restriction (LDR) notification and certification forms;
- Nonhazardous manifests;
- Safety Data Sheets; where appropriate;
- Piece counts, weigh tickets, and bills of lading for non-contaminated wastes;
- Receipts for general solid waste disposal.

All wastes will be tracked. Documentation associated with waste disposal will be appended to the report after completion of the fieldwork.

#### **3.4.1 CERCLA OSR Confirmation**

The OSR approval for each facility will be confirmed every 60 days unless noted otherwise by the Regional OSR Contact (ROC). An email will be prepared and sent to the ROC for each facility to confirm OSR approval. The email will include the following information:

- Name of facility receiving the waste;
- City and state of facility receiving the waste;
- EPA ID;
- Name of facility generating the waste;
- Amount and type of wastes;
- Expected shipping date.

Upon receiving written acceptance of the waste by the selected treatment, storage, and disposal facility (TSDF), the WM will work with the waste subcontractor to prepare the manifest (or shipping papers) and other support documentation.

#### **3.4.2 Waste Profiling**

Waste characterization information will be used to complete the waste profile form) provided by the designated off-site treatment or disposal facility as part of the waste acceptance process. The profile will be reviewed and approved by the WM. After WM approval, waste documentation will be provided to the RPM for review and signature, as the waste generator. Signed profiles will then be submitted to the designated receiving facility for approval. The profile typically requires the following information:

- Generator information, including name, address, contact, and phone number;

- Site name, including street and mailing address;
- Process generating waste such as soil cuttings or water/soils generated during sampling;
- Source of contamination and historical use (historical releases and dumping);
- Waste composition; for example, 95% soil, 5% debris;
- Physical state of waste, such as solid or liquid;
- Applicable hazardous waste codes.

The waste will be transported to the TSDF in accordance with both Federal and State requirements. Waste will be delivered to the TSDF within 35 days from the date the transporter takes possession as indicated by signature on the complete manifest package. A 24-hour hotline will be established and made available to the transporter and TSDF to report any issues while the waste is in transit.

### **3.4.3 Waste Transport**

Prior to off-site disposal of any waste, a waste approval package for each waste stream will be prepared. This package will include a waste profile naming Swan Island Basin Remedial Design Group as the generator of the waste, an analytical summary table(s) applicable to the waste, LDR notification or certification for any hazardous wastes, a completed waste manifest, and any other applicable information necessary for Swan Island Basin Remedial Design Group personnel to complete the review of the disposal package and sign as the generator.

The signed profile will then be submitted to the designated off-site facility for acceptance and approval. Once the approval letter is received from the designated facility, transportation can be scheduled. A licensed waste transporter will be contracted to transport the containerized IDW to the selected TSDFs. The contracted transporter will have required licenses, registrations, and certifications for the specific waste stream to be transported.

Prior to contracting with the hazardous waste transporter, the name, location, point of contact, EPA ID number, verification that the transporter is licensed to haul hazardous waste, and notice of violation status will be provided to the WM for approval. Prior to disposal or shipment off-site, the waste disposal subcontractor will label the drums with the appropriate DOT ID and classification information as required by applicable sections of 49 CFR, Parts 171, 172, 173, 178, and 179.

Waste transporters will cover loads and each truck will be inspected to verify the loads are secure, proper placarding is provided as necessary, and shipping documentation is accurate. In addition, the waste transporter will confirm that the vehicles are not leaking or releasing waste constituents from loading at the source site, along the haul route, and offloading at the approved disposal site.

Each transportation vehicle and load of waste will be inspected before leaving the Site and documented. The quantities or estimated quantities of waste leaving the Site will be recorded on the WTL. A contractor licensed for commercial transportation will transport nonhazardous wastes. In the event that wastes are hazardous, the transporter will have an EPA ID number and will comply with transportation requirements outlined in 49 CFR 171-179 (DOT); and 40 CFR 263.11 and 263.31 (Hazardous Waste Transportation).

Drivers of off-site disposal trucks must not come in physical contact with the contaminated material while covering the load or preparing it for transport. The transporter and field team leader will verify that there is no visible soil/waste material on the sides or tires of any trucks leaving the Site. Proper decontamination procedures will be used to remove soil or debris from the outsides of the vehicles, if necessary, to prevent soil from being tracked beyond designated work areas. The transporter will observe the following practices when hauling and transporting wastes off-site:

- Minimize impacts to general public traffic;
- Repair road damage caused by the transporter;
- Clean up waste spilled in transit;
- Line and cover trucks/trailers used for hauling contaminated waste to prevent releases and contamination;
- Decontaminate vehicles prior to reuse;
- Ensure that seals on trucks transporting liquids are in good condition;
- Ensure that no materials from other projects are combined with materials from this Site;
- Ensure that personnel involved in off-site disposal activities follow safety and spill response procedures outlined in the HASP and Emergency Response Plan.

#### **3.4.4 Shipment Methods**

Waste shipments will comply with procedures specified in the Hazardous Materials Transportation Act, 49 CFR 171. Hazardous materials will be properly classified, described, packaged, marked, and labeled for shipment as required by 49 CFR. Any hazardous material identified as a marine pollutant that is hauled in bulk will comply with the Marine Pollutant Act (49 CFR 171.4[c]). A bulk package for solids is defined as having a maximum net mass of 882 pounds or more and a maximum capacity of 119 gallons or more. Packaging and labeling of waste will be performed by staff trained to meet the DOT requirements (for example, hazardous materials employee training requirements under 49 CFR 172 Subpart H).

#### **3.4.5 Nonhazardous Waste Record**

Each load of nonhazardous waste will be shipped using a Nonhazardous Waste Record. At a minimum, the form will include the required fields (quantity of waste and disposal location) with the possibility of the following additional information:

- Generator information, including name, address, contact, and phone number;
- Transporter information, including name and phone number;
- Designated facility information, including name, address, and phone number;
- Site name, including street/mailing address;
- Type and number of containers;
- Task order or job number;
- Profile number; and
- 24-hour emergency phone number.

The generator and the transporter must sign the manifest prior to the load of waste leaving the Site. The original signed manifest will be returned to the address of the generator.

### **3.4.6 Municipal Solid Waste, Construction and Demolition Debris, and Recyclables**

MSW and construction and demolition debris that will be disposed of off-site as well as recyclables will be shipped under a nonhazardous manifest or a bill of lading. Quantities and shipments will be tracked on the WTL.

### **3.4.7 Hazardous Waste and PCB Waste**

Each load of hazardous waste, Oregon State Only hazardous waste, and PCB waste (as specified in TSCA) will be manifested on a hazardous manifest prior to leaving the Site. At a minimum, the manifest form will include the following information:

- Generator information, including name, address, contact, phone number, and EPA ID number;
- Transporter information, including name, address, contact, phone number, and EPA ID number;
- Designated facility information, including name, address, phone number, and EPA ID number;
- Site name, including street/mailling address;
- Proper DOT shipping name; for example, Hazardous Waste Solid, n.o.s., 9, UN 3077, PG III [D008];
- Type and number of containers;
- Quantity of waste (volumetric estimate);
- Task order or job number;
- Profile number;
- 24-Hour emergency phone number.

The generator and the transporter must sign the manifest prior to the load of waste leaving the Site. The original signed manifest will be returned to the address of the generator and a photographed and/or scanned copy saved to the HGL project files.

Additionally, each shipment of waste will also have a weight ticket. An LDR Notification/Certification is required for hazardous wastes. This form also requires the generator's signature, and submission to the designated facility.

If the signed hazardous waste manifest from the designated facility is not received within 35 days, HGL will contact the transporter or the designated facility to determine the status of the waste. If the signed hazardous waste manifest has not been received within 45 days, an "Exception Report" must be prepared and submitted to EPA.

### **3.5 TRAINING**

Field staff that will manage hazardous or potentially hazardous waste will meet the hazardous waste generator training requirements of 40 CFR 265.16 through the following:

- Occupational Safety and Health Administration 29 CFR 1910, Section 120, hazardous waste operations and emergency response training;
- On-the-job training, which includes:
  - Site-specific HASP review: requires each site worker, and guests to review and sign the plan
  - Activity hazard analysis and daily “tailgate” meetings
  - Project-specific Work Plan review
- Hazardous waste generator training requirements of 40 CFR 265.16, including the following:
  - Documented annual training provided by qualified instructor
  - Project-specific WMP review
- DOT training per 49 CFR 172, Subpart H, as appropriate, for those performing the following functions:
  - Selecting and marking packaging or container for hauling
  - Preparing hazardous materials for transportation
  - Loading, unloading, or handling hazardous materials
  - Operating a vehicle used to transport hazardous materials
  - Preparing or reviewing hazardous materials shipping papers, including hazardous waste manifests

## **4.0 DOCUMENTATION**

HGL will retain copies of profiles, weight tickets, transporter-signed and fully executed waste manifests, LDRs, and waste analysis records discussed in this WMP for each waste shipment in the project records for three (3) years. Documentation of soil transported off-site will be kept on-site or in the project records for a minimum of three (3) years. The following transportation and off-site disposal records and documents will be maintained at the project site:

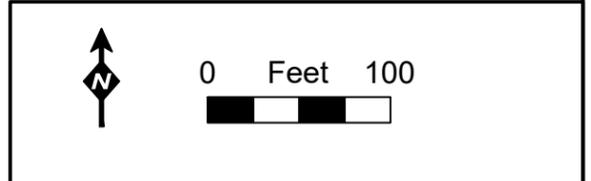

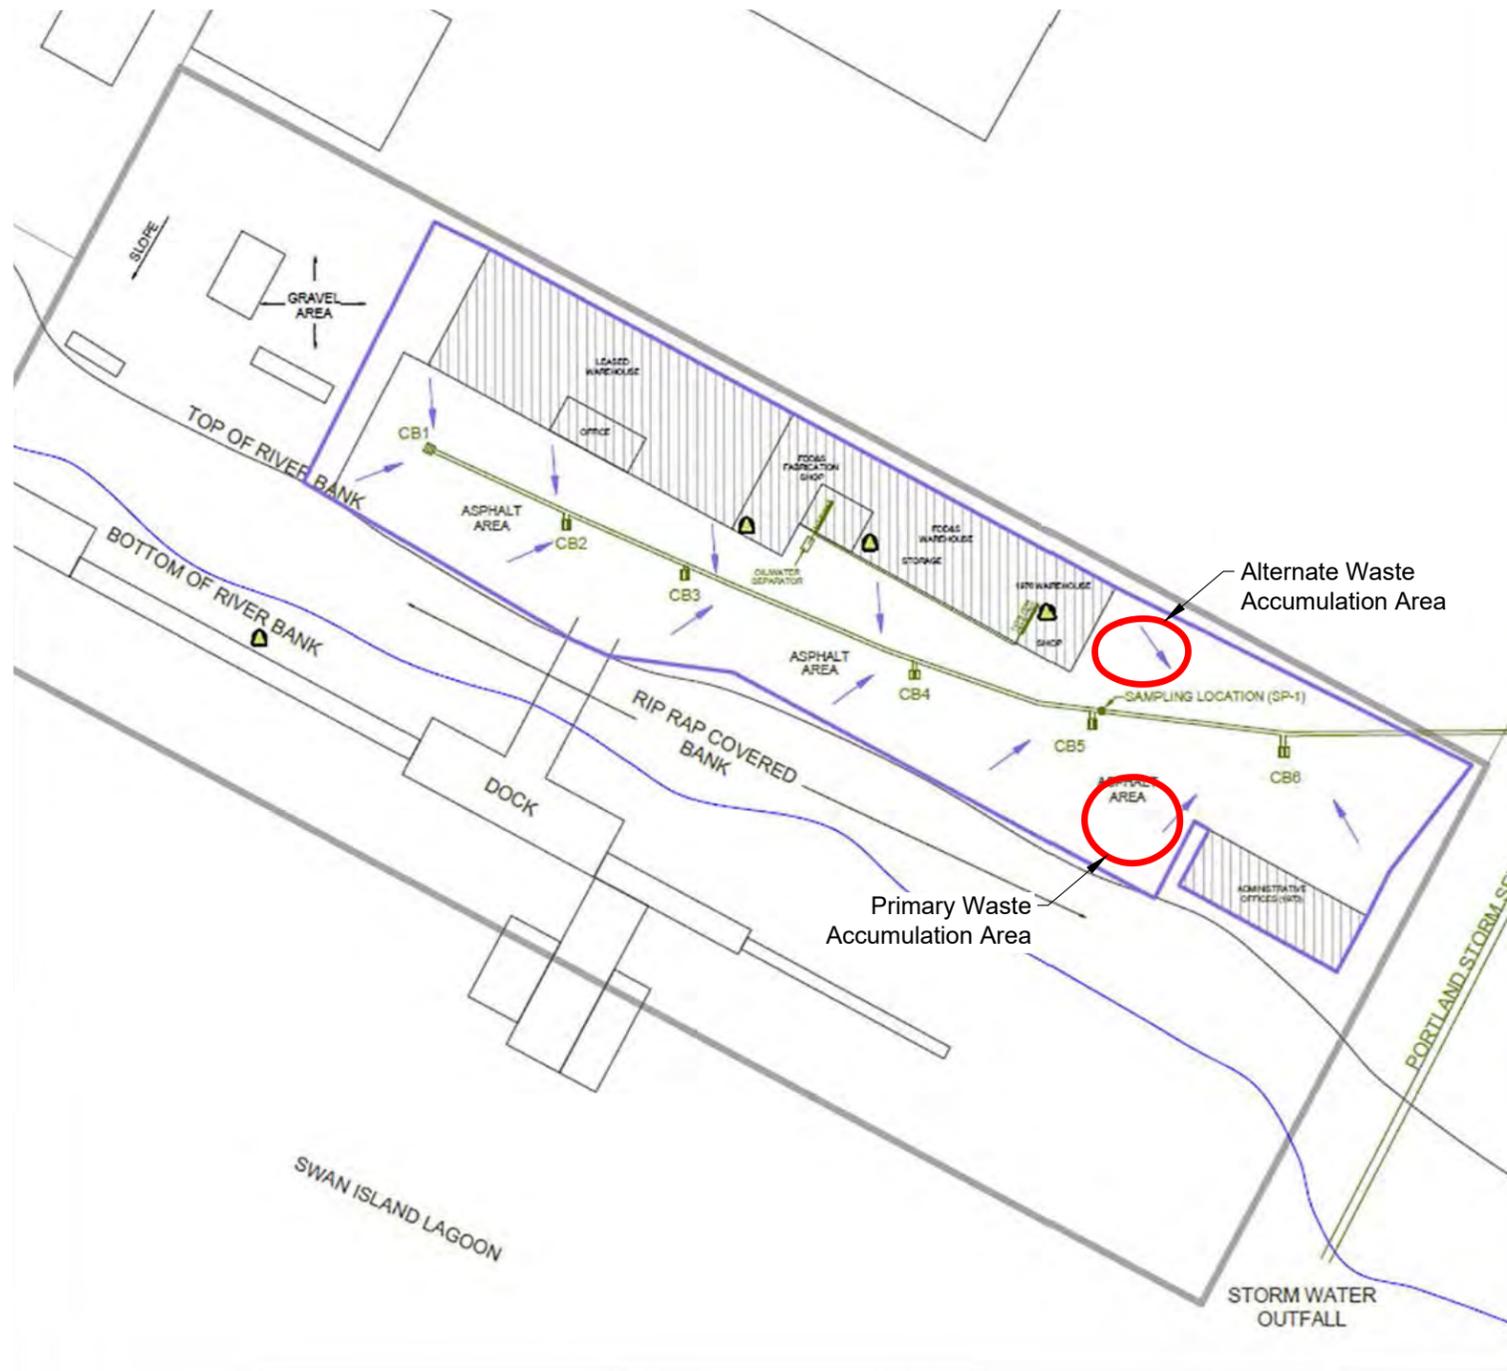

- Profiles and associated characterization data
- Manifests, LDR notifications and certifications, bills of lading, and weight tickets
- Off-site facility waste receipts and certificates of disposal, destruction, or recycling
- Inspection records, including weekly inspections of waste accumulation areas, and inspections of permitted units in accordance with the permit requirements
- Waste tracking logs
- Training records for each individual involved with the management of or occupationally exposed to hazardous waste, including the employee's job title related to each position, the name of the employee filling the position, a written job description, a written description of the type and amount of training required, and documentation that the training has been provided.

Copies of all documentation will be provided to EPA.

**UNIFORM FEDERAL POLICY-QUALITY ASSURANCE PROJECT PLAN  
REMEDIAL DESIGN SERVICES  
SWAN ISLAND BASIN PROJECT AREA  
PORTLAND HARBOR SUPERFUND SITE  
PORTLAND, MULTNOMAH COUNTY, OREGON**

**INTRODUCTION**

This Uniform Federal Policy (UFP)-Quality Assurance Project Plan (QAPP) has been prepared by HydroGeoLogic, Inc. (HGL) to present the requirements for the collection of data to support the Remedial Design (RD) services for the Swan Island Basin (SIB) Project Area of the Portland Harbor Superfund Site (PHSS) in Portland, Multnomah County, Oregon. This work will be completed in accordance with the requirements of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), the PHSS Record of Decision (ROD) (U.S. Environmental Protection Agency [EPA], 2017) including Errata 1 (EPA, 2018) and Errata 2 (EPA, 2020), the Explanation of Significant Differences (EPA, 2019), and the Administrative Settlement Agreement and Order on Consent (ASAOC) (EPA, 2021).

This UFP-QAPP is intended to be used in conjunction with the Field Sampling Plan (FSP) (HGL, 2021a) for the SIB Project Area. This document meets the requirements and elements set forth in the Intergovernmental Data Quality Task Force (IDQTF) guidance document titled *Uniform Federal Policy for Quality Assurance Project Plans* (IDQTF, 2005) with the optimized worksheets developed in 2012 (IDQTF, 2012). This UFP-QAPP is specific to the SIB Project Area. It also includes supplemental information and requirements as necessary to support project-specific objectives.

**WORKSHEETS #1 AND #2**

**WORKSHEETS #1 AND #2 (CONTINUED)**  
**TITLE AND APPROVAL PAGE**

**Site Name/Project Name:** RD, SIB Project Area, PHSS

**Site Location:** Portland, Multnomah County, Oregon

**Contractor Name:** HGL

**Contract Number:** DT2002

1. Identify guidance used to prepare the QAPP: EPA Requirements for Quality Assurance Project Plans, QA/R-5, EPA/240/B-01/003 (EPA, 2001); Guidance for Quality Assurance Project Plans, QA/G-5, EPA/240/R-02/009 (EPA, 2002); and UFP-QAPP, Parts 1-3, EPA/505/B-04/900A through 900C (IDQTF, 2005) and Optimized Worksheets (IDQTF, 2012).
2. Identify regulatory program: The SIB Project Area being addressed under CERCLA. EPA Region 10 is the lead regulatory agency for the SIB Project Area.
3. Identify approval entities: EPA Region 10, see approval signature on Page 1 of Worksheet #1 and #2.
4. The QAPP is: Project specific.
5. List dates of scoping sessions that were held: The Kick-off Technical Working Group Meeting was held on May 12, 2021.
6. List dates and titles of QAPP documents written for previous site work, if applicable:
  1. Quality Assurance Project Plan, Swan Island Lagoon, Sediment Sampling Investigation, Portland Harbor Superfund Site (Pacific Groundwater Group [PGG], 2018).
7. List organizational partners (stakeholders): EPA Region 10; Oregon Department of Environmental Quality (ODEQ); The Yakama Nation; The Five Tribes; and the Settling Federal Agencies, Settling Public Entities, and Respondents indicated in the ASAOC.
8. List data users: EPA Region 10; ODEQ; the Respondents indicated in the ASAOC; and the SIB RD Group contracted to the Respondents.
9. If required UFP-QAPP elements and required information are not applicable to the project, then circle the omitted UFP-QAPP elements and provide the required information on the attached table. Provide an explanation for their exclusion below: All UFP-QAPP worksheets are applicable.

**WORKSHEETS #3 AND #5**  
**PROJECT ORGANIZATION AND QAPP DISTRIBUTION**

**Distribution:**

The following is the distribution list for the UFP-QAPP for RD at the SIB Project Area.

**WORKSHEETS #3 AND #5 (CONTINUED)**  
**PROJECT ORGANIZATION AND QAPP DISTRIBUTION**

**Responsibilities:**

Role	Responsibilities
<b><i>EPA Regulatory Program</i></b>	
EPA Region 10 RPM	Lead responsibility for developing and implementing community involvement activities. Has the authority as a RPM and/or an on-scene coordinator, as described in the NCP, including the authority to halt the work and/or to conduct or direct necessary response action when they determine that conditions at the SIB Project Area constitute an emergency or may present an immediate threat to public health or welfare or the environment due to a release or threatened release of waste material.
<b><i>Respondents Client Management Team</i></b>	
Project Coordinator	Serve as coordinating POC within the CMT and between EPA and the RD Group. Responsible for meeting monthly with the EPA RPM.
CMT Members	Represent the interest of the individual respondents and the CMT.
<b><i>RD Group Project Management Team and Project Staff</i></b>	
Principal-in-Charge (HGL)	Responsible for performance for the contract; ensures that HGL meets its performance objectives and contractual requirements.
Senior PM (HGL)	Responsible for overall project coordination and oversight on project deliverables. POC for information to and from DTNA and regulatory agencies. Oversees and coordinates SIB field and reporting activities with the project team and subconsultants.
Deputy PM (HGL)	Performs responsibilities of the Senior PM during Senior PM absence and as delegated by the Senior PM.
Technical Director (HGL)	Oversees technical aspects of project planning, sample collection, reporting, and data evaluation activities to ensure compliance with the project objectives.
Technical Leaders (Team Member: PGG, Mott MacDonald and Bridgewater Group)	Guides project activities assigned to their firms to ensure compliance with the project objectives.
QA Officer (HGL)	Responsible for ensuring the quality of planning and design deliverables and of technical services. Oversees project audit activities.
Health and Safety Officer (HGL)	Reviews planned field activities to ensure that site operations are performed in accordance with HGL, SIB Project Area, and regulatory safety requirements.
<b><i>RD Group Technical Team</i></b>	
Sampling and Analysis Coordinator	Contacts the laboratory to order sample containers and equipment prior to sampling events. Reviews CoCs against laboratory sample receipt and the event sampling plan. Resolves discrepancies with the laboratory and refers issues to the Chemistry QA Manager for resolution. Provides hard copy laboratory reports to the data validator and EDDs to the data manager.
Chemistry QA Manager	Author or approval of UFP-QAPP. Serves as primary POC for the laboratory to report data quality and other analytical issues and responsible for resolution. Provides chemistry and analytical guidance to the project team to ensure that data quality will meet the intended end use. Reviews or oversees the review of subcontracted data validation reports and evaluates overall data usability against DQOs.

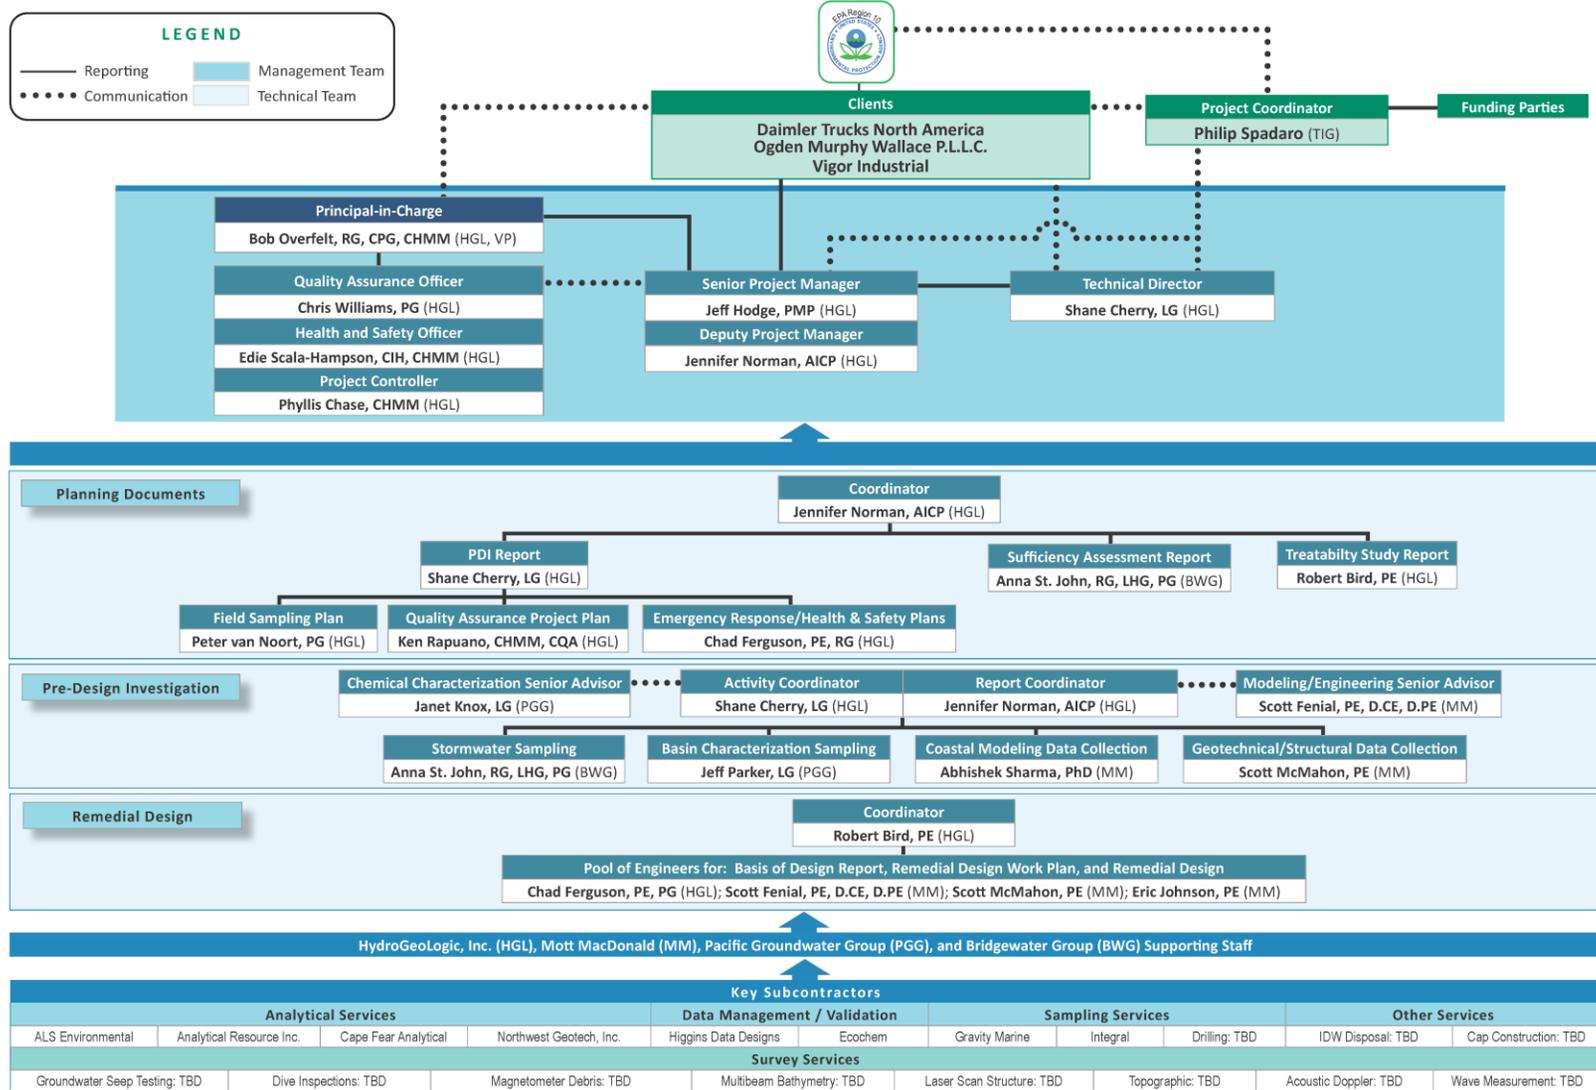

**WORKSHEETS #3 AND #5 (CONTINUED)**  
**PROJECT ORGANIZATION AND QAPP DISTRIBUTION**

<b>Role</b>	<b>Responsibilities</b>
Data Manager	Ensures that laboratory EDDs are properly formatted and complete. Uploads laboratory EDD's and field data into the project database. Assists the project chemistry and technical team members in retrieving and formatting data for use and presentation.
Site Manager	Serves as the coordinator for field activities within the Design team and the SIB Project Area occupants. Ensures that sampling activities are performed in accordance with HGL, project, and SIB Project Area requirements.
FTL	Oversees sampling events in the field. Responsible for the complete collection of samples for all parameters in accordance with project, SIB Project Area, and regulatory requirements. Ensures field team compliance with applicable safety requirements and good technical practices.
Sampling Vessel Leader	Serves as the overall authority for vessel-based project activities. Ensures that vessel-based activities are performed in accordance with project, HGL, SIB Project Area, and regulatory requirements. Will halt work if unsafe conditions (such as weather) are observed or are anticipated.
Activity Specific Technical Leaders (e.g., engineers, geologists, regulatory specialists)	Responsible for completing technical tasks to support RD as assigned by the Senior PM.
Laboratory PM	Primary POC for laboratory communications with the RD Group. Supports field sampling efforts by providing sample containers and other supplies to the Sampling and Analysis Coordinator and ensuring that the laboratory has capacity for planned sampling events. Communicates issues relating to data quality to the Chemistry QA Manager. Refers technical and QA issues to the laboratory QA manager for resolution. Ensures that the requirements of the UFP-QAPP are transmitted to laboratory personnel supporting this project. Performs final review of laboratory data reports before delivery.
Laboratory QA Manager	Provides technical support to the laboratory PM to ensure that laboratory analyses are performed in accordance with project requirements and that the project data is technically defensible. Initiates and documents CA required to address technical concerns either raised by the Chemistry QA Manager or from internal review and reporting.
Data Validation PM	Responsible for ensuring that data validation is performed in accordance with the requirements of this UFP-QAPP, including use of project-specific data qualification conventions. Reviews or oversees the review of data validation reports prior to delivery.

CA = corrective action  
 CoC = chain of custody  
 DQO = data quality objective  
 EDD = electronic data deliverables  
 NCP = National Oil and Hazardous Substances Pollution Contingency Plan  
 POC = point of contact

## **WORKSHEET #10**

### **CONCEPTUAL SITE MODEL**

#### **10.0 INTRODUCTION**

The full conceptual site model (CSM) for PHSS is presented in the Remedial Investigation (RI)/Feasibility Study (FS) (EPA, 2016a) and ROD (EPA, 2017) for PHSS. The CSM is summarized in the Sufficiency Assessment Report (SAR) (HGL, 2021b) and the Pre-Design Investigation (PDI) Work Plan (HGL, 2021c) that have been prepared in association with this UFP-QAPP and the FSP (HGL, 2021a). The SAR presents a recontamination CSM for the SIB Project Area that provides a conceptual framework for evaluating source control sufficiency and the potential for post-remedy recontamination via upland and in-water transport pathways. A primary objective of the PDI Work Plan focuses on refinement of the site-specific application of the CSM to the SIB Project Area, including a data gap analysis, and preliminary SIB Project Area-specific CSM refinements are identified and discussed. The comprehensive refined CSM for the SIB Project Area is presented in Section 2.2 of the PDI Work Plan. This worksheet provides a summary of SIB Project Area background information but does not address the CSM presented in other documents.

The descriptions of the SIB Project Area and previous investigation and enforcement activities is summarized from the ROD (EPA, 2017), including the 2018 and 2020 errata, and the RD SOW attached to the ASAOC (EPA, 2021).

#### **10.1 DESCRIPTION**

##### **10.1.1 Portland Harbor Superfund Site**

PHSS was listed on the National Priorities List with Superfund Site Identification (ID) Number ORSFN1002155 in December 2000. The listing was mainly due to concerns about contamination in the sediments and the potential risks to human health and the environment from consuming the fish. Although PHSS includes both in-river and upland portions, the 2017 ROD describes the remedial alternatives that were considered and selects a final remedy for the in-river portion of PHSS from approximately river mile (RM) 1.9 to 11.8 and does not include actions to address the upland portion.

PHSS comprises an approximately 10-mile reach of the lower Willamette River in Portland, Multnomah County, Oregon (Figure 1-1 of the FSP), which is an urban and industrial section of the river north of, and downstream of, downtown Portland, Oregon. PHSS covers approximately 2,190 acres and extends from RM 1.9 (upriver end of the Port of Portland's Terminal 5) to RM 11.8 (near the Broadway Bridge).

While the harbor area is heavily industrialized, it is located within a region characterized by commercial, residential, recreational, and agricultural uses. Land use along the lower Willamette River in the harbor includes marine terminals, manufacturing, and other commercial operations, as well as public facilities, parks, and open spaces. In addition to industrial activities, the Willamette River and surrounding watershed historically offered access to abundant natural

resources in the river and on land. Many of these resources are still present such as fish, marine mammals, waterfowl, land mammals, and native plants.

The Willamette River is also important to many tribes. Fish are among the resources most frequently utilized by the tribes in the Portland Basin and the Willamette Valley. Culturally significant species include salmonids, lamprey (eels), eulachon (smelt), and sturgeon. Native people also fished for a variety of other resident species, including mountain whitefish, chiselmouth, northern pikeminnow, peamouth, and suckers (Butler 2004; Saleeby 1983). The harvest of the Pacific lamprey was, and continues to be, important to many tribes. Native plants were and continue to be gathered for food and medicinal purposes as well. Tribes have reserved hunting, fishing (particularly salmon and sturgeon species), and certain gathering rights through Treaties with the United States. These activities provide food for Tribal families and cultural heritage knowledge and skills. Tribal uses of these resources continue today, but access to suitable patches of habitat continues to be both a challenge and an essential element of maintaining local Tribal cultural knowledge, practices, and traditions.

### **10.1.2 The Swan Island Basin Project Area**

The SIB Project Area has been defined in the ASAO as the active cleanup area designated on Figure 31d of the ROD between approximately RM 8.1 and RM 9.2 on the northeast side of the Willamette River. SAR Figure 1-1 shows the location of the SIB Project Area within PHSS, and SAR Figure 1-2 shows a detail of the SIB Project Area and the surrounding area, including zoning and drainage features. The SIB Project Area is approximately 1.1 miles long, covers 117 acres, and includes riverbanks from the top of the bank to the river. A detailed description of the SIB Project Area physical setting is presented in Section 3.1 of the SAR. Section 3.2 of the SAR presents a detailed description of the shoreline and overwater structures within the SIB Project Area.

## **10.2 HISTORY AND ENFORCEMENT ACTIVITIES**

The following sections provide an overview of PHSS. The development history of the SIB Project Area is presented in Section 3.1.3 of the SAR. Site investigation activities at the SIB Project Area were generally conducted as a component of the PHSS-wide investigations described below. Field investigation activities specific to the SIB Project Area are discussed in Section 3.4 of the SAR.

### **10.2.1 History**

The Willamette River is the 19th largest river in the United States and is one of 14 American Heritage Rivers in the country. The Willamette River flows into the larger Columbia River, which eventually flows into the Pacific Ocean. Even though the Willamette River is nearly 100 RMs from the Pacific, there are tidal influences within the SIB Project Area and, overall, it is a large and dynamic river. During its 309-mile course, which ends at its confluence with the Columbia River, it drains 11.7 percent (%) of the area in the state of Oregon. In 1891, the Oregon State Legislature created the Port of Portland. Since the late 1800s, the Portland Harbor section of the lower Willamette River has been extensively modified to accommodate a vigorous shipping industry. Modifications include redirection and channelization of the main river; draining seasonal and permanent wetlands in the lower floodplain; and relatively frequent dredging to maintain the

navigation channel, access to docks, and wharf facilities. Constructed structures, such as wharfs, piers, floating docks, and pilings, are especially common in Portland Harbor where urbanization and industrialization are most prevalent. These structures largely accommodate or support shipping traffic within the river and stabilize the riverbanks for urban development. Riprap is the most common bank-stabilization method although upland bulkheads and rubble piles are also used. Seawalls help control periodic flooding as most of the original wetlands bordering the river in the Portland Harbor area have been filled.

Historically, contaminants from many facilities entered the river system from different activities including, but not limited to ship building and repair; ship dismantling; wood treatment and lumber milling; storage of bulk fuels; manufactured gas production; chemical manufacturing and storage; metal recycling, production, and fabrication; steel mills, smelters, and foundries; and electrical production and distribution. These activities have resulted in direct discharges from upland areas through stormwater and wastewater outfalls; releases and spills from commercial operations occurring over the water; municipal combined sewer overflows; and indirect discharges through overland flow, bank erosion, groundwater, and other nonpoint sources. In addition, contaminants from off-site sources have reached PHSS through surface water and sediment transport from upstream and through atmospheric deposition. Operations that continue today along the riverbanks include bulk fuel storage; barge building; ship repair; automobile scrapping; recycling; steel manufacturing; cement manufacturing; operation and repair of electrical transformers, including electrical substations; and many smaller industrial operations.

A federal navigation channel extends from the confluence of the lower Willamette River with the Columbia River to RM 11.6. Container and other commercial vessels regularly transit the river. Certain parts of the river require periodic maintenance dredging to keep the navigation channel at its authorized depth. In addition, the Port of Portland and other private entities periodically perform maintenance dredging to support access to dock and wharf facilities. Dredging activity has greatly altered the physical and ecological environment of the river in Portland Harbor. The current navigation depth was authorized in 1962 and dredging work on the authorized 40-foot (ft)-deep channel from Portland and Vancouver (Washington) to the Pacific was completed in 1976. In 1999, Congress authorized the Willamette River to be deepened to 43 ft; however, this has not yet occurred. Swan Island Lagoon (currently known as SIB) was created in the 1930s when dredge spoils were used to fill in part of the channel and connect Swan Island to the mainland. The federal navigation channel is located within the main river channel and does not extend into the SIB. The Willamette River channel, from the Broadway Bridge (RM 11.6) to the mouth (RM 0), varies in width from 600 to 1,900 ft. The U.S. Army Corps of Engineers maintains the navigation channel. Historical dredging activities at the SIB Project Area are discussed in Section 3.3 of the SAR.

Development of the river has resulted in major modifications to the ecological function of the lower Willamette River. However, several species of invertebrates, fish, birds, amphibians, and mammals, including some protected by the Endangered Species Act, use habitats that occur within and along the river. The river is also an important pathway for migration of anadromous fish such as salmon and lamprey. Various recreational fisheries, including salmon, bass, sturgeon, crayfish, and others, use the lower Willamette River. Resident fish in PHSS include, but are not limited to, smallmouth bass, brown bullhead, black crappie, and carp.

## **10.2.2 Historical Site Investigations**

Numerous investigations have been conducted of Portland Harbor dating back to the 1920s; however, most studies were conducted from the late 1970s through the 1990s. Some investigations were conducted on a larger scale (e.g., several RMs) while others were conducted on a smaller scale (e.g., less than 1 RM). Larger scale investigations typically were conducted by or for federal or state agencies, such as the U.S. Army Corps of Engineers, the U.S. Geological Survey, the Oregon Department of State Lands, the Oregon Department of Fish and Wildlife, the ODEQ Water Program, and EPA, to assess the river system. Smaller scale investigations typically were conducted by private parties for the purposes of maintenance dredging, construction and maintenance of in-river structures, or assessment of fate and transport of contamination from upland or in-river releases.

## **10.2.3 Preliminary Assessment and Site Investigation (1998)**

EPA conducted a Preliminary Assessment/Site Inspection of PHSS in May 1998 (Roy F. Weston, 1998). Sediment data collected during the Preliminary Assessment/Site Inspection and previous investigations resulted in the listing of PHSS on the National Priorities List.

## **10.2.4 Remedial Investigation/Feasibility Study (2001-2016)**

A group of PHSS stakeholders identified as the Lower Willamette Group (LWG) conducted an RI/FS under a series of ASAOs between LWG and EPA. The on-site component of the RI/FS included preliminary studies and three rounds of RI field investigations (EPA, 2016a). The study area investigated during RI field activities included the area of the SIB. The RI was conducted in four phases.

- Preliminary studies (non-chemical data) conducted from late 2000 to early 2002.
- Round 1 RI field investigations conducted from mid-2002 to spring 2004.
- Round 2 RI field investigations conducted from fall 2004 to spring 2006.
- Round 3 RI field investigations conducted from early 2006 through early 2008.

The preliminary studies were necessary to scope the work for conducting the RI. This phase of studies included a multi-beam bathymetric survey of the lower Willamette River (David Evans and Associates, Inc. [DEA], 2002a), a juvenile salmonid residence time survey (Ellis Ecological Services, 2002), a Sediment Trend Analysis<sup>®</sup> survey (GeoSea Consulting, 2001; Striplin Environmental Associates, Inc. [SEA], 2002a), a sediment profile imaging survey of the lower Willamette River (SEA, 2002b), and an acoustic Doppler current profiler survey conducted to measure current velocities at several transects in the river (DEA, 2002b).

Each round of RI field investigations included sampling and analysis of environmental media and the tissue of one or more species of aquatic life in the RI study area, including plants, shellfish, and fish. These conventional sampling efforts were supplemented by non-chemical testing, including geotechnical characterization, ecosystem evaluation, and cultural resource analysis.

### **10.3 ORIGINAL REMEDY**

The RI report included a comprehensive site characterization, a baseline human health risk assessment, and a baseline ecological risk assessment. The RI identified contaminants of concern (COCs) in surface water, groundwater, sediment, and biota tissue on a PHSS-wide basis and developed medium-specific cleanup levels (CULs).

#### **10.3.1 PHSS Sitewide Remedy**

The RI findings were used to produce an FS (EPA, 2016b). The FS established remedial action objectives for protection of human health and ecological protection in affected site media and evaluated multiple potential Remedial Action alternatives at PHSS. EPA issued a ROD for the in-river portion of PHSS, including the SIB, in 2017. A modification to Alternative F was chosen as the selected remedy at PHSS. The selected remedy includes a location-specific combination of sediment dredging, excavation of riverbank soil, capping, ex-situ treatment, enhanced natural recovery, and monitored natural recovery to address COCs and principal threat waste (PTW) at PHSS.

#### **10.3.2 Remedial Design at SIB**

The ROD describes a post-ROD sampling effort for PHSS to delineate and refine the Sediment Management Area (SMA) footprints, refine the CSM, determine baseline conditions, and support RD. On December 19, 2017, EPA entered into an ASAOC with the Pre-RD Agreement and Order on Consent Investigation Group to conduct the PDI and baseline sampling studies at PHSS. Additional post-ROD studies have been conducted as part of this overall PDI effort as described in Section 3.1 of the PDI Work Plan (HGL, 2021c).

## **WORKSHEET #11**

### **DATA QUALITY OBJECTIVES**

#### **11.0 DATA QUALITY OBJECTIVES**

The development of DQOs focuses on the end use of the collected data and on determining the corresponding data measurement objectives of precision, accuracy, representativeness, completeness, comparability, and sensitivity (PARCCS) necessary to satisfy the end use (see Worksheet #12). The DQO process involves seven steps designed to ensure that the type, quantity, and quality of data collected are appropriate for the intended application. Each step supports the project efforts by clarifying the project objective, defining the most appropriate type of data to be collected, and specifying acceptable levels of decision criteria. The steps are defined in *Guidance on Systematic Planning Using the Data Quality Objectives Process*, EPA QA/G4, EPA/240/B-06/001 (EPA, 2006), as follows:

- State the problem,
- Identify the goals of the project,
- Identify information inputs,
- Define the boundaries of the project,
- Develop the analytic approach,
- Specify performance or acceptance criteria, and
- Develop the plan for obtaining data.

The process is based on a framework that, through continual evaluation during project activities, allows for DQO modification as project needs change. The field activities to be conducted at the SIB Project Area under this project are based on the requirements of the PHSS ROD (EPA, 2017) and the SOW included in the ASAOC (EPA, 2021). Sampling and analysis will be performed in accordance with the project planning documents listed in Section 11.7. Table 11-1 illustrates the application of the DQO process to data collection efforts of the PDI Work Plan.

#### **11.1 STATE THE PROBLEM**

The ROD states that a post-ROD sampling effort will be conducted to support the RD, refine the CSM, and establish a baseline dataset for comparison to post-remedy conditions. The ASAOC SOW includes a data gap analysis as a component of RD, followed by additional PDI sampling to obtain chemical and geotechnical data to address the identified data gaps. This PDI study covers many elements of sampling and data collection, including sampling and analysis of surface and subsurface sediment, sediment porewater, and riverbank surface and shallow core soil; soil and sediment borings advanced to collect geotechnical samples; site characteristic measurements such as bathymetry, acoustic doppler current profiler surveys, and wave and boat wake measurements; and surveying and inspection (including by dive teams).

#### **11.2 IDENTIFY THE GOALS OF THE PROJECT**

The primary goal of this project is to complete a comprehensive RD that addresses remediation of the contamination at the SIB Project Area. To prepare the RD, interim site data evaluation and

collection activities are required to update and evaluate site conditions at the SIB Project Area to refine the CSM. The purpose of the PDI for the SIB Project Area is to:

- Determine what data and analysis are necessary to inform the RD;
- Identify and evaluate relevant, applicable and existing data and analysis;
- Identify data gaps; and
- Propose an approach to collect the data and complete the analyses required to address those data gaps and design the remedy.

The overarching objective of the PDI focuses on compiling a complete body of data and analysis to fully inform the development and evaluation of a sustainable and effective RD for the SIB Project Area. Within that primary objective, other specific objectives are used to guide the planning and implementation of the PDI to ensure this primary goal is met. Those objectives are listed below.

1. Define the specific data and analysis needs required to fully inform the design development and evaluation based on a conceptual design approach and strategy consistent with the ROD.
2. Ensure that the data and analysis needs are sufficient to support the three applications specifically required in the ASAOC for SMA refinement, CSM refinement, and effective use of the technology application decision tree (PDI Work Plan Figure 1-3).
3. Compile and evaluate existing available data and analysis relevant to the defined data and analysis needs as determined by the design and required applications.
4. Identify data gaps by comparing what is needed to what is available.
5. Develop a work plan to guide the collection of new data and the completion of new analyses to address the data gaps.

### **11.3 IDENTIFY INFORMATION INPUTS**

To achieve the goals of the SIB sediment investigation, the following information inputs will be collected in the following categories.

#### **11.3.1 Chemical Data**

Environmental sampling will include sampling surface and subsurface sediment, surface and shallow core soil, sediment elutriate, stormwater, and stormwater sediment for analysis of contaminants and target COCs in ROD Table 17, PTW in ROD Table 21, and for geotechnical analyses by ASTM methods.

#### **11.3.2 Engineering Analysis and Design Data**

Information inputs in this category will include multi-beam hydrographic and topographic survey data, geotechnical borings (on land and in water), vessel-mounted laser scan for locating and documenting locations of existing structures, and a combination of sub-bottom profiling and

magnetometer surveys for detection of debris and existing buried utilities. A dive inspection will be performed to visually inspect selected marine structures.

### **11.3.3 Numerical Modeling and Analysis**

Information inputs in this category will include multi-beam hydrographic and topographic survey data, sediment cores for SedFlume (erodibility) analysis, tidal/river current data, suspended sediment concentration data, and wind-wave and boat wake data (free surface measurements).

## **11.4 DEFINE THE BOUNDARIES OF THE PROJECT**

The SIB Project Area (Figure 1-1 of the FSP) is located on the northeastern side of the Lower Willamette River in PHSS between RM 8 and RM 9.2.

## **11.5 DEVELOP THE ANALYTIC APPROACH**

The field investigation component of the PDI will collect environmental data integral to achieving the goals of the study listed above. Data will be collected from medium-specific sampling events conducted in the SIB Project Area.

A critical component of planning for the SIB PDI is the sufficiency assessment, which will evaluate sources of contaminants to determine whether they have been adequately investigated and sufficiently controlled or considered such that the Remedial Action can proceed. The results of the sufficiency assessment have been incorporated into the data gap analysis included in the PDI Work Plan (HGL, 2021c). The project analytical methods, including target analytes and the associated laboratory sensitivity limits and the project action limits (PALs), are presented in Worksheet #15. The target analytes include the focused COCs for each site medium and those additional COCs identified on a medium-specific basis in ROD Table 17. The expansion of analyte lists beyond the focused COCs is intended to characterize contamination left in place to be addressed by remediation alternatives other than removal. Analysis for the full medium-specific analyte lists will also ensure that potential sources of off-site recontamination are addressed. The analyte lists for soil/sediment based on ROD Table 17 encompass PTW analytes identified in ROD Table 21 except chlorobenzene. This compound does not have a soil/sediment CUL and the historical data set for SIB does not include any chlorobenzene detections above the Remedial Action Level (RAL) of 320 micrograms per kilogram ( $\mu\text{g}/\text{kg}$ ) presented in ROD Table 21; therefore, this compound is not included in the project-specific analyte lists. This approach is consistent with the approach taken for a PDI performed at nearby PHSS subsite RM 9 West (Foth, 2021).

## **11.6 SPECIFY PERFORMANCE AND ACCEPTANCE CRITERIA**

The measurement performance criteria for data associated with the specific analyses include the data quality indicators (DQIs) PARCCS. To meet PARCCS requirements, QC criteria are provided in the standard field and laboratory methods. The PARCCS parameters and the associated QC samples and elements associated with them are presented below.

- Precision: Field duplicates, laboratory duplicates, laboratory control sample (LCS)/laboratory control sample duplicates (LCSD), and matrix spike (MS)/matrix spike duplicate samples (MSD).
- Accuracy (and bias): MSs, LCSs, surrogates, field and laboratory QC blanks, instrument initial calibration (ICAL), and instrument continuing calibration checks.
- Representativeness: Field sampling design, sample collection standard operating procedures (SOPs), and field and laboratory QC blanks.
- Completeness: Evaluation of the number of usable data points obtained against the number projected.
- Comparability: Use of standardized field and laboratory methods and the consistent use of field and laboratory SOPs.
- Sensitivity: Method Detection Limit (MDL) studies, instrument ICAL, and instrument sensitivity checks.

Specific objectives for each PARCCS element are established to develop sampling protocols, applicable documentation, sample handling procedures, and measurement system procedures that will be used during field activities. These are described in more detail in Worksheet #12, Worksheet #15, Worksheet #24, and Worksheet #28.

The SIB Project Area is already fully characterized, and the analytical data from this PDI will be used to fill data gaps to support RD activities. The project DQOs have been developed to address an estimation problem and determining the probability limits on decision errors is not required. Screening level analytical data with a 10% definitive data (see Section 12.3 of Worksheet #12) will be a sufficient level of data quality to support project decision-making. Geotechnical data will be of screening level. The data validation guidelines presented in Worksheet #36 reflect these performance criteria.

## **11.7 DEVELOP THE PLAN FOR OBTAINING DATA**

The PDI sampling and analysis strategy is based on the 2017 ROD and the 2021 ASAOC SOW. The basis of the sampling design and approach and sampling locations are presented in Section 4.0 of the SIB PDI Work Plan (HGL, 2021c).

**Table 11-1**  
**Summary of the 7 steps for Systematic Planning Using the DQO Process, as applied to the Swan Island Basin (SIB) Remedial Design (RD)**

Step	Mobile LiDAR	Bathymetry	Side-scan Sonar	Magnetometer	Sub-bottom Profiling	Geotechnical Sampling	Chemistry Sampling	Current Profiling	SedFlume Sampling	
1	State the problem	RD requires knowledge of exposed debris, marine structure locations, and riverbank elevations in SIB.	RD requires accurate depth information in the river and SIB.	RD requires identification of debris and/or utilities that could pose a hazard during dredging or capping.	RD requires identification of ferrous material both above and below the mudline that could pose a hazard during any dredging or capping activity, including UXOs.	RD requires geological information and identification of buried debris that could pose a hazard during dredging or capping.	RD requires soil engineering properties for analysis of riverbank stability, cap stability, functional structures evaluation, and design.	RD requires current velocity and direction data to understand SIB dynamics and calibrate/validate numerical models.	RD requires soil erodibility properties for analysis of sediment resuspension and scour as part of recontamination studies.	
2	Identify the goals of the study	Estimate locations of emergent debris, marine structures and riverbank elevations.	Estimate submerged riverbed elevations.	Identify underwater debris and estimate its location to evaluate whether it requires removal as part of Remedial Action (RA) and provide data to help interpret bathymetry data gaps.	Identify ferrous material both above and below the mudline and estimate their locations to determine whether they affect RA.	Illustrate geological formations, identify the presence of buried debris/utilities, and estimate their locations to determine whether they affect RA.	Identify and characterize the types of soil present at the site, develop estimates of geotechnical engineering design parameters, identify geotechnical hazards, and assess overall ground conditions.	Estimate site sediment COC concentrations by targeting surface and subsurface data gaps.	Estimate speed and direction of currents in the river and in SIB.	Estimate soil erodibility and density properties for use in resuspension and scour analysis.
3	Identify information inputs	New locations and elevations of marine structures, emergent debris, and riverbank elevations are needed. Inputs to surveyors include focus areas, overlap with bathymetry data by covering lowest possible areas on profile. Survey accuracy goal prescribed to surveyor is positioning to 2-3cm accuracy to the extent feasible, with data sampling rate of 200 Hz within 300 feet scanning range.	New submerged riverbed elevations are needed. Inputs to surveyors include covering best available upper riverbank area, and coverage as complete as possible considering unavoidable obstructions. Survey accuracy goal prescribed to surveyor is best feasible based on field conditions, at sampling frequency 400 kHz within 200m operational range.	New imaging of locations of in-water debris is needed. Position and object detection location accuracy goal prescribed to surveyor is best possible based on field conditions, and detection of objects down to 0.45m in size at maximum 100m range. Complete nearshore coverage is prescribed to the extent feasible based on obstructions encountered in the field.	New locations of ferrous objects are needed. Object detection accuracy goal prescribed to surveyor is best possible based on field conditions, towing magnetometer at least 2.5 vessel lengths behind vessel, at 7m above riverbed. Surveyor to survey initial site-wide transects, identify targets for further identification, and run localized transects around detections.	New imaging of locations of geological strata and buried objects is needed. Sub-bottom geology/object detection accuracy goal prescribed to surveyor is best possible penetration based on field conditions, up to 25m for detailed stratification at layer resolution 5cm. Surveyor to survey initial site-wide transects, identify targets for further identification, and run localized transects around detections.	New soil engineering properties are needed. Inputs to the geotechnical sampling program include soil borings, cone penetration tests, shear wave velocity tests, pore pressure dissipation testing, and PS-wave suspension logging at select locations. Additional information regarding the geotechnical sampling information inputs is included in Section 4.4 of the Field Sampling Plan and in the PDI Work Plan.	New surface and subsurface sediment concentration samples are needed. Inputs to the sediment chemistry sampling include surface grab samples targeting the top 30cm of sediment and subsurface cores targeting 1-foot intervals from the sediment surface to 10- to 20-feet, and the laboratory analyses performed on those samples.	New measurements of current speed and direction is needed, using typical industry performance criteria, and typical industry sampling and analysis methods are deemed appropriate.	New soil erodibility properties are needed. Inputs to SedFlume field core collection and laboratory analysis consist of only locations to be sampled. Sampling crew will sample cores up to 30cm typical surface sediments at 30 distinct locations. Laboratory methods are standardized as developed by subcontractor.
4	Define the boundaries of the study	SIB areas with riverbanks and marine structures potentially affected by RA. See Figure 5-3 of the Field Sampling Plan.	SIB site-wide riverbed areas and nearby Lower Willamette River riverbed areas near areas to undergo RA. See Figure 5-1 of the Field Sampling Plan.	SIB site-wide areas with submerged debris, riverbanks, and marine structures potentially affected by RA. See Figure 5-2 of the Field Sampling Plan.	SIB site-wide riverbed areas potentially affected by RA. See Figure 5-2 of the Field Sampling Plan.	SIB riverbed areas potentially affected by RA. See Figure 5-2 of the Field Sampling Plan.	SIB site-wide riverbed and upland areas potentially affected by RA. See Figure 4-7 of the Field Sampling Plan.	SIB site-wide riverbed areas potentially affected by RA. See Figures 4-3 and 4-4 of the Field Sampling Plan.	SIB water body and nearby Lower Willamette River water body areas that control water and sediment movements to SIB. See Appendix A.	SIB site-wide riverbed areas potentially affected by RA. See Figure 5-4 of the Field Sampling Plan.

**Table 11-1 (Continued)**  
**Summary of the 7 steps for Systematic Planning Using the DQO Process, as applied to the Swan Island Basin (SIB) Remedial Design (RD)**

Step	Mobile LiDAR	Bathymetry	Side-scan Sonar	Magnetometer	Sub-bottom Profiling	Geotechnical Sampling	Chemistry Sampling	Current Profiling	SedFlume Sampling	
5	Develop the analytical approach	Parameter of interest is point cloud location data; methodologies already exist for data collection (see Sections 2.5 and 2.6 of Appendix A).	Parameter of interest is elevation data; methodologies already exist for data collection (see Sections 2.7 and 2.8 of Appendix A).	Parameter of interest is identification of objects; methodologies already exist for data collection (see Sections 3 and 3.1 of Appendix A).	Parameter of interest is identification of ferrous objects; methodologies already exist for data collection (see Sections 4 and 4.1 of Appendix A).	Parameter of interest is identification of geological patterns and objects; methodologies already exist for data collection (see Sections 5 and 5.1 of Appendix A).	Parameters of interest are engineering soil properties. Methodologies for drilling, sampling, and testing already exist (see Section 4.4 of the Field Sampling Plan).	Parameters of interest are soil chemistry including contaminants of concern. Methodologies for drilling, sampling, and testing already exist (see Section 4.2 of the Field Sampling Plan).	Parameter of interest is identification of speed and direction of water movement; methodologies already exist for data collection.	Parameters of interest are soil erodibility properties (critical shear stress for erosion, erosion rate) and density properties. Methodologies for collection and laboratory analysis already exist (see Section 5.4 of the Field Sampling Plan).
6	Specify performance or acceptance criteria	Performance goals include overlap with bathymetry data to the extent feasible in the field, as well as structure/debris identification. Best available position accuracy described in Appendix A, Sections 2.5 and 2.6, are suitable for reliable use.	Performance criteria including achieving best available position accuracy and data returns based on equipment described in Appendix A, Sections 2.7 and 2.8, are suitable for reliable use.	Performance criteria including achieving best available position accuracy and data returns based on equipment described in Appendix A, Sections 3 and 3.1, are suitable for reliable use.	Performance criteria including achieving best available position accuracy and ferrous material data returns based on equipment described in Appendix A, Sections 4 and 4.1, are suitable for reliable use.	Performance criteria including achieving best available position accuracy and geological data pattern returns based on equipment described in Appendix A, Sections 5 and 5.1, are suitable for reliable use.	Performance criteria include achieving best estimate of soil properties are described in the applicable ASTM standards and guidance documents described in Section 4.4 of the Field Sampling Plan. Additionally, geotechnical sampling will be performed under the observation and direction of an engineer/geologist.	Performance criteria include achieving best estimates of soil chemistry according to field methodology and standards used for laboratory testing described in Section 4.2 of the Field Sampling Plan.	Standard industry accuracy tolerances described in Appendix A are suitable for reliable use.	Performance criteria include achieving best estimate of soil erodibility and density properties according to subcontractor standard methodology (see Section 5.4 of the Field Sampling Plan). Typical laboratory reporting by subcontractor is suitable for use.
7	Develop the plan for obtaining data	Plan for locations is shown in Figure 5-3 of the Field Sampling Plan, and methodology for collection is described in Appendix A Sections 2.5 and 2.6.	Plan for locations is shown in Figure 5-1 of the Field Sampling Plan, and methodology for collection described in Appendix A Sections 2.7 and 2.8.	Plan for locations is shown in Figure 5-2 of the Field Sampling Plan, and methodology for collection is described in Appendix A Sections 3 and 3.1.	Plan for locations is shown in Figure 5-2 of the Field Sampling Plan, and methodology for collection is described in Appendix A Sections 4 and 4.1.	Plan for locations is shown in Figure 5-2 of the Field Sampling Plan, and methodology for collection is described in Appendix A Sections 5 and 5.1.	Plan for locations is shown in Figure 4-7 of the Field Sampling Plan, and methodology for collection is described in Section 4.4 of the Field Sampling Plan).	Plan for locations is shown in Figures 4-3 and 4-4 of the Field Sampling Plan, and methodology for collection is described in Section 4.2.	Standard industry approach to data collection is preferred. See Appendix A for additional details.	Plan for locations is shown in Figure 5-4 of the Field Sampling Plan. Methodology for data collection is described in Section 5.4 of the Field Sampling Plan.

**WORKSHEET #12**  
**METHOD MEASUREMENT PERFORMANCE CRITERIA TABLES**

**12.0 MEASUREMENT PERFORMANCE CRITERIA**

The overall QC objective for this project is to develop and implement procedures for sample collection, laboratory analysis, field measurement, and data reporting that will provide data of a degree of quality consistent with its intended use as described in the DQO process (Worksheet #11). Worksheet #12 and the associated method-specific worksheets present the performance criteria for the analytical measurements performed in support of this project. The project analytical methods are primarily from EPA’s SW-846 methods compendium (EPA, 2015) unless otherwise noted.

**12.1 DATA QUALITY INDICATORS**

Of the six PARCCS DQIs, precision, accuracy, completeness, and sensitivity can be quantitatively measured and assessed. The parameters of comparability and representativeness are primarily qualitative in nature.

**12.1.1 Quantitative Data Quality Indicators**

Quantitative DQIs can be measured and assessed by performing QC checks and evaluating the results against numerical acceptance criteria. For this project, method-specified control limits will be used; where the method does not specify control limits, QC checks will be evaluated against the laboratory’s internally generated control limits for routine analyses. These QC limits will be sufficient to ensure that the analytical methods are performed under acceptable conditions and that results can be used as reported for the intended purposes following the data validation and quality evaluation processes, as described in Worksheet #36 and Worksheet #37.

**12.1.1.1 Precision**

Precision is the measure of variability between individual sample measurements under prescribed conditions. Precision can be assessed by replicate measurements of known laboratory standards and by analysis of duplicate environmental samples (spiked or unspiked). Precision is determined by evaluating the relative percent difference (RPD) between duplicate sample results. Replicate measurements of known standards (LCS/LCSD pairs), spiked samples (MS/MSD pairs), and laboratory duplicate analyses are routinely monitored by the laboratory by comparing the RPD with established control limits. The formula for calculating RPD is as follows:

$$RPD = \frac{|S - D|}{\frac{(S + D)}{2}} \times 100$$

where:

- S = first sample value (original sample, LCS, or MS value); and
- D = second sample value (duplicate sample, LCSD, or MSD value).

The overall precision of measurement data is affected by both sampling and analytical factors. Analytical precision is much easier to control and quantify than sampling precision; there is more historical data related to individual method performance, and the “universe” is not limited to the samples received in an individual laboratory. In contrast, sampling precision is unique to the project. Sampling precision will be measured through the laboratory analysis of field duplicate samples. For field duplicates, homogenized samples will be split into two samples for analysis to assess sample homogenization and matrix heterogeneity variability. Laboratory precision will be measured through the analysis of MS/MSD pairs, LCS/LCSD pairs, and laboratory duplicate pairs.

### 12.1.1.2 Accuracy

Accuracy is the degree of agreement of a measurement to an accepted reference or true value. An evaluation of the accuracy of a measurement system provides an estimate of measurement bias. Overall analytical accuracy is assessed on a batch-specific basis by evaluating the percent recovery (%R) of known concentrations for each analyte in the LCS (and LCSD) against the QC limits. One known reference standard or LCS is analyzed for every batch (maximum of 20 samples). The accuracy of specific sample analyses is assessed by evaluating the %R of the surrogate spike compounds (organic analyses). The %R QC criteria for MS/MSDs will be used to assess the potential for matrix interferences. The formula for calculating %R is as follows:

$$\%R = \frac{A - B}{C} \times 100$$

where:

- A = the analyte concentration determined experimentally from the spiked sample;
- B = the background level determined by a separate analysis of the unspiked sample (for calibration standards, LCSs, and surrogate compounds, the value of this term is zero); and
- C = the amount of the spike added.

Accuracy is also measured using percent difference (%D) between a result and the expected value. The %D is usually used to evaluate accuracy when the acceptance of a QC result is dependent on another analytical result and not on a pre-defined window of acceptance, such as evaluation of continuing calibration verification (CCV) standard performance against the results of the corresponding ICAL. The formula for calculating %D is as follows:

$$\%D = \frac{A - B}{A} \times 100$$

where:

- A = the original quantity measured, and
- B = the comparison quantity measured.

The accuracy of an individual data point can be affected by random fluctuations within the sampling and analysis system. Accuracy can also be affected by systematic factors due to sampling, the properties of the sampled matrix, the properties of the target analyte, and analytical system problems.

There are three broad categories of mechanisms by which bias can be introduced into analytical results, which can be monitored by the sampling and analysis QC procedures.

- High bias, which can stem from cross-contamination of sampling, packaging, or analytical equipment and materials. Cross-contamination is monitored through blank samples, such as equipment blanks (EBs), field blanks, trip blanks (TBs), and method blanks (MBs). These samples assess the potential for cross-contamination from, respectively, sampling equipment, ambient conditions, packaging and shipping procedures, and laboratory equipment. Data validation protocols provide a structured protocol for data qualification based on blank contamination.
- Low bias, which can stem from the dispersion and degradation of target analytes. The effects of these mechanisms are difficult to quantify. Sampling accuracy can be maximized, however, by the adoption and adherence to a strict field QA program. Specifically, sampling procedures will be performed following the standard protocols described in the FSP (HGL, 2021a). Appropriate sample containers, physical and chemical sample preservation, and holding times for preparation and analysis have been established to address potential analyte losses due to analyte loss or degradation. Through regular review of field procedures, deficiencies will be documented and corrected in a timely manner.
- High or low bias, as indicated by %R discrepancies, can occur due to calibration issues, system control problems, sample preparation issues, and challenging sample matrices. Analytical accuracy in the laboratory will be determined through the analysis of surrogates, LCSs, and MS/MSDs. As with blank samples, data validation protocols provide a structured protocol for data qualification based on high or low analyte recoveries outside of the acceptance limits.

### 12.1.1.3 Completeness

Completeness is a measure of the amount of valid data obtained compared with the amount that was expected to be obtained under correct, normal conditions. It is calculated for the aggregation of data measured for sampling events or other defined set of samples. Valid data is data that is usable in the context of the project goals and DQOs. Completeness is calculated and reported for each method, matrix, and analyte combination. The number of valid results divided by the number of possible individual analyte results, expressed as a percentage, determines the completeness of the dataset.

Sampling completeness is defined as the percentage of analytical results obtained compared with the projected number of analytical results that would be obtained from planned sample locations. Analytical completeness is defined as the percentage of valid (nonrejected) analytical results obtained from measurement systems compared with the total number of analytical results requested. The formula for calculating sampling completeness is as follows:

$$\text{Sampling Completeness} = \frac{\text{Number of Data Points Obtained}}{\text{Number of Planned Data Points}} \times 100\%$$

The formula for calculating analytical completeness is as follows:

$$\text{Analytical Completeness} = \frac{\text{Number of Acceptable Laboratory Measurements}}{\text{Number of Laboratory Measurements Reported}} \times 100\%$$

The overall completeness for each aspect of this project is defined as the sampling completeness multiplied by the laboratory completeness. Although the ideal of 100% data completeness may not be achieved for a dataset, that dataset may still be usable to make project-specific decisions. The impact of rejected or missing data on project decisions will be evaluated on a case-by-case basis in accordance with Worksheet #37. In addition to calculating overall completeness for project datasets, completeness can be evaluated as subsets of the overall dataset, including subsets selected by method, matrix, or analyte. Completeness will generally be calculated on a task-specific and project-specific basis.

Completeness is calculated at the end of the data validation process and generally is not used to evaluate an ongoing data generation process. However, the potential impact on completeness is one of the deciding factors in determining the appropriate course of CA when sample results are affected by a QA discrepancy.

#### **12.1.1.4 Sensitivity**

Sensitivity is defined as the capability of a method or instrument to discriminate between measurement responses representing different levels of a variable of interest.

The MDL is the smallest analyte concentration that can be demonstrated to be different from zero or a blank concentration at the 99% level of confidence. At the MDL, the false positive rate (Type I error) is 1%. MDLs are specific to an individual determination performed at an individual laboratory.

The estimated detection limit (EDL) is similar to the MDL, but instead of being calculated across all laboratory instruments based on spiking studies using statistical methods, the EDL for target analytes is calculated on a sample-specific basis using the quantified instrument noise in each sample analysis. The reporting of non-detected results at the EDL as an alternative to the use of the MDL (see below) is limited to analyses performed by high-resolution gas chromatography/high-resolution mass spectrometry (HRGC/HRMS).

The practical quantitation limit (PQL), also known as the reporting limit, is the lowest concentration that produces a quantitative result within specified limits of precision and bias. The PQL for each analyte should be set at or above the concentration of the lowest ICAL standard.

Detected analytical results with quantitation at or above the MDL, but below the PQL, will be reported as detections by the laboratory with the qualification “J.” Detected analytical results at or above the PQL will be reported without qualification unless affected by a QC issue. To maintain comparability with data reporting conventions used in previous SIB Project Area investigations, non-detected results or results with concentrations below the associated MDL, will be reported by the laboratory as the MDL with the qualification “U.” Alternative reporting formats for non-detections are acceptable if the result is clearly identified as a non-detection and the MDL is

presented on the data reporting page. The laboratory MDLs and PQLs are determined in clean matrices under controlled conditions that may not be entirely reproducible with environmental samples. On a sample-specific basis, the analyte MDLs and PQLs are modified to account for dilution (to address high analyte concentration or matrix interference), subsample size that differs from the nominal subsample size, and percent moisture of solid samples. These sample-specific adjusted MDLs and PQLs are the sensitivity limits that should be reported by the laboratory in association with analytical results.

Analytical sensitivity is evaluated by comparing method PQLs and MDLs to PALs. ROD Table 17 (including Errata #1 and #2) establishes the PALs for the SIB Study Area COCs and ROD Table 21 (including Errata #1) establishes the PALs for the SIB Study Area PTW. Analytical sensitivity limits are compared to the PALs for project analytes in the method-specific Worksheet #15 tables.

### **12.1.2 Qualitative Data Quality Indicators**

The DQIs of representativeness and comparability have only a limited ability to be evaluated using QC analysis results. These DQIs are primarily controlled by project planning and execution. This project-specific UFP-QAPP addresses the performance requirements for these DQIs based on the existing SIB Project Area data and conditions.

#### **12.1.2.1 Representativeness**

Representativeness is the degree to which data accurately and precisely expresses a characteristic of a population, parameter variations at a sampling point, or an environmental condition. Although representativeness is a qualitative measurement, it is evaluated through a multi-step process beginning with evaluation of precision and accuracy data. Project design is one of the critical inputs that determine if the data collected is representative of the population sampled. Representativeness is ensured by collecting enough samples of an environmental medium, properly chosen with respect to place and time. The precision of a representative set of samples reflects the degree of variability of the sampled medium as well as the effectiveness of the sampling techniques and laboratory analysis.

Representativeness of individual samples will be controlled by sample collection and handling in accordance with the requirements of Worksheets #14/#16 and the SOPs presented Appendix A of the FSP. The sample containers and preservation methods presented in Worksheets #19/#30 will be used to ensure that samples arriving at the laboratory retain the appropriate degree of representativeness. The holding times presented in Worksheets #19/#30 have been established to ensure that samples retain representativeness at the time of extraction and analysis.

Representativeness also will be assessed using field and laboratory blank samples. An MB will be analyzed with every analytical or preparation batch (as appropriate to the analytical method) to determine potential contamination introduced during routine laboratory procedures. Initial calibration blanks (ICBs) and continuing calibration blanks (CCBs) will be analyzed as required by analytical methods. TBs and EBs will be collected to assess potential contamination due to field conditions. The assessment of blank samples will determine if compounds detected in the environmental samples are site-related or have been introduced through shipping, storage, field procedures, or laboratory procedures.

### **12.1.2.2 Comparability**

Comparability expresses the confidence with which one dataset can be compared to another. Comparability also involves a multi-step evaluation and can be related to accuracy and precision as these quantities are measures of data reliability, as well as to sensitivity limits (MDL and PQL) for analytical methods. Data is comparable if site considerations, collection techniques, as well as measurement procedures, methods, and sensitivity limits are equivalent for the samples within a sample set.

For this project, sample collection is intended to fill data gaps or otherwise extend an existing dataset and comparability of analytical results from this PDI with results in the historical dataset is of great importance. Where possible, analytical methods used in previous sampling events will be used to support this PDI, and the analyses will be performed by the same project laboratories that have supported previous SIB Project Area sampling events. These laboratories are experienced in analyzing samples from SIB Project Area matrices and the project-specific data reporting requirements.

## **12.2 ELEMENTS OF QUALITY CONTROL**

A QC system is a set of internal procedures used by the field team and laboratory for assuring that the data output of a measurement system meets prescribed criteria for data quality. A well-designed internal QC program must be capable of controlling and measuring the quality of the data in terms of precision and accuracy. This section addresses QC procedures associated with field sampling and analytical efforts. Included are general QC considerations as well as specific QC checks that provide ongoing control and assessment of data quality in terms of precision and accuracy.

### **12.2.1 Field Quality Control**

Field QC samples are collected in the field and used to evaluate the validity of the field sampling effort. Field QC samples are collected for laboratory analysis to check sampling and analytical precision, accuracy, and representativeness. The following section discusses the types and purpose of field QC samples that will be collected for this project. The frequency of collection and approximate number of field QC samples is presented in Worksheet #20.

#### **12.2.1.1 Field Duplicates**

Field duplicates are additional samples collected at a sampling location from the bowl or container of field-composite material and then split into two unique samples to enable statistical analysis of the resulting data. Two sets of samples from a single source are prepared, labeled with unique sample numbers, and submitted to the laboratory.

#### **12.2.1.2 Equipment Blanks**

EBs are used to assess the introduction of chemical contaminants during sampling and field processing activities and to help determine if decontamination procedures are effective at removing contaminated material from non-dedicated sampling equipment. EBs will consist of rinsate blanks collected by pouring de-ionized water over or through decontaminated sampling equipment and collected in the appropriate sample containers. These samples will be analyzed

along with the associated field samples. EBs are not required to be collected from disposable field equipment or equipment dedicated to a single location (such as a dedicated groundwater monitoring pump). Field equipment rinsate blanks will be generated for all chemical parameter groups, with 1 EB being collected for every 20 analytical samples and submitted for analysis to the laboratory for the same constituents targeted in that day's sampling. The results of the analyses of these QC sample types will be used as independent, external checks on laboratory and field contamination sources.

### **12.2.2 Analytical Laboratory Quality Control**

The analytical laboratories QC procedures will be consistent with the requirements of the analytical methods and the laboratories SOPs (Worksheet #23 and Appendix A). The laboratory PMs will oversee the activities of analytical chemistry support staff employed on this project. Oversight will be achieved through on-site audits and reviews of analytical facilities prior to and during analysis of project samples (see Worksheet #31, #32, and #33). The frequencies of analytical QC samples and associated CA for discrepancies are shown in Worksheet #28.

Analytical laboratory QC samples are used to evaluate PARCCS parameters for the analytical results (Table 5). Analytical methods specify routine procedures that are required to evaluate whether data is within proper QC limits. Additional internal QC includes collection and analysis of field and laboratory QC samples, as described in the sections that follow.

#### **12.2.2.1 Method Blanks**

MBs are used to check for laboratory contamination and instrument bias. A method (or preparation) blank is prepared at the frequency specified by the referenced method, typically one per preparation batch (a preparation batch is defined as a group of samples prepared together within a 24-hour time frame, not to exceed 20 samples). An MB is prepared and processed using the same procedures and reagents as are used to prepare the field samples in the associated batch. The purpose of the MB is to ensure that contaminants are not introduced by the laboratory bottle ware, reagents, standards, personnel, or the sample preparation environment.

Some analytical methods (such as metals) require additional blanks to be analyzed before, during, and after the analytical sequence. These ICBs and CCBs are aliquots of laboratory-grade water injected into the instrument without preparation. ICBs/CCBs are used to verify and monitor the stability of the analytical system and are also used to ensure that samples with high analyte concentrations have not contaminated the analytical system.

#### **12.2.2.2 Matrix Spikes and Matrix Spike Duplicates**

MS/MSD duplicate pairs provide information to assess precision and accuracy. The MS is a replicate of an environmental sample to which known concentrations of target analytes have been added. The MS is carried through the entire analytical procedure, and the recovery of the analytes, expressed as %R, is calculated by comparison to the expected recovery (see Section 12.1.1.2). The MS is used to evaluate the effect of the sample matrix on the accuracy of the analysis. The MSD is a second replicate of an environmental sample that is also spiked with known concentrations of the same analytes used for the MS; the target analyte %Rs in the MSD are evaluated in the same

manner as for the MS. The recovered concentrations in the two spiked replicates are also compared to determine the effects of the matrix on the precision of the analysis, expressed as RPD (see Section 12.1.1.1). When an analytical method is expected to produce positive results for most analytes (such as metals in soil), it is acceptable for the laboratory to perform an MS only and use a laboratory duplicate to assess precision.

Although MS/MSD analyses are laboratory QC, additional sample volume is required to perform these QC checks and the expected number of MS/MSD pairs is also included in the summary of field QC samples presented in Worksheet #20.

#### **12.2.2.3 Laboratory Control Sample**

LCSs are used to monitor the laboratory's day-to-day performance of routine analytical methods independent of matrix effects and are prepared at a frequency of one per preparation batch. LCSs are spiked at known concentrations using standard solutions containing target parameters of interest (or a method-defined subset of parameters). The %R of these standards is quantitatively measured during analysis. Although not required, in practice laboratories may include an LCSD in an analytical batch. The %R for each LCSD is evaluated in the same manner as for LCSs, and the results of the LCS and LCSD are compared as a batch-specific evaluation of precision. Some methods utilize pre-defined acceptance criteria for evaluating LCS (and LCSD) %R; however, some methods use laboratory historical records to evaluate LCS performance and use statistical evaluation to establish laboratory-specific control limits.

#### **12.2.2.4 Surrogate Spikes**

Surrogate spike analyses provide information on a laboratory's ability to recover the analytes of interest. As required by the method, each sample, blank, QC sample, and standard is spiked with one or more surrogate compounds. These compounds are often deuterated, fluorinated, or brominated compounds that are unlikely to be found in the environment but have extraction and analytical properties similar to the target compounds for that method. The surrogate spike is added prior to sample preparation steps (except volatile organic compounds [VOCs] surrogates, which are added after sample dilution) and carried through the entire analytical procedure. Results are expressed as %R for each surrogate. Discrepancies in surrogate %Rs can be indicative of sample-specific matrix effects or more general analytical issues.

#### **12.2.2.5 Certified Reference Material**

Each laboratory will analyze certified reference materials (CRM) per analysis per matrix, if available, at a frequency of at least once at the beginning of each project task that has an analytical component. Otherwise, analysis of CRMs will be per the requirements of the analytical method and laboratory QA program as applicable. The CRM results will be assessed against the acceptance criteria provided by the CRM vendor.

#### **12.2.2.6 Method-Specific QC Requirements**

There are QC requirements that are applicable on a method-specific basis, such as internal standards for analysis for gas chromatography/mass spectrometry (GC/MS) methods or serial dilutions for metals analysis methods. Method-specific QC elements that are associated with

calibration or instrument setup and the associated CA for discrepancies are presented in Worksheet #24. Method-specific QC analyses associated with laboratory batches or individual sample analyses are presented in the method-specific Worksheet #12 tables, with associated CA requirements presented in Worksheet #28.

### **12.3 DATA QUALITY CATEGORIES**

There are two general categories of data that will be generated for use in project decision-making: (1) screening data and (2) definitive data. The data validation requirements for each matrix and analytical parameter and matrix are specific to each project data source and end use. These requirements are summarized in Section 11.6 of Worksheet #11. The full process is described in Worksheet #36. The data usability evaluation procedures are summarized in Worksheet #37.

#### **12.3.1 Screening Data**

Screening data is generated by rapid methods of analysis with less rigorous sample preparation, calibration, or QC requirements than are necessary to produce definitive data. Sample preparation steps may be restricted to simple procedures such as dilution with a solvent instead of elaborate extraction/digestion and cleanup. Screening data may provide analyte identification and quantitation, although the quantitation may be relatively imprecise. Screening data may be considered of unknown quality without corresponding definitive confirmation data. Several screening methods identified for use in this project have no corresponding definitive method and results from these methods will not require confirmation.

Some methods that routinely produce definitive data also can produce screening level data if the data validation process is not performed or is reduced. This does not necessarily indicate a lower level of data quality; it is an indication of the usability of the affected results. This reduced level of data validation will depend on the end use of the data and this determination is made on a project-specific basis. The analytical methods that will only be required to produce screening level data and the associated sample matrices are indicated in Worksheet #11, Worksheet #23, and Worksheet #36. For this project, data that is of screening level quality will either receive a data verification corresponding to Stage 1 validation or validation that includes only these screening level elements that correspond to Stage 2A data review. These stages are defined by EPA in *Guidance for Labeling Externally Validated Laboratory Analytical Data for Superfund Use* (EPA, 2009). Use of data without or with reduced validation does not relieve these laboratories from conducting analyses in accordance with internal SOPs, method requirements, project requirements, and good overall analytical and professional practices.

#### **12.3.2 Definitive Data**

Definitive data is generated using rigorous analytical methods, such as approved EPA reference methods. The data can be generated in a mobile or fixed-base laboratory. Definitive data is analyte-specific, and both identification and quantitation are confirmed for each analyte. Definitive analytical methods have standardized QC and documentation requirements and produce data for which analytical error (bias) can be determined. For data to be classified as definitive, the data must be validated after the results are reported to verify that the appropriate QC measures were taken and were in control. Also, the sample must be collected in a manner that is representative of

current site conditions, as described in the field SOPs (Worksheet #21 and FSP Appendix A). Definitive data is not restricted in its use unless quality problems identified in the validation process require data qualification. The analytical methods that will be required to produce definitive level data are indicated in Worksheet #11, Worksheet #23, and Worksheet #36. For data to be considered definitive, it must undergo validation that corresponds to Stage 2B, Stage 3, or Stage 4 data review as defined by *Guidance for Labeling Externally Validated Laboratory Analytical Data for Superfund Use* (EPA, 2009).

## **12.4 MEASUREMENT PERFORMANCE CRITERIA TABLES**

The data quality elements presented in the Worksheet #12 tables include data quality elements associated with one or more of the DQIs discussed in Section 12.1 and specific QC samples and analyses discussed in Section 12.2. The acceptance criteria presented in Worksheet #12 tables are linked to the data validation protocols. Each project laboratory is required to ensure compliance with method and SOP requirements regardless of the level of data validation that will be performed on the resulting data (see Worksheet #36). If a QC element does not meet control criteria and CA was not performed or was not effective, the appropriate qualifier will be applied to associated results during the data validation process. The overall impact of QC discrepancies, including data gaps resulting from rejected data points, will be assessed in accordance with Worksheet #37.

### **12.4.1 Blank Evaluation**

It should be noted that the Worksheet #12 tables present acceptance criteria for reporting data associated with low levels of blank contamination. It is acceptable for the laboratory to report analytical data with low levels of blank contamination meeting the Worksheet #12 acceptance criteria. However, during the data validation process, *all* detected values in blanks will be used to evaluate the associated sample data, *regardless of whether the reported blank results met the acceptance criteria presented in Worksheet #12*. This is the one of the few cases where QC data that meets *reporting* acceptance requirements may still result in qualification of the associated data.

### **12.4.2 Laboratory SOPs**

The Worksheet #12 worksheets identify the analytical methods using the reference identification used by EPA or other method source. Worksheet #23 identifies the project laboratory's SOPs for performing these methods by title, date, and revision. SOPs identified in Worksheet #23 are considered business confidential and can be produced if requested.

## WORKSHEET #12.1A

### MEASUREMENT PERFORMANCE CRITERIA: VOLATILE ORGANIC COMPOUNDS, SEMIVOLATILE ORGANIC COMPOUNDS, AND POLYCYCLIC AROMATIC HYDROCARBONS

Matrix: Solid (SVOCs and PAHs) and aqueous (VOCs, SVOCs, and PAHs)

Analytical Group/Method: GC/MS / SW-846 Methods 8260C (VOCs); 8270D (SVOCs); 8270-SIM (PAHs)

Concentration Level: Trace (VOCs); Low (SVOCs; PAHs in solids); Ultra-Low (PAHs in aqueous matrices)

DQI	QC Sample or Measurement Performance Activity	Measurement Performance Criteria
Precision (overall)	Field Duplicate	RPD $\leq 50\%$ (solid matrix) or $\leq 30\%$ (aqueous matrix) if both results $\geq 5x$ PQL <sup>1</sup>
Precision (analytical)	LCS/LCSD <sup>2</sup>	RPD limits presented in Worksheet #12.1b (VOCs), Worksheet #12.1c (SVOCs), and Worksheet #12.1d (PAHs)
Precision (analytical, matrix interference)	MS/MSD	
Accuracy (analytical)	LCS and LCSD <sup>2</sup>	%R limits presented in Worksheet #12.1b (VOCs), Worksheet #12.1c (SVOCs), and Worksheet #12.1d (PAHs)
Accuracy (analytical, matrix interference)	MS and MSD	
Accuracy (analytical, matrix interference)	Surrogate Spike	
Representativeness (field)	EB (Rinse)	Not detected > PQL
Representativeness (transport)	Temperature Blank	0°C to 6°C
Representativeness (analytical system)	Laboratory MB	No analytes detected > 1/2 the PQL
Sensitivity	MDL and PQL	Adjusted correctly for sample-specific factors (subsample size, moisture content, dilution)
Completeness	Calculation of field and analytical completeness	>90% completeness
Accuracy (analytical, matrix interference)	Internal standards <sup>3</sup>	Peak area within 50-200% of peak area in corresponding mid-point ICAL standard or CCV standard on days when ICAL is not performed.
		Peak retention time within $\pm 30$ seconds of peak retention time in corresponding mid-point ICAL standard or CCV standard on days when ICAL is not performed.
Sensitivity	MDL	MDL at or below the analyte-specific PALs listed in Worksheets #15.1, #15.2a and b, and #15.3a and b.
		Conducted and updated at least annually <sup>3</sup>
Sensitivity	PQL <sup>3</sup>	Established at or above the low point of calibration curve

<sup>1</sup> For low-level results (one or both detected values  $\leq 5x$  PQL) or when one result is a non-detection, the control limit is absolute difference  $\leq 2x$  PQL (solid matrix) or  $\leq$  PQL (aqueous matrix). Non-detected values will be assigned the nominal value of the MDL for making this comparison.

<sup>2</sup> LCSDs are not a method requirement; however, if LCSD results are reported, the LCSD%Rs and LCS/LCSD RPD will be evaluated.

<sup>3</sup> This method requirement will only be reviewed to complete definitive (Stage 4) data validation.

<sup>1</sup> Both the SIM and the ultra-low level (ULL) modification to SIM are presented in ALS-Kelso SOP SVM-8270S (see Worksheet #23); solid matrix samples will be analyzed by the standard 8270-SIM procedures and aqueous matrix samples will be analyzed using the ULL modification presented in the SOP.

## WORKSHEET #12.2A

### MEASUREMENT PERFORMANCE CRITERIA: PCBs AS AROCLORS, HERBICIDES, AND TRIBUTYLTIN

Matrix: Solid (PCBs and tributyltin) and aqueous (PCBs, herbicides, and tributyltin)

Analytical Group/Method: GC/ECD / SW-846 Methods 8082A and 8151A; GC/FPD / Laboratory-developed method based on Krone-Unger

Concentration Level: Low

DQI	QC Sample or Measurement Performance Activity	Measurement Performance Criteria
Precision (overall)	Field Duplicate	RPD $\leq 50\%$ (solid matrix) or $\leq 30\%$ (aqueous matrix) if both results $\geq 5x$ PQL <sup>1</sup>
Precision (analytical)	LCS/LCSD <sup>2</sup>	RPD limits presented in Worksheet #12.2b (PCBs), Worksheet #12.2c (herbicides), and Worksheet #12.2d (tributyltin)
Precision (analytical, matrix interference)	MS/MSD	
Accuracy (analytical)	LCS and LCSD <sup>2</sup>	
Accuracy (analytical, matrix interference)	MS and MSD	
Accuracy (analytical, matrix interference)	Surrogate Spike	%R limits presented in Worksheet #12.2b, (PCBs), Worksheet #12.2c (herbicides), and Worksheet #12.2d (tributyltin)
Representativeness (field)	EB ((Rinse)	Not detected > PQL
Representativeness (transport)	Temperature Blank	0°C to 6°C
Representativeness (analytical system)	Laboratory MB	No analytes detected > 1/2 the PQL
Representativeness (matrix interference)	Method-specified matrix cleanup	Performed as required/requested to address challenging sample matrices and chromatographic interference
Sensitivity	MDL and PQL	Adjusted correctly for sample-specific factors (subsample size, moisture content, dilution)
Completeness	Calculation of field and analytical completeness	>90% completeness
Accuracy (analytical, matrix interference)	Second column/second detector quantification <sup>3</sup>	RPD $\leq 40\%$
Sensitivity	MDL	MDL at or below the analyte-specific PALs listed in Worksheets #15.4a and b, #15.5, and #15.6
		Conducted and updated at least annually <sup>3</sup>
Sensitivity	PQL <sup>3</sup>	Established at or above the low point of calibration curve

<sup>1</sup> For low-level results (one or both detected values  $\leq 5x$  PQL) or when one result is a non-detection, the control limit is absolute difference  $\leq 2x$  PQL (solid matrix) or  $\leq$  PQL (aqueous matrix). Non-detected values will be assigned the nominal value of the MDL for making this comparison.

<sup>2</sup> LCSDs are not a method requirement; however, if LCSD results are reported, the LCSD%Rs and LCS/LCSD RPD will be evaluated.

<sup>3</sup> This method requirement will only be reviewed to complete definitive (Stage 4) data validation.

## WORKSHEET #12.3A

### MEASUREMENT PERFORMANCE CRITERIA: PCBs AS CONGENERS

Matrix: Solid and aqueous  
Analytical Group/Method: HRGC/HRMS / EPA Method 1668C (EPA, 2010)  
Concentration Level: Low

DQI	QC Sample or Measurement Performance Activity	Measurement Performance Criteria
Precision (overall)	Field Duplicate	RPD $\leq 50\%$ (solid matrix) or $\leq 30\%$ (aqueous matrix) if both results $\geq 5x$ PQL <sup>1</sup>
Precision (analytical)	LCS/LCSD <sup>2</sup>	RPD $\leq 20\%$
Precision (analytical, matrix interference)	MS/MSD	RPD $\leq 25\%$
Accuracy (analytical)	LCS and LCSD <sup>2</sup>	%R limits presented for selected congeners in Worksheet #12.3b
Accuracy (analytical, matrix interference)	MS and MSD	
Representativeness (field)	EB (Rinse)	Not detected > PQL
Representativeness (transport)	Temperature Blank	0°C to 6°C
Representativeness (analytical system)	Laboratory MB	No analytes detected > 1/2 the PQL
Representativeness (matrix interference)	Method-specified matrix cleanup	Performed as required/requested to address challenging sample matrices and chromatographic interference
Sensitivity	MDL and PQL	Adjusted correctly for sample-specific factors (subsample size, moisture content, dilution)
Completeness	Calculation of field and analytical completeness	>90% completeness
Accuracy (analytical, matrix interference)	Target analyte identification criteria <sup>3</sup>	Method requirements for S/N, m/z, peak presence, and peak relative retention time are listed in Section 16 of method 1668C; all criteria must be met for a detected result to be confirmed.
Accuracy (analytical, matrix interference)	Labeled standards <sup>3</sup>	%R limits presented in Worksheet #12.3b
Accuracy (analytical, matrix interference)	Cleanup standards <sup>3</sup>	%R limits presented in Worksheet #12.3b
Sensitivity	EDLs <sup>3</sup>	Sample- and analyte-specific EDLs calculated and reported by method-required procedures
Sensitivity	MDL	MDL at or below the analyte-specific PALs listed in Worksheets #15.7a and b
Sensitivity	PQL <sup>3</sup>	Conducted and updated at least annually <sup>3</sup>
Sensitivity	PQL <sup>3</sup>	Established at or above the low point of calibration curve

<sup>1</sup> For low-level results (one or both detected values  $\leq 5x$  PQL) or when one result is a non-detection, the control limit is absolute difference  $\leq 2x$  PQL (solid matrix) or  $\leq$ PQL (aqueous matrix). Non-detected values will be assigned the nominal value of the MDL for making this comparison.

<sup>2</sup> LCSDs are not a method requirement; however, if LCSD results are reported, the LCSD%Rs and LCS/LCSD RPD will be evaluated.

<sup>3</sup> This method requirement will only be reviewed to complete definitive (Stage 4) data validation.

S/N = signal to noise ratio  
m/z = mass to charge ratio

## WORKSHEET #12.4A

### MEASUREMENT PERFORMANCE CRITERIA: ORGANOCHLORINE PESTICIDES

Matrix: Solid and aqueous

Analytical Group/Method: Solid: GC/MS/MS / EPA Method 1699M (EPA, 2007); Aqueous, HVS PUF cartridges, and HVS solids: HRGC/HRMS / EPA Method 1699 (EPA, 2007)

Concentration Level: Low

DQI	QC Sample or Measurement Performance Activity	Measurement Performance Criteria
Precision (overall)	Field Duplicate	RPD $\leq 50\%$ (solid matrix) or $\leq 30\%$ (aqueous matrix) if both results $\geq 5x$ PQL <sup>1</sup>
Precision (analytical)	LCS/LCSD <sup>2</sup>	RPD limits presented in Worksheets #12.4b, #12.4c, and #12d
Precision (analytical, matrix interference)	MS/MSD	
Accuracy (analytical)	LCS and LCSD <sup>2</sup>	
Accuracy (analytical, matrix interference)	MS and MSD	%R limits presented in Worksheets #12.4b, #12.4c, and #12d
Representativeness (field)	EB (Rinse)	Not detected > PQL
Representativeness (transport)	Temperature Blank	0°C to 6°C
Representativeness (analytical system)	Laboratory MB	No analytes detected > ½ the PQL
Representativeness (matrix interference)	Method-specified matrix cleanup	Performed as required/requested to address challenging sample matrices and chromatographic interference
Sensitivity	MDL and PQL	Adjusted correctly for sample-specific factors (subsample size, moisture content, dilution)
Completeness	Calculation of field and analytical completeness	>90% completeness
Accuracy (analytical, matrix interference)	Labeled standards <sup>3</sup>	%R limits presented in Worksheets #12.4b, #12.4c, and #12d
Sensitivity	MDL	MDL at or below the analyte-specific PALs listed in Worksheets #15.8a and b Conducted and updated at least annually <sup>3</sup>
Sensitivity	PQL <sup>3</sup>	Established at or above the low point of calibration curve

<sup>1</sup> For low-level results (one or both detected values  $\leq 5x$  PQL) or when one result is a non-detection, the control limit is absolute difference  $\leq 2x$  PQL (solid matrix) or  $\leq$ PQL (aqueous matrix). Non-detected values will be assigned the nominal value of the MDL for making this comparison.

<sup>2</sup> LCSDs are not a method requirement; however, if LCSD results are reported, the LCSD %Rs and LCS/LCSD RPD will be evaluated.

<sup>3</sup> This method requirement will only be reviewed to complete definitive (Stage 4) data validation.

HVS = high volume sampling

PUF = polyurethane foam

## WORKSHEET #12.5A MEASUREMENT PERFORMANCE CRITERIA: PCDD/PCDFs

Matrix: Solid and aqueous  
Analytical Group/Method: HRGC/HRMS / EPA Method 1613B (EPA, 2010)  
Concentration Level: Low

DQI	QC Sample or Measurement Performance Activity	Measurement Performance Criteria
Precision (overall)	Field Duplicate	RPD $\leq$ 50% (solid matrix) or $\leq$ 30% (aqueous matrix) if both results $\geq$ 5x PQL <sup>1</sup>
Precision (analytical)	LCS/LCSD <sup>2</sup>	RPD $\leq$ 20%
Precision (analytical, matrix interference)	MS/MSD	
Accuracy (analytical)	LCS and LCSD <sup>2</sup>	%R limits presented in Worksheet #12.5b
Accuracy (analytical, matrix interference)	MS and MSD	%R within 70-130% (CFA) or 80-120% (SGS)
Representativeness (field)	EB (Rinse)	Not detected > PQL
Representativeness (transport)	Temperature Blank	0°C to 6°C
Representativeness (analytical system)	Laboratory MB	No analytes detected > 1/2 the PQL
Representativeness (matrix interference)	Method-specified matrix cleanup	Performed as required/requested to address challenging sample matrices and chromatographic interference
Sensitivity	Results reported as EMPC	Ratio of quantification ion m/z outside the $\pm$ 15% from the theoretical ratio for the applicable homologue series
Sensitivity	MDL and PQL	Adjusted correctly for sample-specific factors (subsample size, moisture content, dilution)
Completeness	Calculation of field and analytical completeness	>90% completeness
Accuracy (analytical, matrix interference)	Second column/second detector quantification for 2,3,7,8-TCDF <sup>3</sup>	Quantify result from 2,3,7,8-TCDF-specific column
Accuracy (analytical, matrix interference)	Target analyte identification criteria <sup>3</sup>	Method requirements for S/N, m/z, peak presence, and peak relative retention time are listed in Section 16 of method 1613B; all criteria must be met for a detected result to be confirmed. If all criteria except m/z are met, report result as an EMPC.
Accuracy (analytical, matrix interference)	Labeled standards <sup>3</sup>	%R limits for samples presented in Worksheet #12.5b
Sensitivity	EDLs	Sample- and analyte-specific EDLs calculated and reported by method-required procedures <sup>3</sup>
		EDL at or below the analyte-specific PALs listed in Worksheets #15.9a and b
Sensitivity	Laboratory MDL determination <sup>3</sup>	Conducted and updated at least annually
Sensitivity	PQL <sup>3</sup>	Established at or above the low point of calibration curve

<sup>1</sup> For low-level results (one or both detected values  $\leq$ 5x PQL) or when one result is a non-detection, the control limit is absolute difference  $\leq$ 2x PQL (solid matrix) or  $\leq$ PQL (aqueous matrix). Non-detected values will be assigned the nominal value of the EDL for making this comparison.

<sup>2</sup> LCSDs are not a method requirement; however, if LCSD results are reported, the LCSD%Rs and LCS/LCSD RPD will be evaluated.

<sup>3</sup> This method requirement will only be reviewed to complete definitive (Stage 4) data validation.

EMPC = estimated maximum potential concentration

TCDF = tetrachlorodibenzofuran

Sensitivity	MDL	MDL at or below the analyte-specific PALs listed in Worksheets #15.8a and b
		Conducted and updated at least annually
Sensitivity	PQL <sup>3</sup>	Established at or above the low point of calibration curve

<sup>1</sup> For low-level results (one or both detected values  $\leq 5x$  PQL) or when one result is a non-detection, the control limit is absolute difference  $\leq 2x$  PQL. Non-detected values will be assigned the nominal value of the MDL for making this comparison.

<sup>2</sup> LCSDs are required by Method NWTPH-Dx if laboratory duplicates are not performed.

<sup>3</sup> This method requirement will only be reviewed to complete definitive (Stage 4) data validation.

GC/FID = gas chromatography/flame ionization detector

TPH = total petroleum hydrocarbons

**WORKSHEET #12.8B**  
**ANALYTE-SPECIFIC LIMITS FOR TPH (NWTPH-Dx)**

<b>Chemical</b>	<b>CASRN</b>	<b>Solid Matrix Accuracy Control Limits (%R)</b>	<b>Solid Matrix Precision Control Limits (RPD)</b>	<b>Aqueous Matrix Accuracy Control Limits (%R)</b>	<b>Aqueous Matrix Precision Control Limits (RPD)</b>
Diesel range organics (C <sub>10</sub> -C <sub>25</sub> )	68334-30-5	42-134	40	NA	NA
Residual range organics (C <sub>25</sub> -C <sub>35</sub> )	Not available	48-141	40	NA	NA
<b>Surrogates</b>					
o-Terphenyl	84-15-1	50-150	NA	NA	NA
n-Triacontane	638-68-6	50-150	NA	NA	NA

**WORKSHEET #12.9**

**MEASUREMENT PERFORMANCE CRITERIA: TOTAL AND DISSOLVED ORGANIC CARBON**

Matrix: Solid (TOC) and aqueous (TOC and DOC)  
 Analytical Group/Method: Carbonaceous Analyzer / SW-846 Method 9060A  
 Concentration Level: Low

DQI	QC Sample or Measurement Performance Activity	Measurement Performance Criteria
Precision (overall)	Field Duplicate	RPD $\leq$ 50% (solid matrix) or $\leq$ 30% (aqueous matrix) if both results $\geq$ 5x PQL <sup>1</sup>
Precision (analytical)	LCS/LCSD <sup>2</sup>	RPD <20% (solid) or 17% (aqueous)
Precision (analytical, matrix interference)	MS/MSD	
Accuracy (analytical)	LCS and LCSD <sup>2</sup>	%R within 72-122% (solid) or 83-117% (aqueous)
Accuracy (analytical, matrix interference)	MS and MSD	
Representativeness (field)	EB (Rinse)	Not detected > PQL
Representativeness (analytical system)	Laboratory MB	No analytes detected > 1/2 the PQL
Sensitivity	MDL and PQL	Adjusted correctly for sample-specific factors (subsample size, moisture content, dilution)
Completeness	Calculation of field and analytical completeness	>90% completeness
Sensitivity	MDL	PQL at or below the analyte-specific PALs listed in Worksheet #15.13
		Conducted and updated at least annually <sup>3</sup>
Sensitivity	PQL <sup>3</sup>	Established at or above the low point of calibration curve

<sup>1</sup> For low-level results (one or both detected values  $\leq$ 5x PQL) or when one result is a non-detection, the control limit is absolute difference  $\leq$ 2x PQL (solid matrix) or  $\leq$ PQL (aqueous matrix). Non-detected values will be assigned the nominal value of the MDL for making this comparison.

<sup>2</sup> LCSDs are not a method requirement; however, if LCSD results are reported, the LCSD%Rs and LCS/LCSD RPD will be evaluated.

<sup>3</sup> This method requirement will only be reviewed to complete definitive (Stage 4) data validation.

DOC = dissolved organic carbon

TOC = total organic carbon

## WORKSHEET #12.10

### MEASUREMENT PERFORMANCE CRITERIA: GEOTECHNICAL PARAMETERS

The following analytical methods may be used to characterize geotechnical parameters collected to characterize solid and aqueous media at the SIB Project Area. These analyses, if performed, will be required to meet the requirements presented in the analytical methods and the laboratory SOPs, and no project-specific measurement performance criteria are presented.

Parameter	Matrix	Analytical Method <sup>1</sup>
Grain Size (fraction <75 µm)	Solid	ASTM D1140
Total Solids/Natural Moisture Content	Solid	ASTM D2216 <sup>2</sup>
Density (specimen)	Solid	ASTM D7263
Total Suspended Solids (TSS)	Aqueous	SM2540D
Total Solids	Aqueous and Solid	EPA Method 160.3 (EPA, 1971)
Particle Size (sieve)	Solid	ASTM D6913
Particle Size (hydrometer)	Solid	ASTM D422
Atterberg Limits	Solid	ASTM D4318
Specific Gravity (soil solids)	Solid	ASTM D854
Direct Shear Test	Solid	ASTM D3080
Consolidated Undrained Triaxial Test with Pore Pressure	Solid	ASTM D4767
Consolidation Tests	Solid	ASTM D2435

<sup>1</sup> Laboratory SOPs listed in QAPP Worksheet #23.

<sup>2</sup> The method used for geotechnical testing; laboratory-performed chemical analyses will also determine percent solids for moisture correction in accordance with the laboratory-specific SOPs presented in Worksheet #23.

µm = microns

ASTM = ASTM International

**WORKSHEET #12.11****MEASUREMENT PERFORMANCE CRITERIA: WASTE CHARACTERIZATION ANALYSES**

The following analytical methods may be used to characterize aqueous and solid investigation-derived waste (IDW) as required by disposal entities to ensure proper storage and disposal of this material. These analyses, if performed, will be required to meet the requirements presented in the analytical methods and the laboratory SOPs, and no project-specific measurement performance criteria are presented.

<b>Parameter</b>	<b>Matrix</b>	<b>Analytical Method<sup>1</sup></b>
PCBs	Water/Soil	SW8082A
pH	Water	SW9040C
	Soil	SW9045D
Ignitibility (Flash Point)	Water/Soil	SW1020
Percent Solids	Soil	ASTM D2216
Paint Filter Liquids Test	Soil	SW9095B
TCLP <sup>2</sup>	Soil	SW1311
VOCs <sup>3</sup>	Water and soil extract	SW8260C
SVOCs <sup>3</sup>	Water and soil extract	SW8270D
Organochlorine pesticides <sup>3</sup>	Water and soil extract	SW8081B
Metals <sup>3</sup>	Water and soil extract	SW6020B, SW7470A

<sup>1</sup> Laboratory SOPs listed in QAPP Worksheet #23.

<sup>2</sup> Prior to sampling IDW, it must be determined whether TCLP is appropriate. Consult the requirements of the waste disposal facility and applicable Federal, state, or local discharge permits or other requirements.

<sup>3</sup> Analyte lists as presented in 40 CFR 261.24.

SW = method from EPA's SW-846 methods compendium

TCLP = toxicity characteristic leaching procedure

**WORKSHEET #13**  
**SECONDARY DATA CRITERIA AND LIMITATIONS TABLE**

The secondary data that will be used for the SIB Project Area RD has been reviewed in the SAR (HGL, 2021b). This document includes evaluation of sources of contaminants to determine whether they have been adequately investigated and sufficiently controlled or considered such that the RD can proceed. In addition to the SAR, a PDI Work Plan (HGL, 2021c) has been prepared that will be used to direct the specific PDI sampling and analysis activities that are required to complete the data sets needed to complete the RD. Section 2.0 of the SAR and Section 2.0 of the PDI Work Plan identify existing data sources used for this project and evaluate the associated limitations and data gaps.

Notes:

During the May 12, 2021, technical project planning meeting with EPA, it was noted that review timeframe for project stakeholders was not established and the sequence of the PDI field efforts was still being evaluated. Changes to the review timeframes or sequence of field efforts may impact the schedule dates listed above.

\*This deliverable consists of the Design Package, Emergency Response Plan, Institutional Controls Implementation and Assurance Plan, Waste Designation Memorandum, Biological Assessment Report, Clean Water Act Analysis Report, Project Area Monitoring Plan, Construction QA/QC Plan, Operation and Maintenance Plan and Manual, and Transportation and Off-Site Disposal Plan.

## **WORKSHEET #15**

### **PROJECT ACTION LIMITS AND LABORATORY-SPECIFIC DETECTION/QUANTITATION LIMITS**

The project-specific analytical method reference limits and evaluation tables for project sample analyses are presented in Worksheets #15.1 through #15.13. These worksheets include the project analyte lists, the sensitivity limits (MDLs and PQLs) achievable by the project laboratories. These worksheets also present the PALs, which are drawn from multiple sources in accordance with the ROD. These sources include:

- The CULs for riverbank soil/sediment and for surface water presented in Table 17 of the ROD,
- The RALs for sediment focused COCs presented in Table 21 of the ROD, and
- The PTW thresholds for the additional contaminants listed in Table 21 of the ROD.

These PALs have been updated to include Errata #1 and #2 issued by EPA in 2018 and 2020, respectively, and the modifications presented in the Explanation of Significant Differences (EPA, 2019).

Worksheets #15.1 through #15.13 also include those analytes identified as recontamination potential chemicals (RPCs) in solid matrices, as identified in Section 2.3 of the SAR. Worksheets #15.1 through #15.10 indicate whether each analyte is categorized as focused COC/PTW (collectively identified as focused COCs), RPC, or both. In addition to the focused COCs and RPCs, the worksheets include all analytes for which there are matrix-specific CULs listed in ROD Table 17 (identified as COCs).

Worksheet #15.14 presents the analyte lists, regulatory limits, and laboratory PQLs associated with IDW characterization analyses. The laboratory SOPs for the preparation and analytical methods associated with the limits presented in Worksheets #15.1 through #15.14 are listed in Worksheet #23 and are presented in Appendix A.

The laboratory is required to report concentrations at or greater than the MDL as detected results. Results reported as detections with quantitation below the corresponding PQL will be reported by the laboratory with the qualification of “J” to indicate that the result is considered an estimate due to being quantified below the calibrated range. Non-detected results and results below the corresponding detection limit will be reported by the laboratory as non-detected results quantitated as the MDL and qualified “U.” CFA will use EDLs in the place of MDLs for reporting data for PCDD/PCDFs by EPA Method 1613B. Laboratory-assigned qualifiers may be subsequently modified during the data validation process. Some analytes are required to be reported as a total (such as PCBs as Aroclors). These totals will be calculated from the individual component analyte results reported by the laboratory at the data management stage (see Worksheet #35).

In some cases, the laboratory’s MDL is greater than the matrix-specific CUL developed for a target analyte, which is indicated in the methods-specific tables by highlighting the affected CUL. In most cases where the laboratory limits do not meet the CULs, the analytical method selected to support this project is the most sensitive method commercially available and the sensitivity limits

provided by the laboratory are representative of the currently achievable analytical technical capabilities. In other cases, a less sensitive method (such as EPA Method 8082A for PCBs as Aroclors) will be used in conjunction with a more sensitive method. The sensitivity performance for the affected analytes does not meet one of the measurement performance criteria for MDLs (see Worksheet #12) and is a limitation on data usability for comparison to CULs; however, the site is fully characterized, and the analytical results will be of sufficient sensitivity to support RD to address areas of known contamination and the evaluation of recontamination potential from dredging operations.

The laboratory-specific sensitivity limits and control limits presented in the Worksheet #15 tables are subject to change over time based on periodic review at the laboratory. When sensitivity or control limits are updated, the laboratory will present the most up-to-date limits in the associated data reports and alert HGL that analyte-specific limits have been modified. Where changes in sensitivity limits cause an analyte's MDL or PQL to be raised above a PAL, the laboratory must notify HGL immediately. HGL will inform the CMT of this the potential impact on data usability and determine if additional action is required.

Total PCBs	NA	Focused COC, RPC	NA	NA	9,000 <sup>(3)</sup>	75,000 <sup>(3)</sup>

<sup>1</sup> Multiple congeners listed on the same line indicate coeluting compounds that cannot be chromatographically separated.

<sup>2</sup> PCB congener listed by the World Health Organization as exhibiting dioxin-like toxicity.

<sup>3</sup> The ROD presents the screening levels in µg/kg; the PALS in this table have been converted to pg/g (1 µg/kg = 1,000 pg/g) to match the units reported by the analytical laboratory.

pg/g = picograms per gram

Total PCBs	NA	Focused COC, RPC	NA	NA	6.4 <sup>(3)</sup>

<sup>1</sup> Multiple congeners listed on the same line indicate coeluting compounds that cannot be chromatographically separated; congeners are listed in expected order of elution from the chromatographic column.

<sup>2</sup> PCB congener listed by the World Health Organization as exhibiting dioxin-like toxicity.

<sup>3</sup> The ROD presents the screening levels in µg/L; the PALS in this table have been converted to pg/L (1 µg/L = 1E6 pg/L) to match the units reported by the analytical laboratory.  
pg/L = picograms per liter

<sup>1</sup> The ROD presents the screening levels in µg/L; the PALS in this table have been converted to ng/L (1 µg/L = 1,000 ng/L) to match the units reported by the analytical laboratory.

<sup>2</sup> Listed in Table 17 of the ROD, but not an RPC or focused COC. This compound will only be reported for analyses performed on dredge elutriate testing (DRET) extracts to evaluate the potential for contamination of surface waters during dredging operations.

ng/L = nanograms per liter

<sup>1</sup> EDLs will be calculated on a sample-specific basis; the EDLs presented in this worksheet are representative of CFA analytical capabilities. CFA is in the process of integrating new standards into their calibration that will also lower the PQLs for both water and soil media and expects these lower calibrated ranges will be available before project sampling begins.

<sup>2</sup> Although only select PCDD/PCDFs are focused COCs, PTW, or RPCs, all congeners with a TEF will be reported for all samples.

<sup>3</sup> The TEF for human toxicity developed by the World Health Organization in 2005 and adopted by EPA in 2007.

<sup>4</sup> The ROD presents the screening levels in µg/kg; the PALS in this table have been converted to pg/g (1 µg/kg = 1,000 pg/g) to match the units reported by the analytical laboratory.

<sup>5</sup> PTW threshold listed in Table 21 of the ROD.

<sup>6</sup> 2,3,7,8-TCDD TEQs are calculated for each sample by multiplying the concentration of each individual congener by the associated TEF and summing across all congeners.

<sup>7</sup> ROD Table 21 does not list a soil/sediment RAL for 2,3,7,8-TCDD equivalents; the 2,3,7,8-TCDD soil/sediment RAL has been used as a proxy for 2,3,7,8-TCDD equivalents.

TEQ = toxic equivalent

2,3,7,8-TCDD TEQ <sup>5</sup>	NA	NA	NA	NA	10	0.6 <sup>6</sup>

<sup>1</sup> Although only select PCDD/PCDFs are focused COCs, PTW, or RPCs, all congeners with a TEF will be reported for all samples.

<sup>2</sup> SGS PCDD/PCDF data is not reported nor assessed based on MDLs; non-detected results will be reported to the sample-specific EDL.

<sup>3</sup> The TEF for human toxicity developed by the World Health Organization in 2005 and adopted by EPA in 2007.

<sup>4</sup> CULs and RALs presented for informational purposes but are not applicable to non-site stormwater sources. The stormwater PCDD/PCDF load will be calculated using the metered volume of water sampled and will be used to supplement RD decisions to address recontamination potential.

<sup>5</sup> 2,3,7,8-TCDD TEQs are calculated for each sample by multiplying the concentration of each individual congener by the associated TEF and summing across all congeners.

<sup>6</sup> ROD Table 21 does not list a soil/sediment RAL for 2,3,7,8-TCDD equivalents; the 2,3,7,8-TCDD soil/sediment RAL has been used as a proxy for 2,3,7,8-TCDD equivalents.

Copper	7440-50-8	COC	0.35	0.50	2.74
Zinc	7440-66-6	COC	2.92	6.0	36.5

<sup>1</sup> ARI has a Method 6020B modification that allows for a 2x or a 5x concentration of samples to improve sensitivity. However, performing this modification requires samples that do not have elevated mineral concentrations. ARI's experience with stormwater samples indicates that it is unlikely that this modification will be available, but ARI will evaluate samples that are non-detect for arsenic on a sample-specific basis to determine if concentrated analysis is practical.

mg/L = milligrams per liter

TSCA = Toxic Substances Control Act

**WORKSHEET #17**  
**SAMPLING DESIGN AND RATIONALE**

The sampling design and rationale is the subject of the FSP (HGL, 2021a). The design has been developed to meet the DQOs described in Worksheet #11 and includes sampling surface and subsurface soil and sediment, sediment DRET extracts, stormwater, and stormwater solids. Waste characterization samples also will be collected, as needed. Sampling methods, IDs, and location descriptions are provided in Section 4.0 of the FSP. Sample containers, preservation requirements, and hold times are outlined in Worksheet #19/#30, and sample handling and custody procedures are detailed in Worksheet #26/#27.

**WORKSHEET #18**  
**SAMPLING LOCATIONS AND METHODS/SOP REQUIREMENTS TABLES**

Sampling locations and methods/SOP requirements for the SIB PDI are presented in Section 4.0 of the FSP (HGL, 2021a). The SOPs applicable to the field sampling effort are presented in Appendix A of the FSP.

## **WORKSHEETS #19 AND #30**

### **SAMPLE CONTAINERS, PRESERVATION, AND HOLD TIMES**

The following table includes analytical methods used for the PDI field investigation; the associated SOPs are listed in Worksheet #23. Prior to sampling, the project laboratory will be provided with the list of analyses to be performed and required turnaround times. The field sampling team should work with the project laboratory to identify samples for analytical methods that can be combined in the same sampling container to optimize sampling time and reduce shipping costs and sample waste.

Holding times expressed in hours should be measured from the time of collection to the time of preparation or analysis. Holding times expressed in days should be evaluated based on number of calendar days elapsed, with the sampling date considered day “0.”

Sample locations, ID numbers, and medium-specific analyses are presented in Section 4.0 of the FSP (HGL, 2021a). Anticipated concentration levels will likely be low for identified constituents. If a sheen or odor is noted at a sample location, then the sample will be flagged on the CoC as “high” concentration.

## WORKSHEET #19 AND 30.1

### SAMPLE CONTAINERS, PRESERVATION, AND HOLD TIMES

Matrix	Parameter	Analytical and Preparation Method/SOP Reference	Containers	Preservation Requirements	Maximum Holding Time	Archive Holding Time <sup>1</sup>	Laboratory

<sup>1</sup> Material to be archived includes excess sample material, containerized samples submitted but put on hold, or samples submitted as cores.

<sup>2</sup> Analysis of solid matrix samples will also include percent solids determination performed on a subsample from one of the submitted sample containers (see Worksheet #23).

<sup>3</sup> The laboratory procedure is a non-standard guidance document (see Worksheet #23).

<sup>4</sup> DRET, HVS, and TCLP extracts and material subsampled by the laboratory from bulk samples will be containerized, preserved, and stored in accordance with the laboratory's associated analytical method SOPs.

<sup>5</sup> If aqueous wastes containing an observable nonaqueous phase are encountered, the laboratory will be contacted to provide appropriate sampling protocols and containers.

HCl = hydrochloric acid

HNO<sub>3</sub> = nitric acid

L = liter

mL = milliliter

oz = ounce

PE = polyethylene

SM = standard methods for the evaluation of water and wastewater

VOA = volatile organic analysis

Sediment/Soil	Per Worksheet #19/30.1	15 business days	Northwest Testing, Inc. 9120 SW Pioneer Ct Wilsonville, OR 97070 (503) 682-1880	TBD	FedEx	A2LA (Expires 12/31/2022)

<sup>1</sup> Temporary backup analytical services will be requested on an as-needed basis from the listed project supporting laboratories and the associated laboratory networks. Should a project laboratory need to be replaced on a permanent basis, this will be done through HGL's contracting procedures.

<sup>2</sup> CFA is affiliated with GEL; the Charleston, SC facility of GEL will perform the DRET extraction and provide the extracts to CFA for analysis.

A2LA = American Association for Laboratory Accreditation

GEL = GEL Laboratories, LLC

NELAC = National Environmental Laboratories Accreditation Conference

## WORKSHEET #20 FIELD QC SUMMARY

Unless otherwise noted, all field and QC samples listed below will be analyzed for the complete method analyte lists for solid and aqueous samples presented in the method- and matrix-specific tables in Worksheet #15. Field duplicate pairs will be collected at a rate of approximately 1 per 20 field samples. MS/MSD pairs will be collected at a rate of approximately 1 per 20 samples. EBs will be collected at a rate of 1 per 20 samples, with a minimum of one per week per equipment type; however, if samples are collected from sampling ports, dedicated equipment, or equipment that will not be reused, EBs will not be required. The frequency of collection will apply to each sampling event. No field QC samples will be collected in association with IDW characterization sampling or other samples for which the results will receive no validation (such as the geotechnical parameters listed in Worksheet #12.10).

The identification of field QC samples will be performed using the protocols described in Section 4.7.2 of the FSP (HGL, 2021a).

<sup>1</sup> Reference analytical method SOPs in Worksheet #23.

<sup>2</sup> Projected sample locations are shown in the FSP; the number of samples shown is the expected number and subject to change based on subsurface conditions at each location.

<sup>3</sup> The number of field QC samples will be adjusted based on the actual number of field samples collected.

<sup>4</sup> The laboratory will prepare a sample and associated QC for each soil-to-water ratio by weight selected for extraction; see FSP Section 4.2.5.

<sup>5</sup> One breakthrough sample collected per sampling event; samples will be collected using dedicated pumps and conventional EBs are not required.

<sup>6</sup> Submitted from the field as an unused PUF cartridge.

<sup>7</sup> Equipment blanks will only be collected in association with the 11 grab samples from manholes and outfalls; equipment blanks are not required in association with samples from the trap stations.

**WORKSHEET #21**  
**FIELD SOP REFERENCES TABLE**

The field SOPs that will be used by the HGL team are included in Appendix A of the FSP (HGL, 2021a) and will be available to the field sampling teams.

<b>Company</b>	<b>SOP Number</b>	<b>Title</b>	<b>Date Approved</b>

**FIELD EQUIPMENT CALIBRATION, MAINTENANCE, TESTING, AND INSPECTION TABLE**

Field measurement apparatus used by subcontracted consultants, such as bathymetry, will be calibrated and maintained in accordance with their internal procedures and SOPs (see FSP Appendix A [HGL, 2021a]).

Field Equipment	Calibration Activity	Maintenance Activity	Testing Activity	Inspection Activity	Frequency	Acceptance Criteria	CA <sup>2</sup>	Responsible Person	SOP Reference <sup>3</sup>
ORP meter <sup>1</sup>	NA	NA	Single standard calibration check	NA	Daily, before sampling	Two successive reading within $\pm 10$ mV	Recalibrate instrument	Field sampling team	402.01
	Sensitivity verification	NA	NA	NA	Daily, before sampling	ORP should decrease as pH is increased	If ORP increases, correct the polarity of electrodes. If ORP still does not decrease, clean electrodes and repeat procedure.	Field sampling team	402.01
Turbidity meter <sup>1</sup>	Single standard calibration with formazin standard per instrument range used	NA	NA	NA	Daily, before sampling	$\pm 5$ units, 0–100 range; $\pm 0.5$ units, 0–20 range; $\pm 0.2$ units, 0–1 range	Recalibrate instrument	Field sampling team	402.01
Dissolved oxygen meter <sup>1</sup>	NA	NA	Function check	NA	Daily, before sampling	Meter reads $8\% \pm 2\%$	Replace instrument	Field sampling team	402.01

**WORKSHEET #22 (CONTINUED)**  
**FIELD EQUIPMENT CALIBRATION, MAINTENANCE, TESTING, AND INSPECTION TABLE**

Field Equipment	Calibration Activity	Maintenance Activity	Testing Activity	Inspection Activity	Frequency	Acceptance Criteria	CA <sup>2</sup>	Responsible Person	SOP Reference <sup>3</sup>
Aqueous pH meter <sup>1</sup>	2-point calibration with pH buffers	NA	NA	NA	Daily, before sampling	±0.05 pH units for every buffer	If calibration is not achieved, check meter, buffer solutions, and probe; replace if necessary and repeat calibration.	Field sampling team	402.01
Conductance meter <sup>1</sup>	Calibration with potassium chloride standard	NA	NA	NA	Daily, before sampling	±5%	If calibration is not achieved, check meter, standards, probe, and recalibrate.	Field sampling team	402.01
PID	NA	NA	Calibration check with ambient air and 100 ppm isobutylene	NA	Daily, before sampling	Response within 10% of expected value	Adjust instrument settings, recheck.	Field sampling team	A-3
Flow meter	NA	NA	Flow rate check	NA	Every 15 minutes of HVS sample collection	±5% (±0.075 L/min)	Adjust flow rate to 1.5 L/min	Field sampling team	SW-27

<sup>1</sup> Direct reading from real-time probe associated with a flow-through cell.

<sup>2</sup> If CA does not solve the problem, the equipment will be removed from service and replaced until it has been repaired.

<sup>3</sup> See Worksheet #21, Field SOP References Table.

mV = millivolt

ORP = oxidation-reduction potential

ppm = parts per million

**WORKSHEET #23**  
**ANALYTICAL SOP REFERENCES TABLE**

The project analytical SOPs listed below are presented in Appendix A. Laboratory SOPs are subject to periodic review and revision and the laboratory will use the most recent SOP versions at the time of analysis.

Reference Number	Title, Revision Date, and/or Number <sup>1</sup>	Definitive or Screening Data	Instrument	Organization Performing Analysis	Modified for Project Work? <sup>2</sup>
<i>Laboratory Analytical Methods – Environmental Samples</i>					
VOC-8260	Volatile Organic Compounds by GC/MS, Revision 21.0; 10/5/2020	Screening <sup>3</sup>	GC/MS	ALS-Kelso	N
SVM-8270L	Semi-Volatile Organic Compounds by GC/MS Low Level Procedure, Revision 11.0; 12/2/2020	Screening <sup>3</sup>	GC/MS	ALS-Kelso	N
SVM-8270S	Semi-Volatile Organic Compounds by GC/MS Selective Ion Monitoring, Revision 9.0; 12/2/2020	Screening <sup>3</sup>	GC/MS	ALS-Kelso	Y <sup>4</sup>
403S	Polychlorinated Biphenyls (Aroclor) Analysis, Revision 26; 2/11/2020	Screening <sup>3</sup>	GC/ECD	ARI	N
SOC-8151	Chlorinated Herbicides, Revision 19.0; 12/2/2020	Screening <sup>3</sup>	GC/ECD	ALS-Kelso	N
SOC-BUTYL	Butyltins, Revision 16.0; 12/2/2020	Screening <sup>3</sup>	GC/FPD	ALS-Kelso	N
CF-OA-E-003	Analysis of Polychlorinated Biphenyls (PCBs) by High-Resolution Gas Chromatography/High-Resolution Mass Spectrometry (HRGC/HRMS), Revision 9; 3/26/2021	Screening <sup>3</sup>	HRGC/HRMS	CFA	N
HRMS PCBs	Analysis of Polychlorinated Biphenyls, Revision 17; 2/13/2020	Screening <sup>3</sup>	HRGC/HRMS	SGS	N

<sup>1</sup> SOPs are reviewed/revised annually. The current version will be followed at the time of sample receipt.

<sup>2</sup> If method modifications are required to support project work, these modifications must be noted and a full description of the modification, including detailed instructions for field and laboratory personnel, must accompany the SOPs included in Appendix A.

<sup>3</sup> Data validated to EPA Stage 2A will be of screening data quality; 10% of results will be validated to Stage 4 and will be considered to be of definitive data quality (see Worksheet #11 Section 11.6, Worksheet #12 Section 12.3, and Worksheet #36).

<sup>4</sup> The laboratory will use the SOP modifications required to achieve the sensitivity limits presented in Worksheet #15.3a and #15.3b.

<sup>5</sup> Although this method can produce definitive data; when used for IDW characterization, screening level data will be sufficient to meet project DQOs.

<sup>6</sup> Project-specific soil mass to water ratios will be selected based on the ratios expected during dredging activities.

<sup>7</sup> This SOP also includes procedures for performing the paint filter test (Method 9095B).

## WORKSHEET #24 ANALYTICAL INSTRUMENT CALIBRATION TABLE

The CA required in this worksheet will be the responsibility of the bench analysts and the laboratory section manager responsible for each method. Calibration results that are outside the control criteria should trigger CA, unless the discrepancy introduces a potential high bias and associated results are non-detections. Where an instrumental problem cannot be resolved by CA/routine maintenance, the affected instrument must be removed from service. Following necessary repairs, the instrument will be recalibrated and determined to be fully functional before being cleared for return to service.

Instrument	Calibration Procedure	Frequency of Calibration	Acceptance Criteria <sup>1</sup>	CA	SOP Reference <sup>2</sup>
GC/MS and GC/MS-SIM	Instrument tuning with 4-bromofluorobenzene	Prior to ICAL; every 12 hours of instrument operation	Ion peaks meet method requirements	1) <b>Halt analytical sequence</b> 2) Evaluate system 3) Retune and recalibrate as necessary	VOC-8260
	Instrument tuning with DFTPP	Prior to ICAL; every 12 hours of instrument operation	Ion peaks meet method requirements	1) <b>Halt analytical sequence</b> 2) Evaluate system 3) Retune and recalibrate as necessary	SVM-8270L
			DDT breakdown $\leq 20\%$ Benzidine and pentachlorophenol tailing factor $\leq 2$ .		
	Instrument tuning with DFTPP	Prior to ICAL; every 12 hours of instrument operation	Ion peaks meet method requirements Pentachlorophenol tailing factor $\leq 2$ .	1) <b>Halt analytical sequence</b> 2) Evaluate system 3) Retune and recalibrate as necessary	SVM-8270S
	Five-point ICAL for target analytes (six points required for quadratic); lowest concentration standard at or below the PQL.	ICAL prior to sample analysis	Each analyte must meet one of the three options below: Option 1: %RSD for each analyte $\leq 20\%$ ; Option 2: linear least squares regression for each analyte: $r^2 \geq 0.99$ ; Option 3: non-linear least squares regression (quadratic) for each analyte: $r^2 \geq 0.99$ .	1) Evaluate system 2) Recalibrate as necessary	VOC-8260 SVM-8270L SVM-8270S

**WORKSHEET #25**  
**ANALYTICAL INSTRUMENT AND EQUIPMENT MAINTENANCE,**  
**TESTING, AND INSPECTION**

Analytical instrument testing, inspection, maintenance, setup, and calibration will be conducted in accordance with the QC requirements identified in each laboratory's SOPs. In addition, each of the specified analytical methods provides protocols for proper instrument calibration, setup, and critical operating parameters.

Preventive maintenance in the laboratory will be the responsibility of the laboratory personnel and analysts. At a minimum, the preventative maintenance schedules contained in the EPA methods, laboratory SOPs, and in the equipment manufacturer's instructions will be followed. This maintenance includes routine care and cleaning of instruments, and inspection and monitoring of the carrier gases, reagents, solvents, reference materials, and glassware used in analysis. The laboratory bench chemists and section managers will document maintenance of instruments and procedures in maintenance log/record books. Each of the laboratories has SOPs for preventive maintenance that are contained in their individual QA manuals (Appendix A).

If an analytical instrument malfunctions and cannot be substituted or repaired within sample hold times or data delivery times, the laboratory will contact the HGL project chemist to allow for the investigation of sending the samples to an alternative laboratory or use of an alternative methodology that will provide comparable results.

**WORKSHEETS #26 AND #27**  
**SAMPLE HANDLING, CUSTODY, AND DISPOSAL**

Sample shipment procedures will include overnight shipment by commercial courier or direct transport by commercial courier. When samples are collected on a Friday, the FTL will coordinate with the laboratory to ensure that samples can be received and properly handled at the laboratory on Saturday. Note that HGL is indicated as the responsible party in its role as the lead contractor; the individuals and organizations referenced in this worksheet are identified in Worksheet #3/5.

<b>Sample Collection, Packaging, and Shipment</b>
Sample Collection (Personnel/Organization): On-site Staff/HGL
Sample Packaging (Personnel/Organization): On-site Staff/HGL
Coordination of Shipment (Personnel/Organization): FTL/HGL; Sample Receipt Manager/Laboratory
Type of Shipment/Carrier: See Worksheet #19/30.2.
Field Sample Storage (number of days from sample collection): Samples will be held in the field when necessary. Holding times must not be compromised by holding samples in the field.
Special Sample Shipment Considerations: See introductory text.
<b>Sample Receipt and Analysis</b>
Sample Receipt (Personnel/Organization): Sample Management Staff/Laboratory
Sample Custody and Storage (Personnel/Organization): Sample Management Staff/Laboratory
Sample Preparation (Personnel/Organization): Organic Preparation Staff, Inorganic Preparation Staff, and Bench Chemists/Laboratory
Sample Determinative Analysis (Personnel/Organization): Bench Chemists/Laboratory
<b>Sample Archiving</b>
Sample Extract/Digestate Storage (number of days from extraction/digestion): For 6 months from data report release.
Sample Storage: Excess sample material will be archived at $\leq -10^{\circ}\text{C}$ for 1 year unless otherwise directed by the HGL PM.
Biological Sample Storage (number of days from sample collection): Not applicable
<b>Sample Disposal</b>
Personnel/Organization: Sample Management Staff/Laboratory
Number of Days from Analysis: Archived material will be retained no less than 1 year from data report release unless otherwise directed by the HGL PM.

**WORKSHEETS #26 AND #27 (CONTINUED)**  
**SAMPLE HANDLING, CUSTODY, AND DISPOSAL**

**Sample Custody Requirements**

**Field Sample Custody Procedures (sample collection, packaging, shipment, and delivery to the laboratory):**

HGL will maintain CoC records for samples and field QC samples. A sample is defined as being under a person's custody if any of the following conditions exist: (1) it is in his or her possession; (2) it is in his or her view after being in the individual's possession; (3) it was in his or her possession and is locked up; or (4) it is in a designated secure area after being in his or her possession.

Procedures to ensure the custody and integrity of the samples begin at the time of sampling and continue through transport, sample receipt, preparation, analyses, storage, data generation, reporting, and sample disposal. Records concerning the custody and condition of the samples are maintained in the field and laboratory records. Sample containers will be sealed in a manner that will prevent tampering or indicate tampering, should it occur. In no instance will sample containers be sealed with tape.

Sample Labeling: Each sample and field QC sample will have a unique sample ID number assigned in accordance with the sample ID protocols presented in Section 4.7.2 of the FSP (HGL, 2021a). The following information will be included on the label:

- Project ID,
- Sample ID,
- Type of sample matrix,
- Preservative added,
- Date and time of collection,
- Required analytical methods, and
- Sampler's initials.

The sample labels will be placed on the sample containers so as not to obscure QA/QC data on the bottles. Sample information will be printed in a legible manner using a permanent (indelible) ink marker or will be preprinted. Field ID must be sufficient to enable cross referencing with the appropriate sample documentation forms. CoC forms will be completed at the time of collection, including required information and ensuring that the CoC information matches the information on the sample labels.

Sample Packaging: Preservation reagents will be added to sample containers before or immediately after collection of the sample, as indicated in Worksheet #19/30.1. The samples will immediately be placed on ice and will be kept chilled during the workday until packaged for shipment to the laboratory.

**WORKSHEETS #26 AND #27 (CONTINUED)**  
**SAMPLE HANDLING, CUSTODY, AND DISPOSAL**

**Sample Custody Requirements (continued)**

Sample coolers will be supplied by the laboratory. When packaging samples for shipment, the cooler drainage plug will be closed, and the cap will be sealed in place with duct tape. Sample containers will be placed inside sealed plastic bags as a precaution against cross-contamination caused by leakage or breakage. Bagged sample containers will be placed in the coolers in such a manner as to eliminate the chance of breakage during shipment. Ice in plastic bags will be placed in the coolers to keep the samples at 6 °C or less throughout shipment. Each cooler will include a temperature blank, consisting of a 125-mL PE bottle filled with tap water and identified as a temperature blank. Prior to sealing the cooler, the sampler's copy of the CoC forms will be detached and provided to the FTL for the project file. The remaining portion of the completed CoC forms will be attached to the underside of the cooler lid in a sealed plastic bag. The cooler will then be taped shut and at least two completed custody seals will be affixed across the gap between the lid and body of the cooler.

Sample Shipment: Samples collected in the field will be shipped to the laboratory as expeditiously as possible. Sample shipment will be performed in accordance with applicable U.S. Department of Transportation regulations. The samples will be shipped to the laboratory by the procedures identified in this worksheet. Arrangements will be made between HGL and each laboratory POC for samples that are to be delivered to a laboratory on a weekend so that sample condition and holding times are not compromised.

**Laboratory Sample Custody Procedures (receipt of samples, archiving, and disposal):**

The assigned sample custodian(s) and staff are responsible for samples received at the laboratory. In addition to receiving samples, the sample receipt staff is also responsible for documentation of sample receipt and storage before and after sample analysis. Summaries of the minimum laboratory receipt procedures are as follows:

- Upon receipt, sign, date, and document the time of sample receipt on the airbills or other shipping manifests received from the couriers.
- Sign the CoC form assuming custody of the samples. If a CoC form is not received with a set of samples, the laboratory will immediately notify the HGL PM or Sampling and Analysis Coordinator.
- Inspect the sample cooler for integrity and then document the following information:
  - Type of courier and whether the samples were shipped, or hand delivered (copies of the airbills are maintained).
  - Availability and condition of custody information.
  - Sample temperature.
  - If the temperature of the samples upon receipt at the laboratory exceeds the temperature requirements, individual sample containers will be measured. Exceedances will be documented in laboratory records, and the laboratory must contact the HGL PM or Sampling and Analysis Coordinator immediately and document decisions regarding the potentially affected samples.
  - Presence of leaking or broken containers and indication of sample preservation.
- Verify that the holding time has not been exceeded. If a sample has exceeded holding time, the HGL PM or Sampling and Analysis Coordinator must be notified.
- Match the sample container information (e.g., sample tag/label), CoC records, and pertinent information associated with the sample. The sample custodian then verifies sample identity to ensure that information is correct. Inconsistencies are resolved with HGL through the laboratory PM. CA measures are documented before sample analysis proceeds.

**WORKSHEETS #26 AND #27 (CONTINUED)**  
**SAMPLE HANDLING, CUSTODY, AND DISPOSAL**

**Sample Custody Requirements (continued)**

Samples and extracts will be archived at the laboratory in accordance with this worksheet. The laboratory also is responsible for the proper management and disposal of sample residuals and extracts, following applicable Federal, state, and local laws; rules; and regulations.

**Sample ID Procedures:**

Field samples and field QC samples will receive a unique sample ID designation as detailed in FSP Section 4.7.2. Sample IDs will clearly differentiate field QC samples (including duplicates and MS/MSDs) and IDW samples from environmental samples.

**CoC Procedures:**

Documentation of the CoC of the samples is necessary to demonstrate that the integrity of the samples has not been compromised between collection and delivery to the laboratory. A CoC record to document the transfer of custody from the field to the laboratory will accompany each sample cooler. Information requested in the CoC record will be completed. In addition, the airbill number assigned by the overnight courier will be listed on the CoC record or the general logbook. One copy of the CoC form will be retained by the samplers and placed in the project records file. The remaining pages will be sealed in a plastic bag and placed inside of the cooler (attached to the underside of the lid). Upon receipt at the laboratory, the CoC forms will be completed, and a cooler receipt form will be completed. It is the responsibility of the laboratory to document the condition of custody seals and sample integrity upon receipt.

The following sample-specific information concerning the sample will be documented on each CoC form:

- Unique sample ID number;
- Date and time of sample collection;
- Designation of MS/MSD;
- Preservative used;
- Analyses required;
- Name of collector(s);
- Serial numbers of custody seals and transportation cases, if used;
- Custody transfer signatures and dates and times of sample transfer from the field to transporters and to the laboratory or laboratories; and
- Bill of lading or transporter tracking number, if applicable.

In addition to the information above, the field team will record the source of sample (including name, location, and sample type) and location-specific QC (such as field duplicates and ambient blanks) in the field logbook at the time of collection. Sample-specific information also will be recorded on sample-specific sample collection sheets and retained in the project file. Pertinent field data, such as groundwater stabilization parameters, will be recorded in the field logbook and on preprinted forms and retained in the project file.

## WORKSHEET #28 ANALYTICAL QC AND CA

The following tables provide general guidance for the evaluation of QC analyses and the implementation of CA for out-of-control situations. The method-specific acceptance criteria are presented in the applicable tables in Worksheet #12 and Worksheet #15. QC results that are outside the control criteria should trigger CA, unless the discrepancy introduces a potential high bias and associated results are non-detections. The laboratory analyst and the laboratory section manager will be responsible for initiating and completing CA associated with QC discrepancies.

**WORKSHEET #28.1**  
**METHOD QC TABLE – GC/MS, GC/ECD, AND GC/FPD METHODS**

QC Element	Frequency	Method/SOP QC Acceptance Limits	CA	DQI
<b>General QC Elements</b>				
MB	Every analytical batch (maximum of 20 samples)	Target analytes not detected $>1/2$ PQL or $>1/10$ the amount measured in a sample or $1/10$ the regulatory limit (whichever is greater)	1) Rerun 2) Evaluate batch 3) Reanalyze or qualify results, as necessary	Representativeness
LCS (and LCSD, if performed)	Every analytical batch (maximum of 20 samples)	Analyte-specific %R and RPD acceptance criteria	1) Rerun 2) Evaluate batch 3) Reanalyze or qualify results, as necessary	Accuracy (and Precision)
MS/MSD	As indicated on CoC forms, and as required for batch control	Analyte-specific %R and RPD acceptance criteria (%R results NA if parent sample concentration $\geq 4x$ the spike level)	1) Evaluate MS/MSD to assess matrix interference 2) Evaluate batch and qualify results as necessary	Accuracy and Precision
Surrogate Recovery	Every sample	Surrogate-specific %R acceptance criteria	1) Rerun 2) Reanalyze or qualify results, as necessary	Accuracy
<b>Method-Specific Elements – GC/MS Methods 8260C, 8270D, and 8270D-SIM</b>				
Internal Standard Performance	Every sample	Peak area within 50-200% of the peak area in the corresponding CCV	1) Rerun 2) Reanalyze or qualify results, as necessary	Accuracy
		Retention time within $\pm 30$ seconds of the corresponding CCV		
RRT Position	Detected sample results	RRT within $\pm 0.06$ RRT units from the established RRT for each analyte and surrogate	1) Correct problem 2) Recalibrate instrument 3) Reanalyze results, as necessary	Analyte Identification
Mass spectrometer results	Positive results must be confirmed	Spectral match to reference spectrum	1) Analyst must evaluate results to confirm identification if spectral match does not meet criteria 2) Section manager must review analyst's determination	Analyte Identification

**WORKSHEET #28.1 (CONTINUED)**

## WORKSHEET #29 PROJECT DOCUMENTS AND RECORDS

The following is a list of the kinds of project records that should be used and maintained, as well as of the personnel responsible for generating and verifying each record. Records should be maintained in the HGL, laboratory, and other subcontractor (such as construction, design, or data validation firms) project files for a minimum of 5 years or longer as required by the contract. Project documentation, including field data, laboratory data, and electronic files will be maintained in accordance with the Project Data Management Plan described in Section 9.0 of the FSP and the Programmatic Data Management Plan (EPA, 2020a).

Record	Generation	Verification
<b><i>Sample Collection Documents and Records</i></b>		
Field notes (bound logbook)	Field staff	FTL
Sample documentation forms	Field staff	FTL
Tailgate safety meeting forms	SSHO	Corporate H&S Manager
CoC records	Field staff	FTL
Airbills	Field staff	FTL
Custody seals	Field staff	FTL
CA forms	PM	Project QA Officer
Photographs	Field staff	PM
GIS data	Field staff	Data Manager
Telephone logs, emails, faxes, and correspondence	Field staff	FTL
<b><i>On-Site Analysis Documents and Records</i></b>		
Equipment calibration logs	Field Staff	FTL
Equipment maintenance, testing, and inspection logs	Field Staff	FTL
Equipment calibration logs	Field Staff	FTL
Field sampling data sheets	Field Staff	FTL
Waste disposal records	FTL	PM
<b><i>Off-Site Analysis Documents and Records</i></b>		
Sample receipt, custody, and tracking records	Sample Receipt Staff	Laboratory PM
Standard traceability logs	Analytical Staff	Section Manager/QA Manager
Equipment calibration logs	Analytical Staff	Section Manager/QA Manager
Sample preparation logs	Analytical Staff	Section Manager/QA Manager
Analytical run logs	Analytical Staff	Section Manager/QA Manager
Equipment maintenance, testing, and inspection logs	Analytical Staff	Section Manager/QA Manager
Analytical discrepancy forms	Analytical Staff	Section Manager/QA Manager

**WORKSHEET #29 (CONTINUED)**

Record	Generation	Verification
Reported analytical results	Analytical Staff	Section Manager/QA Manager
Reported results for standards, QC checks, and QC samples	Analytical Staff	Section Manager/QA Manager
Data package completeness checklists	Analytical Staff/Section Manager	Laboratory PM/QA Manager
Sample disposal records	Assigned Laboratory Staff	Laboratory Operations Manager/QA Manager
Extraction and cleanup records	Analytical Staff	Section Manager/QA Manager
Raw data (stored electronically)	Analytical Staff	Database Manager/QA Manager
EDDs	Laboratory Database Manager	Data Manager
Telephone logs, emails, faxes, and correspondence	Laboratory PM	Laboratory Operations Manager
<b><i>Data Assessment Documents and Records</i></b>		
Data validation reports	Data Validator	Data Validation PM/Project Chemist
Database QC spreadsheets	Project Staff	Data Manager
Data usability assessments	Project Chemist	PM
Telephone logs, emails, faxes, and correspondence	Project Staff	PM
<b><i>Deliverables</i></b>		
Project planning documents, including Sufficiency Assessment, Data Gap Analysis, FSP, UFP-QAPP, Health and Safety Plan	PM and Design Team	QA Officer
Project deliverables, including project management reports; PDI Evaluation Report; Basis of Design Report; RD Work Plan; Treatability Study Reports; and Preliminary (30%), Pre-Final (95%), and Final (100%) RDs with supporting plans, evaluations, and reports	PM and Design Team	QA Officer
Telephone logs, emails, faxes, and correspondence	All project staff	PM
Permits	FTL	PM
Maps and figures	Graphics Staff	PM
EDDs	Project Database Staff	Data Manager

H&S = health and safety

## WORKSHEETS #31, 32, AND 33 ASSESSMENTS AND CA

The planned project assessment activities are described below. In addition to the planned activities listed below, all on-site workers will monitor project activities on an ongoing basis to ensure compliance with project plans, good work practices, and H&S requirements. If a non-conforming or unsafe condition is observed, all site workers have the authority to stop work until the condition is addressed.

### ASSESSMENTS:

Assessment Type	Responsible Personnel and Organization	Number and Frequency	Estimated Dates	Assessment Deliverable	Deliverable Due Date
Review of FSP, UFP-QAPP, SOPs, and Health and Safety Plan with field staff.	FTL	Prior to sampling startup and with new field staff prior to assignment	January-February and July-October 2022	Completed acknowledgment signature pages	48 hours following assessment
Ongoing review to ensure that work is being performed in accordance with project planning documents	FTL	Ongoing during fieldwork phases	January-February and July-October 2022	Daily progress reports	24 hours following conclusion of business day
Logbook and field form review	FTL	Daily	January-February and July-October 2022	NA: corrections will be made directly to reviewed documents	24 hours following assessment
Laboratory Assessment for Appropriate Certifications, Capacity, and QAPP Review with staff.	HGL Chemistry QA Manager	Prior to sampling mobilization and as new laboratories are contracted	June 2021	Receipt of copies of certifications. Email traffic concerning lab capacity prior to sampling startup. QAPP sign-off sheet received from laboratory.	48 hours following assessment
On-Site Laboratory Audit	HGL Project QA Officer	During initial sampling events at SIB Project Area	July 2022	Laboratory audit report	Preliminary assessment: 5 business days after audit conclusion Final Report: 20 business days after audit conclusion

**WORKSHEETS #31, 32, AND 33 (CONTINUED)  
ASSESSMENTS AND CA**

**ASSESSMENTS:**

<b>Assessment Type</b>	<b>Responsible Personnel and Organization</b>	<b>Number and Frequency</b>	<b>Estimated Dates</b>	<b>Assessment Deliverable</b>	<b>Deliverable Due Date</b>
On-Site Field Audit	HGL Project QA Officer	During initial sampling events at SIB Project Area	July 2022	Field audit report	Preliminary assessment: 5 business days after audit conclusion Final Report: 20 business days after audit conclusion
Tailgate safety meeting	FTL	Daily	January-February and July-October 2022	Verbal debriefing and daily sign-off log. If a safety incident occurs, a Supervisor Injury Employee Report is completed.	Weekly; safety incidents will be reported to the PM and Corporate H&S Manager immediately
Field sampling and CoC form review against QAPP requirements	HGL Sample Coordinator	Daily	January-February and July-October 2022	Corrections will be made directly to reviewed documents; communication may be in the form of email.	24 hours following assessment
Data validation	Data validation subcontractor	Per sample delivery group	February-April and August-December 2022	Communication may be in the form of email traffic clarification of the analytical report or Cas because of deficiencies identified in the validation process.	24 hours following assessment
Laboratory report deliverables and analytical results against QAPP requirements	HGL Chemistry QA Manager	As discrepancies are identified in the validation process	January-February and July-October 2022	Memorandum or email to PM and Laboratory PM	72 hours following assessment

**WORKSHEETS #31, 32, AND 33 (CONTINUED)**  
**ASSESSMENTS AND CA**

The responsibilities for assessment response and implementation of corrective action are described below. In all cases, corrective action will be monitored and assessed by different personnel than those tasked with implementing the corrective action. The project QA Officer, who is independent from the project management and execution team, has the final authority to determine if corrective action has been satisfactorily implemented, except for H&S corrective action, which is under the final authority of the Corporate H&S Manager.

**ASSESSMENT RESPONSE AND CA:**

<b>Assessment Type</b>	<b>Individual(s) Notified of Findings</b>	<b>Assessment Response Documentation</b>	<b>Nature of the Deficiencies Documentation</b>	<b>Time Frame for Response</b>	<b>Responsibility for Implementing CA</b>	<b>Responsibility for Monitoring CA</b>
Review of QAPP, SOPs, and Site Safety and Health Plan with Field Staff	FTL	Completed acknowledgement signature pages	Daily Activity Reports	24 hours following assessment	FTL	HGL PM
Ongoing review to ensure that work is performed in accordance with QAPPs.	HGL PM	Interim CA documented pending final approval	Daily QC Reports	By close of same business day	FTL	HGL PM and QA Officer
Logbook and Field Form Review	FTL	Corrections will be made directly to reviewed documents	Daily QC Reports	NA	FTL	HGL PM
Laboratory Assessment for Appropriate Certifications, Capacity, and QAPP Review with Staff	HGL Chemistry QA Manager	Response to email or memorandum	Readiness Review	48 hours after notification	Laboratory PM	HGL Chemistry QA Manager
Tailgate Safety Meeting	FTL	Included as part of the process of the Supervisor Injury Employee Report	Data QC Reports	24 hours after notification	HGL PM	HGL Corporate H&S Manager
Field Sampling and CoC Form Review Against QAPP Requirements	HGL Sampling and Analysis Coordinator	Response to email	Data QC Reports	48 hours after notification	FTL	HGL PM

<b>Assessment Type</b>	<b>Individual(s) Notified of Findings</b>	<b>Assessment Response Documentation</b>	<b>Nature of the Deficiencies Documentation</b>	<b>Time Frame for Response</b>	<b>Responsibility for Implementing CA</b>	<b>Responsibility for Monitoring CA</b>
Data Validation	HGL Chemistry QA Manager	If required, laboratory reports will be amended, and corrections noted in the analytical narrative and contained with the validation report.	Data Validation Reports	1 business week	HGL PM	HGL Chemistry QA Manager
Laboratory Report Deliverables and Analytical Results Against QAPP Requirements	HGL Chemistry QA Manager	If required, laboratory reports will be amended, and corrections noted in the analytical narrative.	Data Validation Reports	72 hours after notification	Laboratory PM	Laboratory QA Manager HGL Chemistry QA Manager

**WORKSHEET #34**  
**DATA VERIFICATION AND VALIDATION INPUTS**

This worksheet lists the inputs that will be used during data verification and validation. Inputs include planning documents, field records, and laboratory records. Data verification is a check that specified activities involved in collecting and analyzing samples have been completed and documented, and that the necessary records (objective evidence) are available to proceed to data validation. Data validation is the evaluation of conformance to stated requirements, including those in the contract, methods, SOPs, and planning documents.

<b>Item</b>	<b>Description</b>	<b>Data Generated Internally or Externally</b>	<b>Verification (completeness)</b>	<b>Validation (conformance to specifications)</b>

**WORKSHEET #35**  
**DATA VERIFICATION PROCEDURES**

Verification Input	Description	Responsible for Verification
CoC (shipping)	CoC forms will be reviewed upon completion and verified against the packed sample coolers and project sampling requirements. This QC check will be verified by initialing the CoC form next to the shipper's signature. A copy of the CoC form will be retained in the project file and the original and one copy will be taped inside the cooler in a waterproof bag.	FTL
Log review	Log reviews will be performed daily. This review will be performed to verify that field monitoring equipment was maintained, calibrated, and operated properly. In addition, the review will verify that required information has been correctly documented in the field logbooks and sample documentation sheets.	FTL
CoC (receipt)	CoC forms will be reviewed and compared to cooler contents. Discrepancies (sample bottles, sample IDs, requested methods) will be communicated to the Laboratory PM for resolution with the HGL Sampling and Analysis Coordinator, FTL, and PM.	Laboratory Sample Receipt Manager Laboratory PM
Analytical data report	Data used to prepare analytical data reports will be reviewed at multiple levels throughout the laboratory. The requirements for this review process are described in each laboratory's quality manual. No data reports will be delivered to HGL without the necessary internal approval.	Laboratory QA Manager
Analytical data report	A review will be conducted to ensure that the appropriate analytical sample fractions have been submitted, appropriate sample IDs have been used, and the correct analytical methods have been used.	HGL Sampling and Analysis Coordinator
Analytical data report <sup>1</sup>	Analytical reports will be reviewed to ensure that required forms, case narratives, samples, CoC forms, logbooks, and raw data have been included.	Data Validator
EDD (export)	Laboratory analytical data and geotechnical testing results will be reported in an EDD that is compatible with the EquIS data management program using the valid values presented in Appendix A of the Program Data Management Plan (EPA, 2020a).	Laboratory Database Manager
EDD (import)	EDD nonconformances from the laboratory will be reviewed and addressed before the data is processed further. The EDD also will be reviewed to ensure it is in the correct format and it contains the correct valid values. Errors or warnings are addressed before processing the data further.	HGL Data Manager
Project database	Results requiring reporting as totals will be calculated in accordance with Section 6 and Table A-2 of the Program Data Management Plan and will be entered into the database. Data qualifiers identified by the data validation reports will be applied to a working output file and imported into the database. Data modified by manual entry will receive a 100% QC check for accuracy and completeness. Prior to final approval, each EDD output will receive a 10% QC check of electronically reported results against the hard copy laboratory reports. EDD outputs to the Portland Harbor Interim Database will be formatted in accordance with the requirements of the EDD Specifications included as Attachment A to the Program Data Management Plan.	HGL Data Manager

<sup>1</sup> This verification step is performed as part of the data validation process described in Worksheet #36.

## WORKSHEET #36 DATA VALIDATION PROCEDURES

Analytical methods that will be used and the level of data quality (screening or definitive) that the data review process will be required to support are identified below.

Validation Stage	Matrix	Analytical SOP <sup>1</sup>	Validation Criteria	Data Validator
<b>Data Review Step Iia</b>				
Data Verification	All	All	Package Completeness Holding Times: Worksheet #19/#30 Narrative: Additional items noted for resolution or clarification	Ecochem or LDC staff validator
Data Validation – Screening (Stage 2A)	Sediment, soil, DRET extracts, and stormwater	See Worksheet #23 method category “Laboratory Analytical Methods – Environmental Samples”	<u>SDGs representing 90% of results</u> : Data quality elements as defined for Stage 2A data validation in EPA, 2009 DQIs: General and method-specific criteria presented in Worksheets #12, #15, and #28 Qualification: EPA CLP NFG <sup>2</sup> and EPA Region 10 Guidance (EPA, 2014)	Ecochem or LDC staff validator
Data Validation – Definitive (Stage 4)			<u>SDGs representing 10% of results</u> : Data quality elements as defined for Stage 4 data validation in EPA, 2009 DQIs: General and method-specific criteria presented in Worksheets #12, #15, #24, and #28 Qualification: EPA CLP NFG <sup>2</sup> and EPA Region 10 Guidance (EPA, 2014)	Ecochem or LDC staff validator

NFG = National Functional Guidelines

**WORKSHEET #36 (CONTINUED)**  
**DATA VALIDATION PROCEDURES**

An overview of the data validation process is presented in the following table.

<b>Validation Stage</b>	<b>Validation Input</b>	<b>Description</b>	<b>Person Responsible for Validation</b>
<b><i>Data Review Step Iia</i></b>			
Data Verification	Laboratory data reports (see Worksheet #35)	The validator will verify data package completeness, review case narratives, evaluate sample delivery and condition, and evaluate preparation and analysis holding times (Worksheet #19/#30).	Ecochem or LDC staff validator
Data Validation	Laboratory data reports	The data validator will perform an evaluation of sample- and batch-related QC results as required for each method as applicable for the stage of data validation. The validation protocols in the NFG will be modified as necessary to accommodate differences between the requirements for analysis performed in accordance with the CLP SOW and the requirements for analyses using the non-CLP methods used for this project.	Ecochem or LDC staff validator
<b><i>Data Review Step Iib</i></b>			
Senior Review	Data validation reports	Senior review of reports to approve of validation results and final qualifiers; overall evaluation of analytical performance against QAPP requirements.	HGL Chemistry QA Manager
Overall Assessment	Project documentation (Worksheet #31/#32/#33)	Complete project dataset and documentation: Determine whether the sampling plan was executed as specified (that is, the number, location, and type of field samples were collected and analyzed as specified in the work plan); evaluate whether sampling procedures were followed with respect to equipment and proper sampling support (for example, techniques, equipment, decontamination, volume, temperature, and preservatives).	HGL PM

## WORKSHEET #37 DATA USABILITY ASSESSMENT

**Summarize the usability assessment process and the procedures, including interim steps and statistics, equations, and computer algorithms that will be used:**

The data assessment team will perform the operations summarized in Worksheets #35 and #36 to evaluate sampling team and laboratory compliance with the requirements with this QAPP and other project planning documents. Evaluation activities will be documented in the QA reports listed in Worksheet #29 and will be used to assess the usability of project data in levels of detail ranging from an analyte- and sample-specific basis to the overall dataset for the sampling event. The PARCCS DQIs and formulas used to evaluate data quality are presented in Worksheet #12, with the accuracy and sensitivity requirements presented on an analyte- and matrix-specific basis in the Worksheet #15 tables.

**Describe the evaluative procedures used to assess overall measurement error associated with the project:**

The assessment will include an evaluation of the QC elements relating to DQIs precision, accuracy, representativeness, comparability, completeness (both sample collection and analytical), and sensitivity (see Worksheet #12). Data that is rejected during the validation process in accordance with the data qualification conventions (Worksheet #36) will be evaluated against the project DQOs (Worksheet #11) by the HGL Chemistry QA Manager to determine if rejection is the appropriate final decision for the affected data. In addition, the HGL Chemistry QA Manager will evaluate DQI performance to determine whether any data points are of insufficient quality for the intended use, even if the affected results did not require rejection under the validation conventions. The impact of data gaps resulting from sampling incompleteness or rejected data will be evaluated in a data quality evaluation included as an appendix to the PDI Evaluation Report.

**Identify the personnel responsible for performing the usability assessment:**

Project team PMs, project chemists, and data managers identified in Worksheet #3/#5.

**Describe the documentation that will be generated during usability assessment and how usability assessment results will be presented so that they identify trends, relationships (correlations), and anomalies:**

Evaluation activities will be documented in the QA reports listed in Worksheet #29. Project deliverables that present analytical data will include a section addressing data quality and any limitations or gaps in the data set that were identified during the data evaluation process and the potential impact on decision making.

## **NON-STANDARD TESTING PROCEDURE SUMMARY**

For

### **ELUTRIATE PREPARATIONS**

Revision: 2  
March 23, 2020

Prepared by: Jeff Coronado

#### **SCOPE AND APPLICATION**

The removal of sediments from waterways by dredging generates concern about the possible release of contaminants into the water column. This document describes three commonly used procedures for estimating the magnitude of this release; Effluent Elutriate Procedure (EET, formerly Modified Elutriate Test, MET), Standard Elutriate Test (SET, a.k.a. Open Water Elutriate, OWE), and Dredge Elutriate Procedure (DRET).

#### **SUMMARY OF PROCEDURES**

Sediment and water from a dredging site are combined in ratios prescribed in each procedure, and mixed for a specified period of time mechanically or by aeration. The resulting slurry is then allowed to settle. The supernatant (elutriate) is then removed by siphoning. "Total" analysis may then be performed on the elutriate as is, or if "Dissolved" analysis are needed an aliquot of the elutriate is filtered through a 0.45 $\mu$ m filter for inorganic analysis while a separate aliquot is centrifuged at high speed then decanted for organic analysis.

#### **EQUIPMENT AND SUPPLIES**

1. 8.7 Liter Glass Cylinder and glass watch glasses.
2. Mechanical Mixer, with stainless steal mixing rod.
3. Stainless Steal spoon and Stainless Steal mixing bowl.
4. Compressed Air and Teflon Tubing.

---

1317 South 13<sup>th</sup> Avenue  
Kelso, WA 98626  
**T:** +1 360 577 7222  
**F:** +1 360 425 9096  
**www.alsglobal.com**

5. Balance able to weigh to the nearest 0.01 gram.
6. 5 gallon glass carboy
7. Vacuum or pressure filtration equipment.
8. High speed centrifuge capable of spinning 1 L bottles.
9. 1L polycarbonate centrifuge bottles.
10. 0.45-micron membrane filters
11. Glass and plastic bottles appropriate for the testing being conducted on the final elutriate.

## **PROCEDURE**

### **Initial Sample Preparation**

Initial sample preparation is identical for all three elutriate tests.

Bulk sediment is typically received in Teflon bags. Remove each sample from the bag and transfer to a stainless steel mixing bowl or large mixing pot, depending on the sample size.

Manually mix the sample with a large stainless steel spoon or mixing paddle, removing any large artifacts such as rocks, pieces of wood, plastic, etc.

Aliquot the mixed sample to glass jars with Teflon lined lids as follows:

- 32 oz. – Elutriate Testing
- 16 oz. – Archive at -20°C
- 8 oz. – Total Analyses (Organics, Metals, and General Chemistry parameters)

### **Effluent Elutriate Test (EET)**

The EET is performed with a slurry concentration (i.e. sediment to site water ration) of 150 g/L (dry weight basis).

---

1317 South 13<sup>th</sup> Avenue  
Kelso, WA 98626  
**T:** +1 360 577 7222  
**F:** +1 360 425 9096  
**www.alsglobal.com**

Determine the bulk density of the sediment (dry weight basis) using ASTM Method E-1109-86, or equivalent.

Calculate the volume of sediment and the corresponding volume of site water required to prepare 8.0 L of slurry using the following equations:

$$A = [(8.0) (150)] \div B$$

$$C = 8.0 - A$$

Where:

A = Volume of Sediment, in L (as rec'd basis)

8.0 = Volume of Elutriation Slurry, in L

150 = Target Concentration of Slurry, in g of dry sediment/L of slurry

B = Bulk Density of Sediment, in g/L (equivalent dry wt. basis)

C = Volume of Site Water, in L

Add the calculated volumes of sediment and site water to the elutriation cylinder (note: CAS custom manufactured cylinders have a total capacity of approximately 8.7 L).

Assemble motor mixer with stainless steel paddle mixer then mechanically mix the sediment/water slurry for 5 minutes. The slurry should be mixed to a uniform consistency, with no unmixed agglomerations of sediment.

Remove the mixing apparatus and secure a Teflon aeration tube to the top of the elutriation cylinder with a clamp, ensuring the end of the tube reaches the bottom of the cylinder. Cover the cylinder with a large watch glass for the duration of aeration and settling.

Pass compressed air through the tube with a flow rate such that the slurry is vigorously mixed for 1 hour.

Note: aeration is used as the means of mixing to ensure that oxidizing conditions will be present in the supernatant during the subsequent settling phase.

Remove the tubing and allow the aerated slurry to settle for 24 hours. Samples that are slow to settle may require increased settling time, or other actions, to

---

1317 South 13<sup>th</sup> Avenue  
Kelso, WA 98626  
**T:** +1 360 577 7222  
**F:** +1 360 425 9096  
**www.alsglobal.com**

produce adequate elutriate volume. Refer to the section on Settling Time Anomalies for further guidance.

After settling an interface is usually evident between the supernatant water and the more concentrated settled material below the interface. Using a Teflon tube, siphon the supernatant at a point midway between the water surface and interface. Care must be taken not to re-suspend settled material.

Siphon the supernatant into a 5 gal. glass carboy then mix to ensure complete uniformity.

If total analysis is requested sub-aliquot final elutriate (mixed supernatant) to containers appropriate for the testing being conducted.

If dissolved analysis is requested filter aliquots for metals and other inorganic analytes through 0.45 $\mu$ m membrane filters, then aliquot to appropriate containers. For dissolved organic analysis transfer an aliquot of elutriate to a polycarbonate bottle, centrifuge at 10,000 times gravity, then decant to appropriate containers. (Sample used for organic analysis should not be filtered because of the tendency of these analytes to adsorb on the filter.)

### **Standard Elutriate Test (SET)**

The SET elutriation is performed with a sediment-to-water ratio of 1:4 on a volume basis at room temperature ( $22 \pm 2^\circ\text{C}$ ).

Subsample approximately 1 L of well mixed sediment and transfer to an elutriation cylinder.

Add a volume of site water equal to 4 times the volume of sediment added in previous step.

Vigorously stir the slurry with a mechanical mixer for 30 minutes. At 10 minute intervals stir the mixture manually to ensure complete mixing.

After the 30 minute mixing period allow the slurry to settle for one hour. Cover the cylinder with a large watch glass during the settling period. Samples that are slow to settle may require increased settling time, or other actions, to produce adequate elutriate volume. Refer to the section on Settling Time Anomalies for further guidance.

---

1317 South 13<sup>th</sup> Avenue  
Kelso, WA 98626  
T: +1 360 577 7222  
F: +1 360 425 9096  
[www.alsglobal.com](http://www.alsglobal.com)

Siphon the supernatant into a 5 gallon glass carboy, taking care not to disturb the settled material. Mix to ensure the elutriate is completely uniform.

Transfer the elutriate to polycarbonate bottles and centrifuge at 2000 rpm for 30 minutes (until visually clear).

Transfer the elutriate to containers appropriate to the testing being conducted.

### **Dredge Elutriate Test (DRET)**

The DRET is performed with a slurry concentration (i.e. sediment to site water ration) of 1 to 10 g/L (dry weight basis). When not specified in the project set-up use 10 g/L.

Determine the bulk density of the sediment (dry weight basis) using ASTM Method E-1109-86, or equivalent.

Calculate the volume of sediment and site water required using the following equations:

$$A = [(8.0) (X)] \div B$$

$$C = 8.0 - A$$

Where:

A = Volume of Sediment, in L (as rec'd basis)

8.0 = Volume of Elutriation Slurry, in L

X = Target Concentration of Slurry, in g of dry sediment/L of slurry

B = Bulk Density of Sediment, in g/L (equivalent dry wt. basis)

C = Volume of Site Water, in L

Add the calculated volumes of sediment and site water to the elutriation cylinder (note: CAS custom manufactured cylinders have a total capacity of approximately 8.7 L).

Assemble motor mixer with stainless steel paddle mixer then mechanically mix the sediment/water slurry for 5 minutes. The slurry should be mixed to a uniform consistency, with no unmixed agglomerations of sediment.

---

1317 South 13<sup>th</sup> Avenue  
Kelso, WA 98626  
**T:** +1 360 577 7222  
**F:** +1 360 425 9096  
**www.alsglobal.com**

Remove the mixing apparatus and secure a Teflon aeration tube to the top of the elutriation cylinder with a clamp, ensuring the end of the tube reaches the bottom of the cylinder. Cover the cylinder with a large watch glass for the duration of aeration and settling.

Pass compressed air through the tube with a flow rate such that the slurry is vigorously mixed for 1 hour.

Note: aeration is used as the means of mixing to ensure that oxidizing conditions will be present in the supernatant during the subsequent settling phase.

Remove the tubing and allow the aerated slurry to settle for 1 hour. Samples that are slow to settle may require increased settling time, or other actions, to produce adequate elutriate volume. Refer to the section on Settling Time Anomalies for further guidance.

After settling an interface is usually evident between the supernatant water and the more concentrated settled material below the interface. Using a Teflon tube, siphon the supernatant at a point 2 inches above the interface. Care must be taken not to re-suspend settled material.

Siphon the supernatant into a 5 gal. carboy then mix to ensure complete uniformity.

Split the elutriate for total and dissolved analysis. Aliquot the fraction for total analysis to containers appropriate for the testing being conducted.

Filter aliquots for metals and other inorganic analytes through 0.45 $\mu$ m membrane filters, then transfer to appropriate containers. For dissolved organic analysis transfer an aliquot of elutriate to a polycarbonate bottle, centrifuge at 10,000 times gravity, then decant to appropriate containers. (Sample used for organic analysis should not be filtered because of the tendency of these analytes to adsorb on the filter.)

### **Settling Time Anomalies**

Samples with a silt/clay fraction that is slow to settle are occasionally encountered. In these instances obtaining adequate elutriate volume to perform the required testing can be difficult. Three options are available when this situation is encountered. The final

---

1317 South 13<sup>th</sup> Avenue  
Kelso, WA 98626  
**T:** +1 360 577 7222  
**F:** +1 360 425 9096  
**[www.alsglobal.com](http://www.alsglobal.com)**

solution may require a combination of all three. In all cases when deviation from the settling protocols are needed the client must be consulted regarding corrective action.

1. The prescribed settling time can be extended. In some instances additional settling time will provide adequate volume, however some samples show little additional settling with time.
2. If adequate sediment and site water is available additional elutriates can be set up of the impacted sample(s). The subsequent elutriates can then be combined to provide sufficient volume for testing.
3. In cases where dissolved analyses are being performed aliquots of the elutriate from below the settling interface can be taken and centrifuged. The resulting elutriate can then be used for the analysis of dissolved organic compounds or filtered through a 0.45µm membrane filter for metals and other inorganic analytes.

## Separatory Funnel Liquid-Liquid Extraction

DOCUMENT ID: EXT-3510 REVISION 14.0

Prepared By:   
Organics Manager, Jonathon Walter

Date: 12/1/2020

Prepared By:   
Quality Assurance Manager, Kurt Clarkson

Date: 12/1/2020

Approved By:   
Laboratory Director, Charles (Pat) Byrne

Date: 12-1-20

## 1) Scope & Applicability

- 1.1 This procedure uses techniques described in EPA Method 3510C for extracting nonvolatile and semi-volatile organic compounds from aqueous samples. The procedure also describes concentration techniques suitable for preparing the extract for the appropriate determinative methods.
- 1.2 This method is applicable to the isolation and concentration of water insoluble and slightly water soluble organics in preparation for a variety of determinative methods which use chromatographic procedures.

## 2) Summary of Procedure

- 2.1 A measured volume of sample, usually 100mL-1000mL, is serially extracted at a specified pH with Dichloromethane or Hexane using a separatory funnel.
- 2.2 The extract is dried, concentrated, and (if necessary) exchanged to an appropriate solvent for the determinative procedure. The extract may undergo additional cleanup steps defined in other procedures.

## 3) Definitions

- 3.1 For general definitions applicable to most analyses refer to the SOP for *Sample Batches*, ADM-BATCH.

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. The department supervisor/manager or designee performs final review and sign-off of the data.

## 5) Interferences

- 5.1 Phthalate esters can pose difficulties when performing sample extractions for Organochlorine pesticides, PCBs, and other semi-volatile organics. Phthalates are easily extracted or leached from materials containing plastics during laboratory operations. Interferences from phthalates can best be minimized by avoiding contact with any plastic materials.
- 5.2 Routine cleaning of the extraction glassware is necessary. Refer to the SOP for Organic Extractions Glassware Cleaning.

## 6) Safety

- 6.1 All appropriate safety precautions for handling solvents, reagents and samples must be taken when performing this procedure as referenced in the ALS Kelso Chemical Hygiene Plan and in the ALS Kelso Lab Waste Management Plan.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Refer to the applicable section in the determinative SOP for sample collection,

preservation, and holding times.

- 7.2 The extract holding time is 40 days from sample preparation to analysis for most methods; however the determinative SOP must be consulted.

## 8) Standards, Reagents, and Consumable Materials

- 8.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Refer to the SOP Reagent/Standards Login and Tracking for the complete procedure and documentation requirements.
- 8.2 All prepared reagents should be stored in glass to prevent the leaching of contaminants from plastic containers.
- 8.3 Organic-free reagent water - All references to water in this method refer to organic-free reagent water, as defined in Chapter One of SW-846.
- 8.4 Sodium hydroxide solution (10N), NaOH. Dissolve 40 g NaOH in organic-free reagent water and dilute to 100 ml.
- 8.5 Sodium Chloride (granular), NaCl.
- 8.6 Sodium sulfate (granular, anhydrous), Na<sub>2</sub>SO<sub>4</sub>. Purify by heating at 400°C for 4 hours in a shallow tray.
- 8.7 Sulfuric acid solution (1:1 v/v), H<sub>2</sub>SO<sub>4</sub>, purchased. Specific projects may require the use of concentrated HCl.
- 8.8 Extraction/exchange solvents
- 8.8.1 Dichloromethane, CH<sub>2</sub>Cl<sub>2</sub> - Pesticide quality or equivalent.
  - 8.8.2 Hexane - Pesticide quality or equivalent.
  - 8.8.3 2-Propanol, CH<sub>3</sub>CH(OH)CH<sub>3</sub> - Pesticide quality or equivalent.
  - 8.8.4 Acetonitrile, CH<sub>3</sub>CN - Pesticide quality or equivalent.
- 8.9 Methyl t-butyl ether (MTBE), Pesticide quality or equivalent.

## 9) Apparatus and Equipment

- 9.1 Separatory funnel – Appropriate size, with Teflon stopcock.
- 9.2 Drying column - modified funnel with ground glass bottom. Glass wool is at bottom covered by sulfate.
- 9.3 Kuderna-Danish (K-D) apparatus (Kontes K-570025-0500).
- 9.3.1 Concentrator tube - 10 ml, graduated (Kontes K-570050-1025 or equivalent). A ground-glass stopper is used to prevent evaporation of extracts.
  - 9.3.2 Evaporation flask - 500 ml (Kontes K-570001-500 or equivalent). Attach to concentrator tube with springs, clamps, or equivalent.

- 9.3.3 Snyder column - Three ball macro (Kontes K-503000-0121 or equivalent).
- 9.3.4 Springs - 1/2 inch (Kontes K-662750 or equivalent).
- 9.4 Boiling chips - Pre-cleaned via DCM rinse, approximately 10/40 mesh (silicon carbide or equivalent).
- 9.5 Water bath - Heated, with concentric ring cover, capable of temperature control ( $\pm 5^{\circ}\text{C}$ ). The bath should be used in a hood.
- 9.6 Vials - 2 ml, glass with Teflon lined screw-caps or crimp tops.
- 9.7 pH indicator paper - pH range including the desired extraction pH.
- 9.8 Erlenmeyer fleaker - 250 ml.
- 9.9 Syringe - appropriate size syringe or Eppendorf.
- 9.10 Graduated cylinder - Appropriate size, Class A or validated general lab grade
- 9.11 Graduated pipettes, appropriate size.
- 9.12 Rotary Agitator- 12 and 24 Place Variable Speed Motor.

## 10) Preventative Maintenance

- 10.1 Routine cleaning of the extraction glassware is necessary. Refer to the SOP for Organic Extractions Glassware Cleaning.

## 11) Procedure

- 11.1 Test-specific benchsheets are attached. These benchsheets list such information as solvents, solvent exchanges, weights, and volumes specified for the determinative method. Use the correct benchsheet and record all extraction and sample information. To assist the analyst, a brief description of the procedure is given on the backside of the benchsheet.
- 11.2 Procedure for Sample Extraction
  - 11.2.1 Evaluate each sample for settled solid material or sediment.
    - 11.2.1.1 If the sample contains a small amount of material that will not interfere with the separatory funnel extraction, or the material can be suspended in the aqueous layer by shaking, shake the sample to mix the material into the sample and analyze the entire sample. Mark the sample meniscus on each bottle and proceed to the In-Bottle spiking below.
    - 11.2.1.2 If the amount of material is enough to interfere with sample extraction or functioning of the separatory funnel, the Project Manager should be notified to determine the procedure to be used. In this situation the default procedure is to *completely* decant the liquid portion of the sample (without shaking the sample or after re-settling) into a graduated cylinder to measure the volume. It must be documented on the benchsheet when decanting is performed. Proceed to the Graduated Cylinder spiking below.

- 11.2.2 One set of QC containing matrix spike, duplicate matrix spike, lab control sample and method blank is done for every 20 samples.

**Note:** It is important that the correct spiking process be used. Addition of surrogate and spike is routinely witnessed by a second analyst to assure completeness. Refer to the SOP for the *Addition of Spikes and Surrogates* (EXT-SAS) for general practices and witnessing procedures. Also:

11.2.2.1 Make sure the tip of the spiking pipette or syringe is just below the surface of the sample. The spiking solution should go into the sample, not disperse on top of it.

11.2.2.2 Make sure the body of a plastic pipette/pipettor does not touch the inside of the bottle or graduated cylinder.

### 11.2.3 In-Bottle Spiking

11.2.3.1 Add the surrogate spiking solution into the sample in the bottle.

11.2.3.2 For the LCS and sample(s) in each analytical batch selected for matrix spiking, add the prescribed volume matrix spiking standard into the sample bottle.

**Note:** When spiking into the sample bottle, if the bottle has been filled to the top such that there is no room for the spiking solutions, pipet a small amount of the sample into its separatory funnel prior to spiking.

11.2.3.3 Transfer the sample to the separatory funnel by pouring the entire contents into the funnel (nominally 1L bottle, or smaller). Rinse the sample bottle with a portion of extraction solvent and add the rinsate to the funnel.

**NOTE:** When measuring out the correct volume to add to the units, be sure to measure the volume of organic free DI water for the LCS and the MB prior to the sample. In this manner less glassware will be generated for the glasswasher.

11.2.3.4 Measure and record the sample volume by filling the bottle to the mark with water and measuring the volume with a Class A TC graduated cylinder. Record the sample volume on the benchsheet.

11.2.4 Graduated Cylinder Spiking - used if a portion of the sample was transferred to a graduated cylinder due to solids content (section 11.2.1.2).

11.2.4.1 Record the sample volume on the benchsheet.

11.2.4.2 Add the surrogate spiking solution into the sample in the graduated cylinder.

- 11.2.4.3 For the LCS and sample(s) in each analytical batch selected for matrix spiking, add the prescribed volume matrix spiking standard into the designated sample that was transferred to a graduated cylinder. The LCS is a volume of organic free DI water added to a graduated cylinder.
- 11.2.4.4 Transfer the sample to the separatory funnel by pouring the entire contents into the funnel. Rinse the graduated cylinder with the extraction solvent, but do not rinse the sample bottle containing the remaining solid material. The remaining solid material may be analyzed separately (depending on the Project Manager's instructions) and any remaining target analytes in the solid portion will be accounted for in that analysis.
- 11.3 Check the pH of the sample by spotting a wide-range pH strip with the sample using a Pasteur pipette. If necessary, adjust the pH for the specific determinative method that will be used to analyze the extract. Adjustments in pH are made by using sodium hydroxide solution and/or sulfuric acid solution. Specific projects may require the use of concentrated HCl.
- 11.4 Add 15-60 ml of the appropriate solvent to the separatory funnel.

NOTE: Dichloromethane creates excessive pressure very rapidly; therefore, initial venting should be done immediately after the separatory funnel has been sealed and inverted once. Venting of the separatory funnel should be into a hood to avoid needless exposure of the analyst to solvent vapors.
- 11.5 Seal and shake the separatory funnel venting to release excess pressure. Once vented, the separatory funnels are shaken or tumbled for 1-2 minutes.
- 11.6 Allow the organic layer to separate from the water phase. If the emulsion is more than one-third the size of the solvent layer, the analyst may employ mechanical techniques to complete the phase separation. The optimum technique depends upon the sample and may include stirring, filtration of the emulsion through glass wool, centrifugation, or other physical methods. Collect the solvent extract in a fleaker. If the emulsion cannot be broken, transfer the sample, solvent, and emulsion into the extraction chamber of a continuous extractor and proceed as described in Method 3520, Continuous Liquid - Liquid Extraction or contact the Project Manager.
- 11.7 Repeat the extraction two more times using fresh portions of solvent. Combine the three solvent extracts.
- 11.8 If further pH adjustment and extraction is required, adjust the pH of the aqueous phase to the desired pH. Serially extract three times with 15-60 ml of appropriate solvent, as outlined in Sections 11.4 through 11.6.
- 11.9 Perform the concentration using the Kuderna-Danish (K-D) Technique.
  - 11.9.1 Assemble a Kuderna-Danish (K-D) concentrator by attaching a 10 ml concentrator tube to a 500 ml funnel evaporation flask and rinsing 3 times with DCM. Dry the extract by passing it through a drying column

containing anhydrous sodium sulfate. Collect the dried extract in a K-D concentrator. Rinse the Erlenmeyer flask, which contained the solvent extract and add it to the column to complete the quantitative transfer, ensuring to rinse the funnel.

- 11.9.2 Add one or two clean boiling chips to the flask and attach a three ball Snyder column. Pre-wet the Snyder column by adding about 1 ml of Dichloromethane to the top of the column. Place the K-D apparatus on a hot water bath (15-20°C above the boiling point of the solvent) so that the concentrator tube is partially immersed in the hot water and the entire lower rounded surface of the flask is bathed with hot vapor. Adjust the vertical position of the apparatus and the water temperature as required to complete the concentration in 10-20 minutes. At the proper rate of distillation the balls of the column will actively chatter, but the chambers will not flood. When the apparent volume of liquid reaches 10 ml, remove the K-D apparatus from the water bath and allow it to drain and cool for at least 10 minutes.
- 11.9.3 If a solvent exchange is required, momentarily remove the Snyder column, add 15 ml of the exchange solvent, a new boiling chip, and reattach the Snyder column. Concentrate the extract, raising the temperature of the water bath, if necessary, to maintain proper distillation.
- 11.9.4 Remove the Snyder column and rinse the flask and its lower joints into the concentrator tube with 1-2 ml of Dichloromethane or exchange solvent. If sulfur crystals are a problem, proceed to Method 3660 for cleanup. The extract may be further concentrated by using the technique outlined in the next section or adjusted to 10.0 ml with the solvent last used. Measure the final extract volume using a 10mL graduated pipette.
- 11.10 If further concentration is needed, nitrogen blow-down or micro-Snyder techniques are used to adjust the extract to the final volume required.
  - 11.10.1 Place the concentrator tube in a warm water bath (approximately 35°C) or at room temperature and evaporate the solvent volume to the required level using a gentle stream of clean, dry nitrogen (filtered through a column of activated carbon). Do not let the sample go dry. Alternatively a micro-Snyder can be used to concentrate to desired volume.

**CAUTION:** Do not use plasticized tubing between the carbon trap and the sample.
  - 11.10.2 The internal wall of the tube must be rinsed down several times with the appropriate solvent during the operation. During evaporation, the solvent level in the tube must be positioned to prevent water from condensing into the sample (i.e., the solvent level should be below the level of the water bath). Under normal operating conditions, the extract should not be allowed to become dry.

**CAUTION:** When the volume of solvent is reduced below 1 ml, semivolatiles may be lost.

11.11 Take to final volume and transfer the concentrated extract to a labeled autosampler vial (with a Teflon lined screw-cap or crimp top) or storage vial. Measure the final extract volume using a 1mL graduated pipette. The extracts obtained may now be analyzed for the target analytes using the appropriate determinative technique. The extract holding time is 40 days from sample preparation to analysis.

## 12) QA/QC Requirements

12.1 Ongoing QC Samples required are described in the ALS-Kelso Quality Assurance Manual and in the SOP for Sample Batches. Additional QC Samples may be required in project specific quality assurance plans (QAPP). Refer to the SOP for the determinative method for minimum QC requirements.

12.2 Any reagent blanks, laboratory control samples, or matrix spike samples should be subjected to exactly the same analytical procedures as those used on actual samples.

## 13) Data Reduction and Reporting

13.1 Preparation of all samples must be documented on a bench sheet. All information regarding the sample(s) extracted, aliquoted, QC spiked, extraction steps, etc. must be documented by the person(s) performing the extraction. Bench sheets are completed and a batch lot number is assigned. The Manufacturer's lot numbers or ID's for the reagents are added to bench sheets.

13.2 The bench sheet must be reviewed by the extraction lead, supervisor, or instrument lab analyst. The instrument lab analyst should sign-off on the bench sheet, thus accepting custody of the extracts.

13.3 Following primary data review, all data is reviewed by a secondary analyst. Refer to the SOP for *Laboratory Data Review Process* (ADM-DREV) for details. The person responsible for final review of the bench sheet should assess the overall validity and quality of the results.

## 14) Contingencies for Handling Out-of-Control or Unacceptable Data

14.1 Refer to the SOP for Nonconformance and Corrective Action (ADIN-NCAR) for procedures for corrective action. Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

## 15) Method Performance

15.1 Refer to the reference method for additional method performance data available.

## 16) Pollution Prevention and Waste Management

16.1 The laboratory will comply with all Federal, State and local regulations governing

waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.

17) **Training**

- 17.1 All analysts performing this analysis are required to read and understand this SOP.
- 17.2 Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

18) **Method Modifications**

- 18.1 There are no known modifications in this laboratory standard operating procedure from the reference method.

19) **References**

## Continuous Liquid-Liquid Extraction

DOCUMENT ID: EXT-3520, REV 19.0

Prepared By:   
Organics Manager, Jonathon Walter

Date: 12/1/2020

Prepared By:   
Quality Assurance Manager, Kurt Clarkson

Date: 12/1/2020

Approved By:   
Laboratory Director, Charles (Pat) Byrne

Date: 12-1-20

## 1) Scope & Applicability

- 1.1 This procedure uses techniques described in EPA Method 3520C for extracting nonvolatile and semi-volatile organic compounds from aqueous samples.
- 1.2 This method is applicable to the isolation and concentration of water insoluble and slightly water soluble organics in preparation for a variety of determinative methods which use chromatographic procedures. Refer to the determinative procedure to determine if this procedure is suitable for the analysis being performed.
- 1.3 Continuous Liquid - Liquid Extraction may be used when a solute is to be transferred from one solvent into another. This procedure involves multiple extractions using immiscible solvents. The solvent is reused as the condensate from a total reflux.
- 1.4 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DOD ELAP. QC requirements defined in the SOP *Department of Defense Projects - Laboratory Practices and Project Management* (ADM-DOD) may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 A measured volume of sample is placed in a continuous liquid-liquid extractor, pH adjusted (if necessary), and extracted with an organic solvent for a determined period of time. In this procedure, the extracting solvent has a higher density than that of the aqueous solution being extracted, allowing the reflux of the heavier extracting solvent to be diverted through the sample, extracting the solute, and then siphoned back into the boiling flask.
- 2.2 The extract is dried, concentrated, and (if necessary) exchanged to an appropriate solvent for the determinative procedure. The extract may undergo additional clean-up steps defined in other procedures.

## 3) Definitions

- 3.1 For general definitions applicable to most analyses refer to the SOP for *Sample Batches*, ADM-BATCH.

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. The department supervisor/manager or designee performs final review and sign-off of the data.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency, as described in the SOP *Employee Training and Orientation* (ADM-TRAIN).

## 5) Interferences

- 5.1 Phthalate esters can pose difficulties when performing sample extractions for organochlorine pesticides, PCBs, and other semi-volatile organics. Phthalates are easily extracted or leached from materials containing plastics during laboratory operations. Interferences from phthalates can best be minimized by avoiding contact with any plastic materials.
- 5.2 Rinse the bottom of the reflux condenser with  $\text{CH}_2\text{Cl}_2$  and/or Acetone to eliminate any possible contaminants from entering the extractor.
- 5.3 Rinse all glass surfaces involved in the extraction process thoroughly with  $\text{CH}_2\text{Cl}_2$  (reagent grade or re-distilled). Three rinses are usually adequate.

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.
- 6.2 This method uses Dichloromethane (DCM), a known human carcinogen. Viton brand gloves should be used while rinsing, pouring or transferring the solvent.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Refer to the applicable section in the determinative SOP for sample collection, preservation, and holding times.
- 7.2 The extract holding time is 40 days from sample preparation to analysis unless otherwise specified in the analytical method.

## 8) Standards, Reagents, and Consumable Materials

- 8.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination.
- 8.2 Reagents and Standards must comply with the traceability, labeling and documentation practices specified in the SOPs *Making Entries onto Analytical Records*; and *Reagent and Standards Login and Tracking* (ADM-RLT). The manufacturer lot number of solvents, reagents, standards and supplies used in an extraction procedure shall be recorded on the each analytical record (bench sheet and/or in a logbook).
- 8.3 All stocks, working solutions and sample dilutions should be prepared using deionized water (DI) conforming to ASTM Type I or ASTM Type II reagent water and deemed organic free. For more information on reagent water generation, refer to the related SOP, Operation and Maintenance of Laboratory Reagent Water Systems.
- 8.4 Sodium sulfate (granular or powder, anhydrous),  $\text{Na}_2\text{SO}_4$ . Purify by heating at  $400^\circ\text{C}$  for 4 hours in a shallow tray and rinsing with DCM.
- 8.5 Dichloromethane (DCM) - Pesticide grade or redistilled if batch testing determines that the solvent is suitable for use.
- 8.6 Hexane,  $\text{C}_6\text{H}_{14}$ . Pesticide quality or equivalent.

- 8.7  $\text{H}_3\text{CCH}_2\text{CH}(\text{CH}_3)_2$ . Pesticide quality or equivalent.
- 8.8 Acetone  $\text{CH}_3\text{COCH}_3$  - Pesticide grade or equivalent
- 8.9 Sodium hydroxide solution (10N), NaOH. Dissolve 40 g NaOH in organic-free reagent water and dilute to 100 ml.
- 8.10 Sodium sulfate (granular, anhydrous),  $\text{Na}_2\text{SO}_4$ . Purify by heating at 400°C for 4 hours in a shallow tray and DCM rinsed.
- 8.11 Sulfuric acid solution (1:1 v/v),  $\text{H}_2\text{SO}_4$ .

## 9) Apparatus and Equipment

- 9.1 Continuous liquid/liquid extraction body.
- 9.2 500 ml round bottom flask
- 9.3 Graduated cylinder, 1 liter, Class A, TC
- 9.4 Stir rod, pH paper, and narrow range pH paper.
- 9.5 Allihn condenser
- 9.6 Boiling chips - Approximately 10/40 mesh (silicon carbide or equivalent). Rinsed with DCM using a large modified funnel with a frit prior to use.
- 9.7 Graduated pipettes, 1, 2 and 5mL. Pipets are pre-tested by lot for bias and precision.

## 10) Preventative Maintenance

- 10.1 Routine cleaning of the extraction glassware is necessary. Refer to the SOP for Organic Extractions Glassware Cleaning.

## 11) Procedure

- 11.1 Test-specific benchsheets are referenced. These benchsheets list such information as solvents, solvent exchanges, weights, and volumes specified for the determinative method. Use the correct benchsheet and record all extraction and sample information. To assist the analyst, a brief description of the procedure is given on the backside of the benchsheet.
- 11.2 Rinse the entire unit thoroughly (in the hood) with DCM and wearing proper PPE, discarding the rinse into a DCM rinse container. Add 3 or 4 boiling chips to the flask and attach the flask to the bottom of the unit. Add ~500 ml of extraction solvent to the body of the extractor in preparation for the addition of the sample. Place on grid clamping device and tighten retaining chain when the desired height is attained. Rinse a 1 liter graduated cylinder with DCM which will be used for the addition of the water or sample to the body of the extractor.
- 11.3 Procedure for Sample Extraction
  - 11.3.1 Evaluate each sample for settled solid material or sediment.
    - 11.3.1.1 If the sample contains a small amount of material that will not interfere with the functioning of the continuous extractor, or the material can be suspended in the aqueous layer by shaking, shake

the sample to mix the material into the sample and analyze the entire sample. Mark the sample meniscus on each bottle and proceed to the In-Bottle spiking below.

11.3.1.2 If the amount of material is enough to interfere with sample extraction, the Project Manager should be notified to determine the procedure to be used. In this situation the default procedure is to completely decant the liquid portion of the sample (without shaking the sample or after re-settling) into a graduated cylinder to measure the volume. It must be documented on the benchsheet when decanting is performed. Proceed to the Graduated Cylinder spiking below.

11.3.2 Refer to the determinative SOP (see Table 1 for a list of applicable SOPs) for the preparation, concentration, storage, and expiration for the surrogate, LCS, and MS spiking solutions. These SOPs also list the resulting final spike concentrations. Each standard should be brought to room temperature before using.

**Note:** It is important that the correct spiking process be used. Addition of surrogate and spike is routinely witnessed by a second analyst to assure completeness. Refer to the SOP for the *Addition of Spikes and Surrogates* (EXT-SAS) for general practices and witnessing procedures. Also:

- Make sure the tip of the spiking pipette or syringe is just below the surface of the sample. The spiking solution should go into the sample, not disperse on top of it.
- Make sure the body of a plastic pipette/pipettor does not touch the inside of the bottle or graduated cylinder.

### 11.3.3 In-Bottle Spiking

11.3.3.1 Add the surrogate spiking solution into the batch QC and sample(s).

11.3.3.2 For the LCS and sample(s) in each analytical batch selected for matrix the sample bottle.

11.3.3.3 Transfer the sample to the extraction apparatus by pouring the entire contents into the continuous body (nominally 1 L bottle, or smaller). Rinse the sample bottle with a portion of extraction solvent and add the rinsate to the extractor.

11.3.3.4 Measure and record the sample volume by filling the bottle to the mark with water and measuring the volume with a Class A TC graduated cylinder. Record the sample volume on the benchsheet.

11.3.4 Graduated Cylinder Spiking – used if a portion of the sample was transferred to a graduated cylinder due to solids content (section 11.3.1).

11.3.4.1 Record the sample volume on the benchsheet.

- 11.3.4.2 Add the surrogate spiking solution into the sample in the graduated cylinder.
- 11.3.4.3 For the LCS and sample(s) in each analytical batch selected for matrix spiking, add the prescribed volume of matrix spiking standard into the designated sample that was transferred to a graduated cylinder. The LCS is a volume of organic free DI water added to a graduated cylinder.
- 11.3.4.4 Transfer the sample to the extraction apparatus by pouring the entire contents into the continuous body. Rinse the graduated cylinder with the extraction solvent, but do not rinse the sample bottle containing the remaining solid material. The remaining solid material may be analyzed separately (depending on the Project Manager's instructions) and any remaining target analytes in the solid portion will be accounted for in that analysis.

**NOTE:** When adding organic free DI water or sample to the mouth of the extractor body, be careful not to pour the volume down the side arm siphon.

- 11.3.5 Check the pH of the sample with narrow-range pH paper and adjust the pH, if necessary, to the pH indicated below, using 1:1 (v/v) sulfuric acid or 10N sodium hydroxide. Add 0.5 mL of the appropriate solution initially to samples that require adjustment. Check the pH with narrow range pH paper to ensure the pH is between 1 and 2 or >11. If the initial addition is insufficient to achieve the target pH, the analyst can then proceed with the addition of additional solution in increments of 0.5 mL until the desired pH is achieved. The samples must be mixed thoroughly after each addition of acid or base before checking the pH. Record the pH on the benchsheet.

<u>DETERMINATIVE PROCEDURE</u>	<u>INITIAL EXTRACTION PH</u>	<u>SECONDARY EXTRACTION PH</u>
ORGANOCHLORINE PESTICIDES (8081), (608)	5-9	None
PCBS AS AROCLORS (8082), (608)	5-9	None
SOCs BY GC/MS (8270)	<2	>11
SIM PAH	As Received*	None

\* - "As received" pH is used for SIM PAH analyses or other PAH-specific tests based on Method 8100 extraction pH listed in EPA Method 3520C. The sample pH is measured and recorded but no pH adjustment is made.

- 11.3.6 Adjust the volume in the extractor body to reach the cycling volume point, with extracting solvent (There should be a minimum of 300 ml of CH<sub>2</sub>Cl<sub>2</sub> in the boiling flask. If not, add additional DI water).
- 11.3.7 Attach the reflux condenser to the unit, turn on and raise temperature

setting until unit is cycling properly (2 to 3 drips of solvent per second).

- 11.3.8 Make sure that each continuous liquid - liquid extractor is cycling properly. For proper operation, the water flow must be continuous from the top outlet of the condensers and the condenser must be cold to the touch before extraction begins.
- 11.3.9 Cycle the unit for an 18-24 hour time period. Method 8270LL and 625LL analyses are light-sensitive: cover the extraction flasks completely with aluminum foil.
- 11.3.10 After the cycling period is completed, shut off all of the temperature controls and allow the unit to cool completely. Remove the reflux condenser from the extractor body and clamp securely to the grid apparatus. Remove the extractor body from the grid apparatus, being careful not to spill the extract in the flask.
- 11.3.11 Method 8270 and 625 analyses only: Cap and store the initial extract. Repeat sections 11.3.5 through 11.3.9 using a new aliquot of extraction solvent and making the secondary pH adjustment (pH >11) as specified in the method (see Table 1 of EPA Method 3520C for 8270).
- 11.3.12 Decant off the remaining extraction solvent from the body of the extractor into the correct waste disposal container, and dump the remaining sample into a collection bucket/sink for neutralization (samples at neutral pH do not need neutralized).
- 11.3.13 Rinse the body of the extractor thoroughly in hot tap water before returning to the glasswasher.
- 11.3.14 Pour the remaining extract from the 500 ml flask into a pre-rinsed K-D apparatus through a funnel containing glass wool and anhydrous sodium sulfate. Add one boiling chip to the K-D apparatus and attach a  $\text{CH}_2\text{Cl}_2$  rinsed Snyder column to the top of the K-D apparatus. Place the K-D apparatus on the S-evap. Set to the proper temperature.

**Method 8270 and 625 Analyses Only:** Pour (combine) the initial extraction (acid side) and secondary extract (base side) through a funnel containing glass wool and anhydrous sodium sulfate into a K-D apparatus.

- 11.4 Concentrate the extract to approximately 5-10 mL. Remove the K-D apparatus from the SVAP and allow to cool. Disassemble the K-D apparatus. Depending on the determinative method, the extract may be further concentrated, solvent exchanged, or adjusted to the necessary volume with the solvent last used. For solvent exchange, continue to section 11.5, if further concentration is required; nitrogen blowdown technique (11.6) is used to adjust the extract to the final volume.
- 11.5 Solvent exchange is required for certain analyses in order to obtain a final extract in a solvent compatible with the analytical system used. Exchange solvents are used as listed below.

<u>Determinative Method</u>	<u>Exchange Solvent Required for Analysis</u>	<u>Exchange Solvent Required for Cleanup</u>
8081	Hexane	Hexane
608	Hexane	Hexane
8082	Hexane	Hexane
8270	none	-

#### 11.6 Nitrogen Blowdown Technique

- 11.6.1 Place the concentrator tube in a warm water bath at  $< 35^{\circ}\text{C}$  and evaporate the solvent volume to the required level using a gentle stream of clean, dry nitrogen (filtered through a column of activated carbon). **Do not let the sample go dry.**

**CAUTION:** Do not use plasticized tubing between the carbon trap and the sample.

- 11.6.2 The internal wall of the tube must be rinsed down several times with the appropriate solvent during the operation. During evaporation, the solvent level in the tube must be positioned to prevent water from condensing into the sample (i.e., the solvent level should be below the level of the water bath). Under normal operating conditions, the extract should not be allowed to become dry.

**CAUTION:** When the volume of solvent is reduced below 1 ml, semi-volatile analytes may be lost.

- 11.7 Measure the final extract volume using an appropriate graduated pipet. Transfer the concentrated extract to the appropriate labeled autosampler vial or storage vial. The extracts obtained may now be analyzed for the target analytes using the appropriate determinative technique. The extract holding time is 40 days from sample preparation to analysis

### 12) QA/QC Requirements

- 12.1 Refer to the SOP for the determinative method and *SOP for Sample Batches* (ADM-BATCH) for minimum QC requirements. Project-specific batching protocols may also be required.
- 12.2 Any reagent blanks, laboratory control samples, or matrix spike samples should be subjected to exactly the same analytical procedures as those used on actual samples.
- 12.3 The QC solutions required by the method must be added as described in the analytical method. The amount and identification of QC solutions added must be documented on the bench sheet. Any reagent blanks, laboratory control samples, or matrix spike samples should be subjected to exactly the same analytical procedures as those used on actual samples.

### 13) Data Reduction and Reporting

- 13.1 Preparation of all samples must be documented on a bench sheet. All information regarding the sample(s) extracted, aliquoted, QC spiked, extraction steps, etc. must be documented by the person(s) performing the extraction. Bench sheets are completed

and a batch lot number is assigned. The Manufacturer's lot numbers or ID's for the reagents are added to bench sheets.

- 13.2 The bench sheet must be reviewed by the extraction lead, supervisor, or instrument lab analyst. The instrument lab analyst should sign-off on the bench sheet, thus accepting custody of the extracts.
- 13.3 Following primary data review, all data is reviewed by a secondary analyst. Refer to the *SOP for Laboratory Data Review Process (ADM-DREV)* for details. The person responsible for final review of the bench sheet should assess the overall validity and quality of the results.

#### 14) Contingencies for Handling Out-of-Control or Unacceptable Data

- 14.1 Refer to the SOP for Nonconformance and Corrective Action (ADIN-NCAR) for procedures for corrective action. Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

#### 15) Method Performance

- 15.1 Available method performance data is given in the reference method. In addition, this procedure was validated through single laboratory studies of accuracy and precision as specified in the determinative procedures.

#### 16) Pollution Prevention and Waste Management

- 16.1 The laboratory will comply with all Federal, State and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.

#### 17) Training

- 17.1 All analysts performing this analysis are required to read and understand this SOP.
- 17.2 Training is documented following the *Employee Training and New Employee Orientation (ADM-TRAIN)*.

#### 18) Method Modifications

- 18.1 There are no known modifications in this laboratory standard operating procedure from the reference method.

#### 19) References

## Solid Phase Extraction

DOCUMENT ID: EXT 3535 REV 8.0

Prepared By:   
Sample Prep Manager, Jonathon Walter

Date: 10/11/19

Prepared By:   
Quality Assurance Manager, Carl Degner

Date: 10/14/19

Approved By:   
General Manager, Ambrose Hughey

Date: 10/16/19

## 1) Scope & Applicability

- 1.1. This procedure uses techniques described in EPA 3535A for extracting nonvolatile and semivolatile organic compounds from aqueous samples. The procedure also describes concentration techniques suitable for preparing the extract for the appropriate determinative methods. Currently, the procedure is used for preparation of samples for methods 8081, 8082, 8270, OC Pest-MS2, OP Pest-MS2, 1,4-Dioxane, and Nonylphenols.
- 1.2. This method is applicable to the isolation and concentration of water insoluble and slightly water soluble organics in preparation for a variety of determinative methods which use chromatographic procedures. The procedure may be applied to other methods providing that the analyst demonstrates the ability of the procedure to give data of acceptable quality in that method.
- 1.3. In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DOD ELAP. QC requirements defined in the SOP *Department of Defense Projects - Laboratory Practices and Project Management* (ADM-DOD/ADM-DOD5) may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 Sample preparation procedures vary by analyte group. Extraction of some groups require that the pH of the sample be adjusted to a specified value prior to extraction. Other groups do not require a pH adjustment.
- 2.2 Following any necessary pH adjustment, a measured volume of sample is extracted by passing it through the solid-phase extraction medium (disks or cartridges), which is held in an extraction device designed for vacuum filtration of the sample.
- 2.3 Target analytes are eluted from the solid-phase media using an appropriate solvent, which is collected in a receiving vessel. The resulting solvent extract is dried using sodium sulfate and concentrated, as needed.
- 2.4 As necessary for the specific analysis, the concentrated extract may be exchanged into a solvent compatible with subsequent cleanup procedures or determinative procedures for the measurement of the target analytes.

## 3) Definitions

- 3.1 Batch - A batch of samples is a group of environmental samples that are prepared and/or analyzed together as a unit with the same process and personnel using the same lot(s) of reagents. It is the basic unit for analytical quality control.
  - 3.1.1 Preparation Batch - A preparation batch is composed of one to twenty field samples, all of the same matrix, and with a maximum time between the start of processing of the first and last samples in the batch to be 24 hours.
  - 3.1.2 Analysis Batch - Samples are analyzed in a set referred to as an analysis sequence. The sequence begins with instrument calibration (initial or continuing verification) followed by sample extracts interspersed with calibration standards (CCBs, CCVs, etc.) The sequence ends when the set of samples has been injected or when qualitative and/or quantitative QC criteria indicate an out-of-control situation.

STANDARD OPERATING PROCEDURE

ALS | Environmental - Kelso

Solid Phase Extraction

EXT-3535 Rev. 8.0

Effective: 10/25/2019

Page 3 of 21

3.2 Sample

3.2.1 Field Sample - An environmental sample collected and delivered to the laboratory for analysis; a.k.a., client's sample.

3.2.2 Laboratory Sample - A representative portion, aliquot, or subsample of a field sample upon which laboratory analyses are made and results generated.

3.3 Quality System Matrix - The matrix of an environmental sample is distinguished by its physical and/or chemical state and by the program for which the results are intended. The following sections describe the matrix distinctions. These matrices shall be used for purpose of batch and quality control requirements.

3.3.1 Aqueous - Any groundwater sample, surface water sample, effluent sample, and TCLP or other extract. Specifically excluded are samples of the drinking water matrix and the saline/estuarine water matrix...

3.3.2 Saline/Estuarine water - Any aqueous sample from an ocean or estuary or other salt-water source.

3.3.3 Non-aqueous Liquid - Any organic liquid with <15% settleable solids.

3.4 Liquid-Solid Extraction - A solute is transferred from one solvent into another via partitioning between liquid and solid phases. Initially, the solutes have a higher affinity for the solid than the aqueous solution being extracted. The solutes are then extracted from the solid phase with an organic solvent, in which the solutes have a higher affinity for than the solid phase.

3.5 Matrix Spike/Duplicate Matrix Spike (MS/DMS) Analysis - In the matrix spike analysis, predetermined quantities of target analytes are added to a sample matrix prior to sample preparation and analysis. The purpose of the matrix spike is to evaluate the effects of the sample matrix on the method used for the analysis. Duplicate samples are spiked, and analyzed as a MS/DMS pair. Percent recoveries are calculated for each of the analytes detected. The relative percent difference (RPD) between the duplicate spikes (or samples) is calculated and used to assess analytical precision. The concentration of the spike should be at the mid-point of the calibration range or at levels specified by a project analysis plan.

3.6 Laboratory Duplicates (DUP) - Duplicates are additional replicates of samples that are subjected to the same preparation and analytical scheme as the original sample. The relative percent difference (RPD) between the sample and its duplicate is calculated and used to assess analytical precision.

3.7 Surrogate - Surrogates are organic compounds which are similar to analytes of interest in chemical composition, extraction and chromatography, but which are not normally found in environmental samples. The purpose of the surrogates is to evaluate the preparation and analysis of samples. These compounds are spiked into all blanks, standards, samples and spiked samples prior to extraction and analysis. Percent recoveries are calculated for each surrogate.

3.8 Method Blank (MB) - The method blank is an artificial sample composed of analyte-free water or solid matrix and is designed to monitor the introduction of artifacts into the analytical process. The method blank is carried through the entire analytical procedure.

3.9 Laboratory Control Samples (LCS) - The LCS is an aliquot of analyte free water or analyte free solid to which known amounts target analytes are added. The LCS is prepared and analyzed in exactly the same manner as the samples. The percent

		Page 4 of 21

recovery is compared to established limits and assists in determining whether the batch is in control.

#### 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. The department supervisor/manager or designee performs final review and sign-off of the data.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency as referenced in *Employee Training and Orientation* (ADM-TRAIN).

#### 5) Interferences

- 5.1 The decomposition of some analytes has been demonstrated under basic extraction conditions. Organochlorine pesticides may dechlorinate and phthalate esters may hydrolyze. The rates of these reactions increase with increasing pH and reaction times.
- 5.2 Bonded-phase silica (e.g., C18) will hydrolyze on prolonged exposure to aqueous samples with pH less than 2 or greater than 9. Hydrolysis will increase at the extremes of this pH range and with longer contact times. Hydrolysis may reduce extraction efficiency or cause baseline irregularities. Styrene divinylbenzene (SDB) extraction disks should be considered when hydrolysis is a problem, although pH range with these disks is not unlimited.
- 5.3 Phthalates are a ubiquitous laboratory contaminant. Glass or Teflon extraction apparatus should be used for this method wherever possible because phthalates are used as release agents when molding rigid plastic (e.g., PVC) and as plasticizers for flexible tubing. A method blank should be analyzed, demonstrating that there is no contamination of the sodium sulfate or other reagents listed in this method.
- 5.4 Sample particulates may clog the solid-phase media and result in extremely slow sample extractions. Use of an appropriate filter aid will result in shorter extractions without loss of method performance if clogging is a problem. Even when a filter aid is employed, this method may not be appropriate for aqueous samples with high levels of suspended solids (>1%), as the extraction efficiency may not be sufficient, given the small volumes of solvents employed and the short contact time.

#### 6) Safety

- 6.1 All appropriate safety precautions for handling solvents, reagents and samples must be taken when performing this procedure. This includes the use of personal protective equipment, such as, safety glasses, lab coat and the correct gloves.
- 6.2 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.
- 6.3 This method uses Dichloromethane, a known human carcinogen. Refer to the methylene chloride policy document, ENV-HSE-NA-EX-006-EN for proper handling.

#### 7) Sample Collection, Containers, Preservation, and Storage

	STANDARD OPERATING PROCEDURE	Solid Phase Extraction
	ALS   Environmental - Kelso	EXT-3535 Rev. 8.0
		Effective: 10/25/2019
		Page 5 of 21

- 7.1 Refer to the applicable section in the determinative SOP for sample collection, preservation, and holding times.
- 7.2 The appropriate sample volume may vary with the intended use of the results and, in general, is the volume necessary to provide the analytical sensitivity necessary to meet the objectives of the project. Under ideal conditions, the sample should be collected by completely filling the container. The sample should generally be collected without additional volume and with little or no headspace. Thus, a 1 L sample is collected in a 1 L container, a 250 mL sample is collected in a 250 mL container, not a 1 L container, etc.

## 8) Apparatus and Equipment

- 8.1 Solid phase extraction manifold
  - 8.1.1 Horizon Technologies SPE-DEX controller and SPE-DEX 4790 extractors.
  - 8.1.2 J.T. Baker Speedisk Expanded Extraction Station.
  - 8.1.3 Vac Elut SPS 24 Extraction Station.
  - 8.1.4 Additional equivalent extraction stations may be used if available.
- 8.2 N-EVAP – Nitrogen evaporation apparatus.
- 8.3 Vacuum system – Capable of maintaining approximately 66 cm of mercury.
- 8.4 Graduated cylinders, 1 Liter, Class A, TC.

## 9) Standards, Reagents, and Consumable Materials

- 9.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Standards, reagents and consumable material documentation shall indicate traceability to purchased neat materials or compounds. Refer to the SOP *Reagent/Standards Login and Tracking* (ADM-RTL) for the complete procedure and documentation requirements.
- 9.2 Organic-free reagent water - All references to water in this method refer to organic-free reagent water, as defined in Chapter One of SW-846.
- 9.3 Sodium sulfate (granular, anhydrous), Na<sub>2</sub>SO<sub>4</sub>. Purify by heating at 400°C for 4 hours in a shallow tray and rinsed with DCM.
- 9.4 Extraction/conditioning/exchange solvents
  - 9.4.1 Methylene chloride - Pesticide quality or equivalent reagent grade
  - 9.4.2 Hexane - Pesticide quality or equivalent.
  - 9.4.3 Acetonitrile- HPLC quality or equivalent.
  - 9.4.4 Methanol - HPLC quality or equivalent.
  - 9.4.5 Acetone - Pesticide quality or equivalent.
  - 9.4.6 Diethyl Ether - Pesticide quality or equivalent.
  - 9.4.7 Methyl tert-Butyl Ether (MTBE) - Pesticide quality or equivalent.
  - 9.4.8 Celite 545 – J.T. Baker filter aid.
- 9.5 Solid-phase extraction disks and cartridges

- 9.5.1 J.T. Baker Speedisk 50-mm, or equivalent. Disks are also available in 47-mm and 90-mm diameters, composed of a variety of solid-phase materials. Other solid phases may be employed, provided that adequate performance is demonstrated for the analytes of interest.
  - 9.5.1.1 C18 Speedisk – 50mm C18 extraction disk.
  - 9.5.1.2 DVB Speedisk – 50mm divinylbenzene extraction disk.
  - 9.5.1.3 Oil & Grease Speedisk – 50mm extraction disk for EPA method 1664.
  - 9.5.1.4 Atlantic DVB SPE Disk.
  - 9.5.1.5 Atlantic C18 SPE Disk
- 9.5.2 Waters Porapak RDX SPE cartridges.
- 9.5.3 J.T. Baker C-18 SPE cartridges.
- 9.5.4 Waters AC-2 SepPak
- 9.6 pH indicator paper - pH range including the desired extraction pH.
- 9.7 Autosampler vials - 2 ml, glass with Teflon lined screw-caps or crimp tops.
- 9.8 VOA vials (40 ml) with Teflon Lined Septum.
- 9.9 1000mL Pre-cleaned amber bottles
- 9.10 Graduated pipettes, 1, 2 and 5mL.
- 9.11 Horizon Vortex Dry Disk – 65 mm.

## 10) Preventive Maintenance

- 10.1 All maintenance activities are recorded in a maintenance logbook kept for each instrument. Pertinent information (serial numbers, instrument I.D., etc.) must be in the logbook. The entry in the log must include: date of event, the initials of who performed the work, and a reference to analytical control.
- 10.2 SPE-DEX 4790 Shutdown Procedure
  - 10.2.1 Load an empty disk holder cup onto the platform with the support screen but no disk.
  - 10.2.2 Attach a collection vessel by twisting it a quarter turn to ensure a vacuum tight seal that is snug but not over tight. Use a retaining clip to hold it in place.
  - 10.2.3 Pour hot water into the empty disk holder with support screen and fill half way. While holding down the ABORT key, press the PURGE key. Release once the run light goes on. This will flush and clean the elute check valve from any solvent or debris.
  - 10.2.4 Turn off the vacuum pump and vent it by disconnecting the line on the waste bottle.
  - 10.2.5 Turn off the gas supply.
  - 10.2.6 Turn off the power supply.
  - 10.2.7 Routine cleaning of the extraction glassware is necessary. Refer to EXT-GC, *Organic Extractions Glassware Cleaning*.

## 11) Procedure

- 11.1 The procedures for solid-phase extraction are similar for most analytes. General procedures for sample preparation, pH adjustment, preparation of the extraction apparatus, and extract concentration that apply to all target analytes are described. The procedures for disk washing, disk conditioning, sample extraction, and sample elution vary depending on the target analyte group. Conditions for specific analyte groups and methods are included in test-specific benchsheets attached. These benchsheets also list such information as solvents, solvent exchanges, weights, and volumes specified for the determinative method. Use the correct benchsheet and record all extraction and sample information. To assist the analyst, a brief description of the procedure is given on the backside of the benchsheet.
- 11.2 Specific procedures described in this SOP were developed for a nominal sample size of 1 Liter. Smaller sample volumes can be used as long as analytical sensitivity is not compromised and/or when high levels of the target analytes are anticipated. However, such samples are best collected in an appropriately-sized container.
- 11.3 Prior to extraction, the analyst must evaluate the sample for applicability of the procedure.
- 11.3.1 Target analytes may be bound in the particulate matter in the sample. Sample preparation procedures must ensure that any particulates in the original sample are included in the sample aliquot that is extracted. If the sample contains excessive particulates, alternate procedures should be considered.
- 11.3.2 This method may not be appropriate for aqueous samples with greater than 1% solids, as such samples can be difficult to filter and the extraction efficiency may be reduced as a result of the small volumes of solvents employed and the short contact time. If the particulate load significantly slows or prevents filtration, alternate procedures should be considered.
- 11.3.3 Target analytes may preferentially adhere to the surfaces of the sample container. Bottle rinses are required. As a result, it is not appropriate to extract only part of the sample from a sample container, e.g., 250 mL from a 1-L sample bottle. This process must be approved by the PC and client.
- 11.4 Disk/cartridges preparation
- 11.4.1 Prior to use, the extraction disks/cartridges must undergo washing steps, usually with different solvents. The steps involved depend on the analytes of interest and the sample matrix (See appendix). Wash the extraction apparatus and disk with the volume of the solvent listed in the appendix. Pull a small amount of solvent through the disk with a vacuum. Turn off the vacuum and allow the disk to soak for the time specified in the appendix.
- 11.4.2 Pull the remaining solvent through the disk and allow disk to dry. These steps may need repeated depending on analytes of interest, and whether more than one washing solvent is required (See appendix).
- 11.4.3 The extraction disks are composed of hydrophobic materials that will not allow water to pass efficiently unless they are pre-wetted with a water-miscible solvent before sample extraction. This step is referred to as conditioning, and the solvent used is dependent on the analytes of interest (see appendix).
- NOTE:** For some disks, beginning with the conditioning step, it is CRITICAL that the disk NOT go dry until after the extraction steps are completed. Should a disk accidentally go dry during the conditioning steps, the conditioning steps for that disk MUST be repeated prior to addition of the sample.

11.4.4 For manual SPE, add the conditioning solvent to the extraction apparatus. Apply a vacuum until a few drops of solvent pass through the disk, ensuring that the disk is soaked with solvent. Turn off the vacuum and allow the disk to soak in the solvent for the time listed in the appendix. Once the soaking time is over, apply the vacuum again, drawing all but a thin layer of solvent through the disk. Stop the vacuum just before the disk goes dry. These steps may need repeated depending on analytes of interest, and whether more than one conditioning solvent is required.

## 11.5 Sample Preparation

11.5.1 Mark the level of the sample on the outside of the sample container for later determination of the sample volume used. Shake the container with the cap tightly sealed, to ensure that any particulate matter is evenly distributed throughout the sample. Measure and record the sample volume by filling the bottle to the mark then measuring with a Class A (TC) graduated cylinder.

11.5.2 Prepare a method blank and LCS from a 1L volume of organic-free reagent water, or a volume of reagent water similar to that being used for the samples (e.g., a 250-mL blank should be used when the sample size is 250 mL, etc.). The blank should be prepared in a 1L amber bottle, graduated cylinder, beaker, or other suitable container. Refer to the determinative SOP (see Table 1 for a list of applicable SOPs) for the preparation, concentration, storage, and expiration for the surrogate, LCS, and MS spiking solutions. These SOPs also list the resulting final spike concentrations.

11.5.3 Add any surrogate standards listed in the determinative method to the samples, method blank, and to the other QC samples. Add any spiking standards listed in the determinative method to the appropriate QC samples. Surrogates and spiking compounds are added to the sample in the original container. The container is then recapped and shaken to mix the spiked analytes into the sample.

11.5.4 The extraction of some groups of analytes requires that the pH of the sample be adjusted to a specified value.

11.5.4.1 When pH adjustment is necessary, it should be performed after the surrogates and matrix spiking compounds (if applicable) have been added and mixed with the sample so that they are affected by the pH in the same manner as the target analytes. This step is performed in the original sample container using the method-specified acid or base.

11.5.4.2 Check the pH of the sample by inserting a clean disposable pipette into the water sample and transferring a drop of water onto the pH paper. If necessary, adjust the pH to the range required for specific analysts of internist.

11.5.5 Assemble a manifold for multiple extractions using the appropriate cartridges or disks following the manufacturer's recommendations.

11.5.6 If samples contain significant quantities of particulates, the use of a filter aid or pre-filter is advisable for disk extractions. J.T. Baker Celite 545, or equivalent is recommended. Add approximately 1g to each sample or ~ 3g to each disk prior to washing steps.

11.5.7 After performing the washing and conditioning steps, pour the sample into the reservoir and, under full vacuum, filter it as quickly as the vacuum will allow (or as specified in the appendix).

- 11.5.8 After the sample has passed through the solid-phase media, dry the disk by maintaining vacuum for time specified in the appendix.
- 11.5.9 Remove the entire standard filter assembly from the manifold and insert a collection vial (already in position when using the Horizon System). The collection vial should have sufficient capacity to hold all of the elution solvents. The drip tip of the filtration apparatus should be seated sufficiently below the neck of the collection vial to prevent analyte loss due to splattering when vacuum is applied.

DETERMINATIVE PROCEDURE	INITIAL EXTRACTION pH	SECONDARY EXTRACTION pH
ORGANOCHLORINE PESTICIDES (8081)	2.5	None
PCBS AS AROCLORS (8082)	2.5	None
PCB CONGENERS (8082)	2.5	None
PAHs BY GC/MS (8270-SIM)	5-9	None
CHLORINATED PESTICIDES BY GC/MS/MS	2.5	None
ORGANOPHOSPHORUS PESTICIDES BY GC/MS/MS	5-9	None
1,4-Dioxane	As received	None

- 11.5.10 An initial elution with a water-miscible solvent, i.e., acetone, methanol or acetonitrile, improves the recovery of analytes trapped in water-filled pores of the sorbent. Use of a water miscible solvent is particularly critical when methylene chloride is used as the second elution solvent. With the collection vial in place, add the volume of elution solvent listed in the appendix to the sample bottle. The solvent is then poured from the bottle onto the extraction disk. Allow the solvent to spread out evenly across the disk, then quickly turn the vacuum on and off to pull the first drops of solvent through the disk. Allow the disk to soak for the periods indicated in the appendix.
- 11.5.11 Rinse the sample bottle with the second solvent listed in the appendix. Transfer this solvent rinse to the extraction disk. If needed, use a disposable pipette to rinse the sides of the extraction apparatus with solvent from the bottle. Draw about half of the solvent through the disk and then release the vacuum. Allow the remaining elution solvent to soak the disk and particulates for the time specified in the appendix before drawing the remaining solvent through the disk under vacuum. When using a filtration aid, adjust the volume of elution solvent so that the entire filtration bed is initially submerged. Repeat the bottle rinsing step as listed in the appendix, continuing to collect the solvent in the vial.
- 11.5.12 Dry the combined extracts in the collection vial by passing the extract through dry disk or syringe packed with sodium sulfate, then quantitatively transferring the extract to an additional collection vial or culture tube. The procedure for using dry disk is included in Appendix A. Alternative drying techniques may be employed if analyte recovery is unaffected.

11.5.13 The extract may now be subjected to cleanup using the appropriate determinative technique(s). Refer to the applicable SOPs.

11.5.14 After drying the extract, and any additional cleanup, perform the nitrogen blowdown (see below) to evaporate the solvent to the appropriate final volume. Measure the final volume with the appropriate graduated pipet (8.10). Transfer extract to a labeled autosampler vial, cap and store as per analytical method. The extract holding time is 40 days from sample preparation to analysis.

#### 11.6 Nitrogen concentration Technique Using N-Vap

11.6.1 Place the concentrator tube in a warm water bath (approximately 35°C) and evaporate the solvent volume to the required level using a gentle stream of clean, dry nitrogen (filtered through a column of activated carbon). **Do not let the sample go dry.**

**CAUTION:** Do not use plasticized tubing between the carbon trap and the sample.

11.6.2 The internal wall of the tube must be rinsed down several times with the appropriate solvent during the operation. During evaporation, the solvent level in the tube must be positioned to prevent water from condensing into the sample (i.e., the solvent level should be below the level of the water bath). Under normal operating conditions, the extract should not be allowed to become dry.

**CAUTION:** When the volume of solvent is reduced below 1 ml, semi-volatile analytes may be lost.

#### 11.7 Nitrogen Concentration Technique Using Turbo-Vap

11.7.1 Turn on the power to the Turbo-Vap and set water bath temperature to < 32°C. Set the nitrogen regulator between 8-10 psi.

11.7.2 Place the collector from the Dry-Disk into the Turbo-Vap and evaporate the solvent volume to the required level using a gentle stream of clean, dry nitrogen (filtered through a column of activated carbon). **Do not let the sample go dry.**

11.7.3 The internal wall of the tube must be rinsed down several times with the appropriate solvent during the operation if exchanging solvents. Concentrate to slightly less than the determinative methods final volume.

### 12) QA/QC Requirements

12.1 Refer to the SOP for the determinative method and *SOP for Sample Batches* for minimum QC requirements. Project-specific batching protocols may also be required.

12.2 Any reagent blanks, laboratory control samples, or matrix spike samples should be subjected to exactly the same extraction procedures as those used on actual samples.

12.3 The QC solutions required by the method must be added as described in the analytical method. The amount and identification of QC solutions added must be documented on the bench sheet. Any reagent blanks, laboratory control samples, or matrix spike samples should be subjected to exactly the same analytical procedures as those used on actual samples.

### 13) Data Reduction and Reporting

- 13.1 Preparation of all samples must be documented on a bench sheet. All information regarding the sample(s) extracted, aliquoted, QC spiked, extraction steps, etc. must be documented by the person(s) performing the extraction.
- 13.2 The bench sheet must be reviewed by the extraction lead, supervisor, or instrument lab analyst. The instrument lab analyst should sign-off on the bench sheet, thus accepting custody of the extracts.

#### 14) Method Performance

- 14.1 Available method performance data is given in the reference method. In addition, this procedure was validated through single laboratory studies of accuracy and precision as specified in the determinative procedures.

#### 15) Pollution Prevention and Waste Management

- 15.1 It is the laboratory's practice to minimize the amount of solvents, acids and reagent used to perform this method wherever feasible. Standards are prepared in volumes consistent with methodology and only the amount needed for routine laboratory use is kept on site. The threat to the environment from solvent and reagents used in this method can be minimized when recycled or disposed of properly.
- 15.2 The laboratory will comply with all Federal, State and local regulations governing waste restrictions as specified in the ALS Lab Waste Management Plan.
- 15.3 This method uses Methylene Chloride and any waste generated from this solvent must be placed in the collection cans in the lab. The solvent will then be added to the hazardous waste storage area and recycled off site.
- 15.4 This method uses non-halogenated solvents and any waste generated from this solvent must be placed in the collection cans in the lab. The solvent will then be added to the hazardous waste storage area and disposed of in accordance with Federal and State regulations

#### 16) Corrective Actions for Out-of-Control Data or Unacceptable Data

- 16.1 Refer to the SOP for *Nonconformance and Corrective Action Procedures* (ADM-NCAR) for procedures for corrective action. Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.
- 16.2 Handling out-of-control or unacceptable data
  - 16.2.1 On-the-spot corrective actions that are routinely made by analysts and result in acceptable analyses should be documented as normal operating procedures, and no specific documentation need be made other than notations in laboratory maintenance logbooks, run logs, for example.
  - 16.2.2 Some examples when documentation of a nonconformity is required using a Nonconformity and Corrective Action Report (NCAR):
    - Quality control results outside acceptance limits for accuracy and precision.
    - Method blanks or continuing calibration blanks (CCBs) with target analytes above acceptable levels.
    - Sample holding time missed due to laboratory error or operations.
    - Deviations from SOPs or project requirements.
    - Laboratory analysis errors impacting sample or QC results.

- Miscellaneous laboratory errors (spilled sample, incorrect spiking, etc.).
- Sample preservation or handling discrepancies due to laboratory or operations error.
- Customer inquiries concerning data quality or services (when applicable). NCAR not required for simple corrections with no impact to the client.
- Data errors reported to clients, non-conforming re-checks.
- Deficiencies found during internal or external audits.
- Login errors or shipping errors.
- IT issues if there is a significant impact to a client.
- Turnaround time complaints.

## 17) Training

### 17.1 Training outline

17.1.1 Review literature (see references section). Read and understand the SOP. Also review the applicable SDSs for all reagents and standards used. Following the reviews, observe the procedure as performed by an experienced analyst at least three times.

17.1.2 The next training step is to assist in the procedure under the guidance of an experienced analyst. During this period, the analyst is expected to transition from a role of assisting, to performing the procedure with minimal oversight from an experienced analyst.

17.1.3 Perform initial precision and recovery (IPR) study as described above for water samples. Summaries of the IPR are reviewed and signed by the supervisor. Copies may be forwarded to the employee's training file. For applicable tests, IPR studies should be performed in order to be equivalent to NELAC's Initial Demonstration of Capability.

### 17.2 Training is documented following *Employee Training and Orientation* (ADM-TRAIN).

17.2.1 When the analyst training is documented by the supervisor on internal training documentation forms, the supervisor is acknowledging that the analyst has read and understands this SOP and that adequate training has been given to the analyst to competently perform the analysis independently.

## 19) Summary of Changes

Summary of Revision Changes			
Revision Number	Effective Date	Document Editor	Description of Changes
8.0	10/25/201910/25/2019	T. Caron	Reformatted SOP to current ALS format. Minor typographical, grammatical, and formatting revisions. Section 1: Updated Scope and Application Section 5: Updated dated section to current safety practices.; Added DCM safety related to DCM. Section 6: Updates Apparatus and Equipment list. Section 9: Standards, reagents and consumables have been updated. Section 11: Extraction technique and procedural changes to reflect current practice. Tables and Appendices have been updated to reflect current information and determinative SOPs. Hyperlinks to Analytical benchsheets have been added into the SOP. Attachment A: SPE Parameters have been updated.

## 20) Attachments and Appendices

- 20.1 Table 1: Applicable Determinative SOPs.
- 20.2 Appendix A: Dry Disc Procedure.
- 20.3 Attachment A: Test-Specific SPE Parameters.

### APPENDIX A Dry Disk Procedure

1. Turn on vacuum to the Horizon dry disk manifold, attach flasks and remove glass cup.
2. Rinse screen with acetone followed by DCM.
3. Rinse glass cup with acetone followed by DCM.
4. Carefully place dry disk membrane on the screen. Take care in handling the disk membrane so as to not tear or scratch the Teflon.
5. Place glass cup on sick/screen and tighten by screwing down.
6. Rinse glass cup and disk with DCM.
7. Rinse glass cup and disk with hexane or the extraction solvent if not hexane.
8. Remove waste collection flask and attach collector. TILT
9. Pour the entire contents of the collected extract onto the top of the disk and apply vacuum. Transfer the sample label from the VOA vial to the collector.
10. Rinse the empty VOA vial 3 times with Hexane or the extraction solvent if not hexane, adding each rinse to the dry disk.
11. Rinse the dry disk apparatus and glass cup and allow all the solvent to pass through. Do not let the remaining water sit on the filter with the vacuum on, as the disk will become permeable after several minutes.
12. Place the sample into the turbo-vap and concentrate to approximately 1 ml.

## Automated Soxhlet Extraction

DOCUMENT ID: EXT-3541, REV 13.0

Prepared By:   
Organics Manager, Jonathon Walter

Date: 12/1/2020

Prepared By:   
Quality Assurance Manager, Kurt Clarkson

Date: 12/1/2020

Approved By:   
Laboratory Director, Charles Pat) Byrne

Date: 12-1-20

## 1) Scope & Applicability

- 1.1 This procedure uses techniques described in EPA Method 3541 for extracting nonvolatile and semi-volatile organic compounds from solids such as soils, sediments, sludges, wastes, and tissues.
- 1.2 This method is applicable to the isolation and concentration of water insoluble and slightly water soluble organics in preparation for a variety of chromatographic procedures.
- 1.3 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DoD ELAP. QC requirements defined in the SOP *Department of Defense Projects – Laboratory Practices and Project Management* (ADM-DOD/ADM-DOD5) may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 This procedure describes the automated Soxhlet extraction process. The Soxhlet extraction ensures constant contact of the sample matrix with the extraction solvent over a period of time. The solid sample is mixed with anhydrous sodium sulfate, placed in an extraction thimble above a plug of glass wool, and extracted using an appropriate solvent on a Soxtherm extractor for a prescribed amount of time.
- 2.2 Following the extraction period, the resulting extract is then dried if necessary, concentrated, and as necessary, exchanged into a solvent compatible with the cleanup or determinative step being employed.

## 3) Definitions

- 3.1 For general definitions applicable to most analyses refer to the SOP for *Sample Batches*, ADM-BATCH.

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. Final review and sign-off of the data is performed by the department supervisor/manager or designee.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency, as described in the determinative method, and in the SOP for *Employee Training and Orientation*.

## 5) Interferences

- 5.1 Phthalate esters can pose difficulties when performing sample extractions for organochlorine pesticides, PCBs, and other semi-volatile organics. Phthalates are easily extracted or leached from materials containing plastics during laboratory operations.

Interferences from phthalates can best be minimized by avoiding contact with any plastic materials.

- 5.2 Contamination by carryover can occur whenever high-concentration and low-concentration samples are sequentially analyzed. All apparatus must be cleaned prior to use on individual samples.
- 5.3 Soap residue, which results in a basic pH on glassware surfaces, may cause degradation of certain analytes. Specifically, Aldrin, Heptachlor, and most OP pesticides will degrade in this situation. All glassware must be rinsed very carefully to avoid this problem.
- 5.4 Refer to SW-846 Method 3500 for additional discussion of interferences. Additional cleanup procedures are described in the applicable ALS SOP.

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.
- 6.2 This method uses Dichloromethane, a known human carcinogen. Refer to the methylene chloride policy document, ENV-HSE-NA-EX-006-EN for proper handling.

<G:\SAFETY\TRAINING\Methylene Chloride\Methylene Chloride - NA 031419.pdf>

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Refer to the applicable section in the determinative SOP for sample collection, preservation, and holding times.
- 7.2 The extract holding time is 40 days from sample preparation to analysis unless otherwise specified in the analytical method.

## 8) Standards, Reagents, and Consumable Materials

- 8.1 Pesticide grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Refer to the SOP *Reagent/Standards Login and Tracking* (ADM-RTL) for the complete procedure and documentation requirements.
- 8.2 Reagents and Standards must comply with the traceability, labeling and documentation practices specified in the SOPS *Making Entries onto Analytical Records*; and *Reagent and Standards Login and Tracking* (ADM-RLT). The manufacturer lot number of solvents, reagents, standards and supplies used in an extraction procedure shall be recorded on the each analytical record (bench sheet and/or in a logbook).
- 8.3 Organic-free reagent water. All references to water in this method refer to organic-free reagent water, as defined in Chapter One of SW-846.

- 8.4 Sodium sulfate (granular, anhydrous),  $\text{Na}_2\text{SO}_4$ . Purify by heating at  $400^\circ\text{C}$  for 4 hours in a shallow tray and rinsed with DCM.
- 8.5 Matrix sand. Purify by heating at  $400^\circ\text{C}$  for 4 hours.
- 8.6 Corn oil
- 8.7 Blank tissue matrix. Analyte free ground turkey or equivalent
- 8.8 Extraction Solvents - Samples are extracted using one of the following solvent systems:
  - 8.8.1 Acetone/Hexane (1:1) (v/v),  $\text{CH}_3\text{COCH}_3/\text{C}_6\text{H}_{14}$ . Pesticide quality or equivalent. Soil, sediment, and aqueous sludge samples.
  - 8.8.2 Dichloromethane/Acetone (1:1 v/v),  $\text{CH}_2\text{Cl}_2/\text{CH}_3\text{COCH}_3$ . Pesticide quality or equivalent. Soil, sediment, and aqueous sludge samples.
- 8.9 Dichloromethane (DCM),  $\text{CH}_2\text{Cl}_2$ . Pesticide quality or equivalent. Other miscellaneous sample matrices.

## 9) Apparatus and Equipment

- 9.1 Soxtherm automated extraction system
  - 9.1.1 Extraction unit controller
  - 9.1.2 Beakers, 54 x 130 mm
  - 9.1.3 Thimbles, 33 mm inner diameter, glass or cellulose
  - 9.1.4 Metal thimble holder
- 9.2 Chiller unit
- 9.3 Boiling chips - Teflon, pre-cleaned by rinsing or extraction.
- 9.4 Water bath - Heated, with concentric ring cover, capable of temperature control ( $\pm 5\text{C}$ ). The bath should be used in a hood.
- 9.5 Vials - Glass, 2 mL capacity, with Teflon lined screw or crimp top.
- 9.6 Glass wool - contaminant free.
- 9.7 Disposable glass Pasteur pipet and bulb.
- 9.8 Apparatus for grinding.
- 9.9 Analytical balance - 0.01 g.
- 9.10 Test tubes

- 9.11 N-Evap™ concentrator with nitrogen source
- 9.12 Turbovap™
- 9.13 Graduated pipettes, 0.5, 1, 2 and 5 mL. Pipettes are pre-tested by lot for accuracy.

## 10) Preventative Maintenance

- 10.1 Routine cleaning of the extraction apparatus is necessary, including all parts exposed to contact with samples, especially extraction thimbles and the Soxtherm apparatus.
- 10.2 The operating temperature of the soxtherm is verified every quarter (March, June, September, and December) with a NIST traceable digital thermometer and probe.
  - 10.2.1 The soxtherm temperature is set at the controller to heat up to the extraction temperature of 140°C. Once the control box reads 140°C the probe is placed directly on each individual heating surface and the temperature is recorded in the soxtherm maintenance logbook (SVMP-SOX-01). Based on a statistical analysis of the results of prior quarterly monitoring, results should fall within limits of 119-141°C.
  - 10.2.2 If the verification is outside of the specified temperature range for any heating position the verification should be re-performed to confirm. If the position reads within the range an additional check for proper cycling is made. If the second verification was acceptable and cycling is correct, the position is considered operational. If the position continues to read outside the range corrective action is necessary, typically in the form of repair of the unit. The position is to be labeled or tagged as "Out of Service" until the problem is corrected and proper temperature verified.
- 10.3 The extraction time on the controller is verified quarterly by recording the start and stop times of an extraction and recording in the soxtherm maintenance logbooks.

## 11) Procedure

- 11.1 Record all extraction and sample information on the applicable benchsheet. To assist the analyst, a brief description of the procedure is given on the backside of the benchsheet. See Attachment A
- 11.2 Sample extraction and extract concentration
  - 11.2.1 Pre-rinse glassware (beaker, thimble with glass wool, and metal clip) before use. To clean the glassware place approximately 75 mL of dichloromethane in beaker and run a short extraction program. Example 10 min. boil time, 1 reduction A, 10 min. extraction, 1 reduction B, 30 min. solvent cooling, temp. 140°C.
  - 11.2.2 Refer to the determinative SOP (see Table 1 for a list of applicable SOPs) for the preparation, concentration, storage, and expiration for the surrogate, LCS, and MS spiking solutions. These SOPs also list the resulting final spike concentrations.

- 11.2.3 Blend the specified sample amount with as little sodium sulfate as possible, so as not to overload the extraction thimble, but still achieve sample drying. The type of sodium sulfate used is dependent upon the method. See Table 2 for further details on which type of sulfate to use.
- 11.2.4 The composition of the MB and LCS is prepared is dependent upon the method. See Table 2 for further details.
- 11.2.5 The MB and LCS is handled in the same manner as the client samples (i.e. drying in hood or any other temporary storage location).
- 11.2.6 Transfer the dry sample into the thimble that contains a plug of glass wool to prevent the sample from dropping into the beaker. Use a second thimble to prevent overfilling or over packing the thimble.
- 11.2.7 Rinse each sample beaker with a small amount of dichloromethane and transfer rinsate to thimble. Perform rinse three times to ensure quantitative transfer.
- 11.2.8 Add the surrogate standard spiking solution onto the samples. For the sample(s) in each analytical batch selected for QC spiking (LCS and MS samples), add the appropriate volume of the appropriate spiking standard. Each standard should be brought to room temperature before using. Addition of surrogate and spike is routinely witnessed by a second analyst to assure completeness. Also, the witness should immediately follow the spiking of each sample with the addition of a small amount of dichloromethane.
- 11.2.9 Add enough dichloromethane or appropriate extraction solvent to cover each sample. This will allow sample to remain covered by solvent during the entire boiling step. If the samples do not equally fill the thimbles feel free to mix and match sample and dichloromethane amounts so that all samples on a single extraction unit have about the same solvent level. Each unit can run a separate program, but a single unit does not allow multiple programs. In the program this step is referred to as boiling time.
- 11.2.10 The boiling step is set to be an hour. During this time the solvent will boil through and over the sample. The majority of the extraction will occur in this step. The temperature of the hot plates should be set for 140°C for dichloromethane and DCM/ACE. When the boiling time is completed the soxtherm needs to be programmed for the proper number of solvent reductions. Solvent reductions happen in 15 mL increments as the calibrated cup is filled by the condensing solvent. When programming the number of reductions the original amount of solvent needs to be taken into consideration. The aim of this step is to bring the solvent level below the tip of the thimble with 50 mL of being the desired amount. In the soxtherm program this is referred to as solvent reduction A.
- 11.2.11 Once the solvent level is below the thimble the extraction time can start. This lasts 1 hour. During this step the solvent drips through the sample to rinse through any remaining analytes. When this is done reduction B can

begin. This step should take the solvent level to the desired amount of  $\geq 10$  mL. Care should be taken during this step, since each beaker seals differently. Some beakers seal very well and others allow more solvent losses. Also all samples are not created equal. Some samples will trap more solvent than others.

11.2.12 If the solvent level has reached the desired stopping point before the programmed numbers of reductions are completed, remove the beaker and immediately cover with foil until cooled. Conversely, if the solvent level of the samples on an instrument is higher than desired, additional solvent reductions can be programmed. Once the desired solvent amount has been reached, remove the beaker and immediately cover with foil.

11.2.13 Nitrogen blowdown is used to further concentrate the extract and to adjust the extract to the final volume. If solvent exchange is required (e.g. GC-ECD analyses) it is done at this point.

11.2.13.1 Using the N-Evap™ or Turbovap™, place the concentrator tube in a warm water bath (approximately 35°C) and evaporate the solvent volume to the required level using a gentle stream of clean, dry nitrogen (filtered through a column of activated carbon).

**CAUTION: Do not use plasticized tubing between the carbon trap and the sample.**

11.2.13.2 The internal wall of the tube must be rinsed down several times with the appropriate final solvent during the operation. During evaporation, the solvent level in the tube must be positioned to prevent water from condensing into the sample (i.e., the solvent level should be below the level of the water bath). The volume of extract in the tube must be monitored during blow down to avoid loss of more volatile analytes. Under normal operating conditions, the extract should not be allowed to become dry.

**CAUTION: When the volume of solvent is reduced below 1 mL, semi-volatile analytes may be lost.**

11.2.13.3 Adjust the extract final volume to the prescribed volume with the solvent last used. Measure the final extract volume using a 0.5, 1, or 2 mL graduated pipette, depending on the test.

11.2.14 If extract cleanup is to be performed, concentrate the extract to the appropriate volume. Proceed to the applicable cleanup procedure and SOP.

11.3 During the final volume step, transfer the extracts to an appropriate storage or autosampler vial. Label the vial with the sample or QC identification and store in the extract storage area. The extracts obtained may now be analyzed for the target analytes

using the appropriate determinative technique. The extract holding time is 40 days from sample preparation to analysis.

## 12) QA/QC Requirements

- 12.1 Refer to the SOP for the determinative method and SOP for Sample Batches (ADM\_BATCH) for minimum QC requirements. Project-specific batching protocols may also be required.
- 12.2 The QC solutions required by the method must be added as described in the analytical method. The amount and identification of QC solutions added must be documented on the bench sheet. Any reagent blanks, laboratory control samples, or matrix spike samples should be subjected to exactly the same analytical procedures as those used on actual samples.

## 13) Data Reduction and Reporting

- 13.1 Preparation of all samples must be documented on a bench sheet. All information regarding the sample(s) extracted, aliquoted, QC spiked, extraction steps, etc. must be documented by the person(s) performing the extraction. Bench sheets are completed and a batch lot number is assigned. The Manufacturer's lot numbers or ID's for the reagents are added to bench sheets.
- 13.2 The bench sheet must be reviewed by the extraction lead, supervisor, or instrument lab analyst. The instrument lab analyst should sign-off on the bench sheet, thus accepting custody of the extracts.
- 13.3 The transfer of custody of completed extracts shall be documented by recording the date, time and extractionist's signature onto the analytical record. The instrument lab analyst shall accept custody of the sample extract(s) by endorsing the analytical record with accompanying date and time, establishing custody for those specific extracts. For additional information refer to the SOP for *Sample Tracking and Internal Chain of Custody*, SMO-SCOC.

## 14) Contingencies for Handling Our-of-Control or Unacceptable Data

- 14.1 Refer to the SOP for *Non Conformance and Corrective Action Procedures* (ADM-NCAR) for procedures for corrective action. Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

## 15) Method Performance

- 15.1 Available method performance data is given in the reference method. In addition, this procedure was validated through single laboratory studies of accuracy and precision as specified in the determinative procedures.

## 16) Pollution Prevention and Waste Management

- 16.1 The laboratory will comply with all Federal, State and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.
- 16.2 This method uses Dichloromethane and any waste generated from this solvent must be placed in the collection cans in the lab. The solvent will then be added to the hazardous waste storage area and recycled off site.

- 16.3 This method uses non-halogenated solvents and any waste generated from this solvent must be placed in the collection cans in the lab. The solvent will then be added to the hazardous waste storage area and disposed of in accordance with Federal and State regulations.

### 17) Training

- 17.1 All analysts performing this analysis are required to read and understand this SOP.  
17.2 Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

### 18) Method Modifications

- 18.1 There are no known modifications in this laboratory standard operating procedure from the reference method.

### 19) References

	STANDARD OPERATING PROCEDURE	Ultrasonic Extraction
	ALS   Environmental - Kelso	EXT-3550, Revision 15.0
		Effective 2/18/2021
		SOP Review: 2/11/2021
		Page 2 of 12

## 1) Scope & Applicability

- 1.1 This procedure uses techniques described in EPA Method 3550C for extracting nonvolatile and semi-volatile organic compounds from solids such as soil, sediment, sludge, waste, and tissue.
- 1.2 This method is applicable to the isolation and concentration of water insoluble and slightly water soluble organics in preparation for a variety of chromatographic procedures. The low concentration method (individual components of <20 mg/Kg) uses a larger sample size and a more rigorous extraction procedure.
- 1.3 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DoD ELAP. QC requirements defined in the SOP *Department of Defense Projects - Laboratory Practices and Project Management*, may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 A sample is mixed with anhydrous sodium sulfate to form a free flowing powder. The sample is solvent extracted three times using ultrasonic extraction. The ultrasonic process ensures intimate contact of the sample matrix with the extraction solvent. The solvents used for extraction and concentration are dependent on the analysis being performed. A portion of the extract is removed for cleanup and/or analysis.
- 2.2 It is highly recommended that the extracts be cleaned up prior to analysis. Refer to appropriate cleanup and methods SOPs.

## 3) Definitions

- 3.1 For laboratory definitions applicable to most analyses, refer to the SOP for *Sample Batches* (ADM-BATCH).

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. The department supervisor/manager or designee performs final review and sign-off of the data.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency, as described in the *Employee Training and Orientation* (ADM-TRAIN).

## 5) Interferences

- 5.1 Phthalate esters can pose difficulties when performing sample extractions for organochlorine pesticides, PCBs, and other semi-volatile organics. Phthalates

	STANDARD OPERATING PROCEDURE	Ultrasonic Extraction
	ALS   Environmental - Kelso	EXT-3550, Revision 15.0
		Effective 2/18/2021
		SOP Review: 2/11/2021
		Page 3 of 12

are easily extracted or leached from materials containing plastics during laboratory operations. Interferences from phthalates can best be minimized by avoiding contact with any plastic materials.

- 5.2 Contamination by carryover can occur whenever high-concentration and low-concentration samples are sequentially analyzed. All apparatus must be cleaned prior to use on individual samples.
- 5.3 Refer to SW-846 Method 3500 for additional discussion of interferences. Additional cleanup procedures are described in the applicable ALS SOP.

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.
- 6.2 This method uses Dichloromethane, a known human carcinogen. Viton brand gloves should be used while rinsing, pouring or transferring the solvent.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Refer to the applicable section in the determinative SOP (see Table 1) and method for sample collection, preservation, and holding times. Also, refer to the introductory material in SW-846, Organic Analysis, -Section 4.

## 8) Standards, Reagents, and Consumable Materials

- 8.1 Pesticide grade inorganic chemicals shall be used in all tests. Other grades may be used, provided it is first confirmed that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination or introducing interferences.
- 8.2 Organic-free reagent water. This may be deionized water or tap water if it has been determined to be free of interferences and trace levels or target analytes.
- 8.3 Sodium sulfate (anhydrous),  $\text{Na}_2\text{SO}_4$ . Purify by heating at  $400^\circ\text{C}$  for 4 hours in a shallow tray or crucible, or by pre-cleaning the sodium sulfate with methylene chloride. If the sodium sulfate is pre-cleaned with methylene chloride, a method blank must be analyzed, demonstrating that there is no interference from the sodium sulfate.
- 8.4 Extraction solvents.
  - 8.4.1 Low concentration soil/sediment and aqueous sludge samples shall be extracted using a solvent system that gives optimum, reproducible recovery for the matrix/analyte combination to be measured.
  - 8.4.2 Methylene chloride:Acetone,  $\text{CH}_2\text{Cl}_2:\text{CH}_3\text{COCH}_3$  (1:1, v:v). Pesticide quality or equivalent. Other solvent ratios can be used if acceptable method performance is demonstrated.
  - 8.4.3 Methylene chloride,  $\text{CH}_2\text{Cl}_2$ . Pesticide quality or equivalent.
  - 8.4.4 Hexane,  $\text{C}_6\text{H}_{14}$ . Pesticide quality or equivalent.
- 8.5 Exchange solvents.

		Page 4 of 12

8.5.1 Hexane, C<sub>6</sub>H<sub>14</sub>. Pesticide quality or equivalent.

## 9) Apparatus and Equipment

9.1 Ultrasonic preparation - A horn type device equipped with a titanium tip, or a device that will give equivalent performance, shall be used. The horn should be tuned prior to sample extraction. (See Attached Tuning Procedure - Appendix A) Ultrasonic Disrupter - The disrupter must have a minimum power wattage of 300 watts, with pulsing capability. A device designed to reduce the cavitation sound is recommended. Follow the manufacturer's instructions for preparing the disrupter for extraction of samples with low and medium/high concentration. Use a 3/4" horn for the low concentration method and a 1/8" tapered microtip attached to a 1/2" horn for the medium/high concentration method.

9.2 Ultrasonic Disrupter - The disrupter must have a minimum power wattage of 300 watts, with pulsing capability. A device designed to reduce the cavitation sound is recommended. Follow the manufacturer's instructions for preparing the disrupter for extraction of samples with low and medium/high concentration. Use a 3/4" horn for the low concentration method and a 1/8" tapered microtip attached to a 1/2" horn for the medium/high concentration method.

9.3 Sonabox - Recommended with above disrupters for decreasing cavitation sound (Heat Systems - Ultrasonics, Inc., Model 432B or equivalent).

9.4 Pasteur glass pipettes - 1 mL and 5 mL disposable.

9.5 Beakers - 250 or 400 mL.

9.6 Vacuum filtration apparatus.

9.7 Drying funnel - modified funnel with Pyrex glass wool at bottom.

**NOTE:** Fritted glass discs are difficult to decontaminate after highly contaminated extracts have been passed through. Columns without frits may be purchased. Use a small pad of Pyrex glass wool to retain the adsorbent. Prewash the glass wool pad with elution solvent prior to packing the column with adsorbent.

9.8 Kuderna-Danish (K-D) apparatus.

9.8.1 Concentrator tube - 10 mL, graduated (Kontes K-570050-1025 or equivalent). A ground glass stopper is used to prevent evaporation of extracts.

9.8.2 Evaporation flask - 500 mL (Kontes K-570001-500 or equivalent). Attach to concentrator tube with springs, clamps, or equivalent.

9.8.3 Snyder column - Three ball macro (Kontes K-503000-0121 or equivalent).

9.8.4 Springs or clips for attaching concentrator tubes.

9.8.5 Boiling chips - Pre-cleaned by rinsing with DCM, approximately 10/40 mesh (silicon carbide or equivalent).

9.8.6 Water bath - Heated, with concentric ring cover, capable of temperature control ( $\pm 5^{\circ}\text{C}$ ). The bath should be used in a hood.

9.8.7 Balance - Top loading, capable of accurately weighing to the nearest 0.001 g.

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Ultrasonic Extraction
	EXT-3550, Revision 15.0
	Effective 2/18/2021
	SOP Review: 2/11/2021
	Page 5 of 12

- 9.8.8 Vials - 2 mL, for GC autosampler, with Teflon lined screw caps or crimp tops.
- 9.8.9 Glass vials - 40 mL, with Teflon lined screw caps.
- 9.8.10 Spatula - Stainless steel or Teflon.
- 9.8.11 Syringes - appropriate size for QC spiking.
- 9.9 Ultrasonic Bath- Have large transducer areas and tanks that produce a high-powered ultrasonic intensity throughout the entire oscillating tank. Constant power and automatic frequency control ensure optimum distribution of ultrasonic energy and reproducible results.

## 10) Preventative Maintenance

- 10.1 Routine cleaning of the extraction apparatus is necessary, including all parts exposed to contact with samples, especially ultrasonic horn cells.
- 10.2 The ultrasonic horn must be tuned prior to use. Proper operation of the horn is critical in achieving good method performance. Refer to the manufacturer's specifications in Appendix A.

## 11) Procedure

- 11.1 All extraction and sample information is recorded on the applicable bench sheet.
- 11.2 Sample aliquots are prepared by the appropriate groups according to the SOPs: SOILPREP-ALIQUOT and SOILPREP-SUBS.
- 11.3 In certain cases, sample results are desired based on dry weight basis. Refer to the SOP for *Total Solids* (SOILPREP-SOLIDS). If the determination is performed by the organics preparation personnel, a portion of the sample for this determination should be weighed out at the same time as the portion used for analytical determination.
- 11.4 Nonporous or wet samples (gummy or clay type) that do not have a free flowing sandy texture must be mixed with anhydrous sodium sulfate to facilitate drying, using a spatula. After addition of sodium sulfate, the sample should be free flowing.
- 11.5 Add amount of surrogate standards specified on the appropriate benchsheet referenced in Section 19.7 to all samples, spikes, standards, and blanks. For the LCS and sample(s) in each analytical batch selected for matrix spiking, add the specified amount of matrix spike standard as specified on the appropriate benchsheet referenced in Section 19.7.
- 11.6 Extraction method for samples by sonic horn:
  - 11.6.1 Immediately add enough extraction solvent specified on the appropriate benchsheet referenced in Section 19.7 to cover the sample by one inch.
  - 11.6.2 Place the bottom surface of the tip of the disrupter horn about 1/2 in. below the surface of the solvent, but above the sediment layer. Addition of a small amount of extraction solvent may be needed to ensure proper horn operation.
  - 11.6.3 Extract for 3 minutes. Sonifier settings are Output of 4, Duty Cycle of 70%. Branson settings are Amplitude 80%, Pulse On 1.5 seconds, Pulse Off 1.5 seconds.

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Ultrasonic Extraction

	SOP Review: 2/11/2021
	Page 6 of 12

- 11.6.4 Assemble a Kuderna-Danish (K-D) concentrator by attaching a 10 mL concentrator tube to a 500 mL evaporator flask.
- 11.6.5 Decant and filter extracts into a K-D apparatus using vacuum filtration and a modified funnel, covering the glass wool with sodium sulfate.
- 11.6.6 Repeat the extraction two or more times with two additional 100 mL (or more if needed) portions of solvent. Decant off the solvent into the K-D apparatus through the modified funnel after each ultrasonic extraction. On the final ultrasonic extraction, pour the entire sample into the modified funnel and rinse with extraction solvent. Rinse 3 times with DCM.
- 11.6.7 Add one to two clean boiling chips to the evaporation flask and attach a three ball Snyder column. Place the K-D apparatus on the S-Evap so that the concentrator tube is partially immersed in the hot water bath (70-75°C) and the entire lower rounded surface of the flask is bathed with hot vapor. Adjust the vertical position of the apparatus and the water temperature, as required, to complete the concentration in 10-15 minutes. At the proper rate of distillation the balls of the column will actively chatter, but the chambers will not flood with condensed solvent. When the apparent volume of liquid reaches 5 mL, remove the K-D apparatus and allow it to drain and cool for at least 10 minutes.
- 11.6.8 If a solvent exchange is required on the S-Evap, add ~15 mL of the exchange solvent through the Snyder column. This solvent exchange should be performed in a hood with the extract near room temperature. Concentrate the extract by raising the temperature of the water bath, if necessary, to maintain proper distillation. When the apparent volume again reaches 10 mL, remove the K-D apparatus and allow it to drain and cool for at least 10 minutes.
- 11.6.9 Remove the Snyder column and rinse the flask and its lower joints into the concentrator tube with 10 mL of methylene chloride or exchange solvent. If sulfur crystals are a problem, proceed to Method 3660 for cleanup. The extract may be further concentrated by using the nitrogen blowdown technique or adjusted to 10.0 mL with the solvent last used.
- 11.6.10 Nitrogen Blowdown Technique
- 11.6.10.1 Place the concentrator tube in N-evap and evaporate the solvent volume to the required level using a gentle stream of clean, dry nitrogen (filtered through a column of activated carbon).
- CAUTION:** Do not use plasticized tubing between the carbon trap and the sample.
- 11.6.10.2 A solvent exchange may be performed at this step by rinsing with the appropriate exchange solvent. During evaporation, the solvent level in the tube must be positioned to prevent water from condensing into the sample. The volume of extract in the tube must be monitored during blowdown to avoid loss of more volatile analytes. Under normal operating conditions, the extract should not be allowed to become dry.
- CAUTION:** When the volume of solvent is reduced below 1 mL, semi-volatile analytes may be lost.
- 11.6.11 Bring the extract to the prescribed final volume and transfer the concentrated extract to the appropriate labeled autosampler vial or storage vial. The extracts

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Ultrasonic Extraction
	EXT-3550, Revision 15.0
	Effective 2/18/2021
	SOP Review: 2/11/2021
	Page 7 of 12

obtained may now be analyzed for the target analytes using the appropriate determinative technique.

11.7 Extraction method for samples by sonic bath for 1,4-Dioxane.

11.7.1 Add exactly 10 mL of methylene chloride to each sample and seal with a VOA vial cap. If 10 mL will not adequately cover the sample, add 20 mL of DCM (final volume will need to be adjusted later to achieve a 10 mL true final volume). Mark the meniscus.

11.7.2 Place the VOA vials in a sonic bath and sonicate for 30 minutes. Make sure the water level in the bath is above or at least level with the solvent in the VOA vials to ensure proper extraction.

11.7.3 After extraction, pull off exactly 1 mL and place into a labeled autosampler vial for analysis. The extracts obtained may now be analyzed for the target analytes using the appropriate determinative technique.

11.7.3.1 It may be necessary to centrifuge the sample and/or filter the extract into the vial to remove soil particles from the extract. If necessary, filter about 2 mL of extract through a 0.45  $\mu$ m filter on a disposable syringe and place exactly 1 mL of the filtered extract into a vial for analysis for a True Final Volume of 10 mL. If a higher initial volume was required, pull off the appropriate volume and concentrate to 1 mL on the N-Evap under a gentle stream of nitrogen with the temperature <35°C to achieve a True Final Volume of 10 mL.

## 12) QA/QC Requirements

12.1 Refer to the SOP for the determinative method and SOP for *Sample Batches* (ADM\_BATCH) for minimum QC requirements. Project-specific batching protocols may also be required.

12.2 The QC solutions required by the method must be added as described in the analytical method. The amount and identification of QC solutions added must be documented on the bench sheet. Any reagent blanks, laboratory control samples, or matrix spike samples should be subjected to exactly the same analytical procedures as those used on actual samples.

## 13) Data Reduction and Reporting

13.1 Preparation of all samples must be documented on a bench sheet. All information regarding the sample(s) extracted, aliquoted, QC spiked, extraction steps performed, etc. must be documented by the person(s) performing the extraction.

13.2 The bench sheet must be reviewed by the extraction lead, supervisor, or instrument lab analyst. The instrument lab analyst should sign-off on the bench sheet, thus accepting custody of the extracts.

## 14) Method Performance

14.1 Available method performance data is given in the reference method. In addition, this procedure was validated through single laboratory studies of accuracy and precision as specified in the determinative procedures.

	ALS   Environmental - Kelso	EXT-3550, Revision 15.0
		Effective 2/18/2021
		SOP Review: 2/11/2021
		Page 8 of 12

## 15) Pollution Prevention and Waste Management

- 15.1 The laboratory will comply with all Federal, State and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.
- 15.2 All extracted soil samples are collected in a labeled waste container for disposal in accordance with applicable state and federal regulations governing waste management.

## 16) Contingencies for Handling Our-of-Control or Unacceptable Data

- 16.1 Refer to the SOP for *Non Conformance and Corrective Action*, for procedures for corrective action.
- 16.2 Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

## 17) Training

- 17.1 All analysts performing this analysis are required to read and understand this SOP.
- 17.2 Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

## 18) Method Modification

- 18.1 There are no known modifications in this laboratory standard operating procedure from the reference method.

## Appendix A Sonic Horn Tuning Procedures

### 1. Tekmar Model 501:

Tuning optimizes performance and insures maximum transfer of energy by matching the frequency of the power supply to that of the converter/probe assembly. The power supply should be tuned 1) every time a new probe or accessory is used, 2) on occasions to compensate for the frequency variation caused by cavitation erosion, 3) following 10 minutes of continuous operation and 4) when the sample temperature is significantly higher or lower than room temperature.

The piezoelectric crystal within the converter is part of the circuitry which control s the frequency at 20 kHz. Any changes in the crystal's capacitance resulting from a variation in temperature will cause the equipment to operate in an out-of-tune condition. For reliable performance and equipment protection, it is important that the unit be tuned after the probe temperature has had a chance to stabilize. When relocating the Ultrasonic Processor from a very cold or very hot environment, allow 30 minutes for the unit to stabilize before operating. Continuous operation causes temperature elevation in the sample. This increase in temperature is transmitted through the probe to the crystal assembly. Always tune the power supply after the probe has reached operating temperatures. When working with low or high temperature samples, immerse the probe in the sample for a few minutes, withdraw the probe from the sample, then tune the power supply.

**IMPORTANT:** *Tuning must be performed in air with the probe out of the sample. While tuning, do not allow the probe to contact anything.*

To tune the power supply, proceed as follows:

- 1.1. Ensure that the probe or microtip is not immersed in the sample and that it does not come in contact with anything. If a cup horn is used, make sure that the water has been drained out of it. If a flow through cell is used, make sure that the sample has been drained out of it.
- 1.2. Set PULSER to OFF.
- 1.3. Set AMPLITUDE control to "100" (to "40" when using a microtip).

**CAUTION:** When tuning a microtip, never allow vibration in air for more than 10 seconds. With a microtip, never allow the AMPLITUDE control to be set above the microtip limit "40". Ignoring these instructions will cause the microtip to fracture.

- 1.4. Set ON/OFF power switch to ON. The switch will illuminate.
- 1.5. Depress the TUNE switch and rotate the TUNER clockwise or counterclockwise until a minimum (not maximum) reading (usually less than 20) is obtained on the POWER MONITOR. If the minimum reading cannot be obtained, the probe, cup horn, tip, microtip, extender, or accessory is loose or out of resonance, or the power supply or converter require servicing. A loose probe will usually generate a loud, piercing sound.

NOTE:

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Ultrasonic Extraction
	EXT-3550, Revision 15.0
	Effective 2/18/2021
	SOP Review: 2/11/2021
	Page 12 of 12

- The probe is tuned to vibrate at a specific frequency – 20 kHz  $\pm$ 50 Hz. If the resonant frequency of the probe has changed, due to cavitation erosion or fracturing, minimum reading will not be obtained. If minimum reading cannot be obtained, check the instrument without the probe to determine which component might be defective. If proper tuning is obtained using the converter without the probe, the probe is defective and should be changed.
  - A loose probe will usually generate a loud piercing sound.
  - Since the amplitude required is application dependent and subject to the volume and composition of the sample, it is recommended that the amplitude be first set at mid-range, then empirically determined and optimized while the samples is being processed.
- 1.6. Set the AMPLITUDE control to “20” when working with a microtip, and “50” when working with any other probe or accessory.
- 1.7. With a dual output 600 watt Ultrasonic Processor, if two converters are going to be used simultaneously, connect at this time the second converter cable to the right converter connector.
2. Branson Model 450:
- 2.1. To determine if the equipment is operating properly, proceed as follows:
- Mount ½” disruptor horn (with flat tip if tapped) to converter.
  - Set Output Control to 5, Timer to HOLD and ON/OFF switch to ON.
  - Record meter reading with horn in air
    - Meter Reading\_\_\_\_\_
    - Horn Size\_\_\_\_\_
  - Fill 500 mL Pyrex beaker to 500 mL level with room temperature tap water.
  - Immerse horn tip halfway to 250 mL mark. Set ON/OFF switch to On and record reading.
    - Meter Reading\_\_\_\_\_

Perform this test and compare readings periodically to ensure that the equipment is operating satisfactorily. A variation of 10 between the first and second readings is acceptable. If readings are not within tolerance, refer to Trouble Analysis Chart, section 5.

## EXTRACTION METHOD FOR ORGANOTINS IN SEDIMENT, WATER AND TISSUE

DOCUMENT ID: EXT-OSWT, REV 12.0

Prepared By:   
Extractions Manager, Jonathon Walter

Date: 12/1/2020

Prepared By:   
Quality Assurance Manager, Kurt Clarkson

Date: 12/1/2020

Approved By:   
Laboratory Director, Charles (Pat) Byrne

Date: 12-1-20

## 1) Scope & Applicability

- 1.1 This procedure is used to extract selected butyltins from sediments, water and tissues. The procedure is a preparative step for determination of butyltins by gas chromatography (SOP SOC-BUTYL). The procedure can also be applied to porewater samples.
- 1.2 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DOD ELAP. QC requirements defined in the SOP *Department of Defense Projects – Laboratory Practices and Project Management* (ADM-DOD/ADM-DOD5) may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 Butyltin compounds are extracted with an organic solvent using the technique suitable for the sample matrix. Sediment and tissue samples are extracted by tumbling. Water samples are extracted by liquid-liquid extraction. Extracts are then derivitized to their hexyl form using hexylmagnesiumbromide. After derivitization, extracts from sediment and water samples are cleaned up with silica and alumina; tissue sample extracts are cleaned up with Florisil. Extracts are then taken to final volume and analyzed by GC/FPD.

## 3) Definitions

- 3.1 For environmental laboratory quality definitions, guidance on analytical calibration and sample batches, refer to the SOP for Sample Batches, ADM-BATCH.

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. Final review and sign-off of the data is performed by the department supervisor/manager or designee.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency.

## 5) Interferences

- 5.1 Solvents, reagents, glassware, and other sample processing hardware may yield discrete artifacts and/or elevated baselines, causing misinterpretation of the chromatograms. All of these materials must be demonstrated to be free from interferences, under the conditions of the analysis, by running blanks

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Refer to the applicable section in the analytical and/or extraction SOP for collection, preservation, and holding times.

## 8) Standards, Reagents, and Consumable Materials

- 8.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Standards, reagents and consumable material documentation shall indicate traceability to purchased reagents or compounds. Refer to the SOP *Reagent/Standards Login and Tracking* (ADM-RTL) for the complete procedure and documentation requirements.
- 8.2 All stocks, working solutions and sample dilutions should be prepared using deionized water (DI) conforming to ASTM Type I or ASTM Type II reagent water. For more information on reagent water generation, refer to the related SOP, Operation and Maintenance of Laboratory Reagent Water Systems.
- 8.3 Solvents: Dichloromethane (DCM), hexane, pentane, methanol, and anhydrous diethyl ether (J.T. Baker).
- 8.4 Tropolone in dichloromethane (DCM) - 0.1% (w/v) solution is prepared by adding 1 g tropolone per liter of DCM.
- 8.5 Tropolone in hexane - 0.1% (w/v) solution is prepared by adding 1 g tropolone per liter of hexane.
- 8.6 Tropolone in water - 0.01% (w/v) solution is prepared by adding 0.4 g tropolone and 40 mL concentrated HCl to 4 L of reagent water.
- 8.7 Reagent water
- 8.8 D.I. Water
- 8.9 Sodium sulfate, Granular
- 8.10 Concentrated HCl.
- 8.11 Fisher PrepSepR® 1 g silica cartridges, or equivalent.
- 8.12 Fisher PrepSepR® 1 g alumina cartridges, or equivalent.
- 8.13 Magnesium turnings (from Fisher). It is recommended to investigate the use of semiconductor grade magnesium if blank contamination (tin) is exhibited.
- 8.14 Bromohexane (from Fluka).
- 8.15 Florisil cartridges (CPI).
- 8.16 Surrogate and spiking solutions--see SOP SOC-BUTYL.
- 8.17 Hexylmagnesiumbromide -  $\text{CH}_3(\text{CH}_2)_5\text{MgBr}$  (Grignard). Prepare as follows:

- 8.17.1 All glassware used in Grignard preparation is baked at least 4 hours at  $\geq 100^{\circ}\text{C}$  to remove water. Glassware is assembled while still warm.
- 8.17.2 Add 14 g of magnesium to the three necked flask during assembly. The condenser is placed in the middle neck of the flask with a drying tube at the top of the condenser. A glass stopper is put in one neck of the flask, with the 125 mL addition funnel in the last flask opening. The addition funnel contains 38 mL bromohexane in 95 mL anhydrous ether, and is topped with a drying tube.
- 8.17.3 Add 4 mL bromohexane and 10 mL ether to the flask. A glass rod is used to crush 2 or 3 Mg chips. A hot water bath may be used to help reaction start. After reaction has started, hot water bath is removed.
- 8.17.4 Once reaction is started, the bromohexane solution in the addition funnel is added at a rate of about 3 drops per second. Once nearly all of the bromohexane/ether solution has been added, an additional 95 mL of anhydrous ether and 38 mL of bromohexane are added to the addition funnel (in that order). Once all bromohexane solution has been added, the hot water bath is returned and reaction is refluxed for at least one hour. Grignard solution is now ready to use.
- 8.17.5 Grignard has a 6 month expiration from time of preparation. Due to the reactive nature of Grignard reagent, it should be checked for reactivity prior to continued use. A derivatization blank, a 1 ppm standard, and a 10 ppm standard are typically prepared ahead of sample derivatization to assure the purity and reactivity of each batch of Grignard.
- 8.18 Acetone solution of dimethyldioxirane (DMD) – Dimethyldioxirane (DMD) is synthesized from acetone by reacting it with sodium monoperoxysulfate in a chilled water solution at a pH of between 7 and 8. An acetone solution of DMD is distilled from the resultant mixture under a mild vacuum and collected with the assistance of a dry ice-solvent bath. Refer to Appendix A for details of preparation of DMD.

## 9) Apparatus and Equipment

- 9.1 Materials used in sediment, tissue and water extractions.
- 9.2 pH paper, 0 - 14 range
- 9.3 16 x 150 mm and 25 x 150 mm disposable glass culture tubes with Teflon lined screw caps
- 9.4 0.5 mL, 1 mL, 2 mL, 5 mL, and 10 mL serological pipettes
- 9.5 Pasteur pipettes
- 9.6 2 mL glass vials with Teflon lined crimp-top caps
- 9.7 Nitrogen evaporator
- 9.8 Centrifuge - capable of handling glassware in 7.1.2.
- 9.9 Vacuum pump and manifold
- 9.10 Kuderna-Danish (K-D) apparatus

- 9.10.1 Concentrator tube - 10 mL, graduated.
- 9.10.2 Evaporation flask - 250 mL. Attach to concentrator tube with springs, clamps or equivalent.
- 9.10.3 Three-ball Snyder column.
- 9.10.4 Springs - 1/2 inch.
- 9.10.5 Boiling chips - Pre-cleaned via Soxhlet extraction, approximately 10/40
- 9.10.6 Mesh (silicon carbide or equivalent).
- 9.10.7 Water bath - Heated, with concentric ring cover, capable of temperature
- 9.10.8 Control ( $\pm 5^{\circ}\text{C}$ ). The bath should be used in a hood.
- 9.11 Materials for extraction of sediments
  - 9.11.1 250 mL Teflon bottles with Teflon screw caps
  - 9.11.2 Tumbler, capable of holding twelve 250 mL Teflon bottles
  - 9.11.3 Modified vacuum filtration funnel
  - 9.11.4 Whatman No. 41 filter paper
  - 9.11.5 Polypropylene funnels
  - 9.11.6 Scoopulas
  - 9.11.7 400 mL beakers
- 9.12 Materials for extraction of waters
  - 9.12.1 Continuous liquid/liquid extraction body
  - 9.12.2 500 mL round bottom flask, with green Keck clip
  - 9.12.3 1000 mL graduated cylinder
  - 9.12.4 Stir rod and pH paper
  - 9.12.5 Allihn condensor
- 9.13 Porewater sample preparation
  - 9.13.1 Polycarbonate centrifuge bottles, 1 L.
  - 9.13.2 Water-from-sand apparatus

- 9.13.3 Large spoon
- 9.13.4 Nitrogen Hood
- 9.13.5 Refrigerated Centrifuge capable of handling 1 L bottles
- 9.14 Materials for extraction of tissues
  - 9.14.1 Vortex for VOA vials
  - 9.14.2 Tumbler for VOA vials
  - 9.14.3 40 mL and 60 mL VOA vials with Teflon lined septa and screw caps
- 9.15 Materials for Grignard preparation
  - 9.15.1 500 mL round bottom three necked flask with glass stoppers
  - 9.15.2 30 cm condenser
  - 9.15.3 125 mL addition funnel
  - 9.15.4 Two drying tubes filled with drierite® and plugged with glass wool
  - 9.15.5 Glass rod
  - 9.15.6 Hot water bath
  - 9.15.7 100 mL graduated cylinders
  - 9.15.8 150 mL glass beaker.

## 10) Preventative Maintenance

- 10.1 All maintenance activities are recorded in a maintenance logbook kept for each instrument. Pertinent information (serial numbers, instrument I.D., etc.) must be in the logbook. This includes the routine maintenance described herein. The entry in the log must include: date of event, the initials of who performed the work, and a reference to analytical control.

## 11) Procedure

- 11.1 Extraction of Organotins from Sediments
  - 11.1.1 Refer to the SOPs Aliquoting of Samples (SOILPREP-ALIQUOT) and Subsampling and Compositing of Samples (SOILPREP-SUBS) for sample aliquoting. If sufficient holding time permits, air dry the sample in the hood. Acidify with 2 mL concentrated HCl and mix the sample thoroughly. Mix samples with adequate sodium sulfate to dry sample. The method blank and laboratory control sample are made from an equal amount of sodium sulfate. Add sample to a 0.1% tropolone rinsed 250 mL Teflon bottle and add appropriate surrogate and spike. Add more acid if

necessary. Add enough 0.1% tropolone/DCM solution to cover sample with at least 1/2" of solvent (approximately 150 mL).

- 11.1.2 Wrap Teflon tape around threads of bottle. Pinch bottle in center and cap. If the bottle does not stay pinched then remove cap, add more Teflon tape and pinch and cap again. If the bottles stay pinched then they are sealed completely and won't leak on the tumbler. Tumble the sample(s) for 16-24 hours.
  - 11.1.3 Pour the sample into a modified funnel with glass wool and sulfate that is unbaked. Filter by vacuum into a 250 mL KD flask. Evaporate the extract on a water bath (75°C) to approximately 10-20 mL. Add approximately 10-20 mL hexane while on the S-EVAP and allow DCM to evaporate until only hexane remains.
  - 11.1.4 Using the N-Evap, concentrate the extract to approximately 3 mL. Add 2 mL of reagent water and vortex. Centrifuge to separate precipitates. Using a Pasteur pipet and pentane, quantitatively transfer the extract (solvent) layer to a 2nd culture tube. Evaporate extract down to approximately 2 mL.
  - 11.1.5 Add 2 mL of Grignard reagent to the culture tube and vortex on a table top vortexer for 45 minutes. Place the test tubes in an ice bath and add concentrated HCL slowly (dropwise) until there is no reaction. Then while vortexing (hand vortexer) add, in turn, 1 mL HCL, 1 mL DI Water, 1 mL HCL, 1 mL DI Water then finish with 1 mL HCL..
  - 11.1.6 Transfer the top (clear) hexane layer to a new test tube. On an N-Evap concentrate to 1-2 mL. Take the extract to a 4 mL final volume and remove 1 mL for cleanup. Add 1 mL DMD to this aliquot, vortex 3 minutes. Solvent exchange to hexane then add a small amount of unbaked granular sulfate to remove any water left behind by the DMD.
  - 11.1.7 Using the vacuum or positive pressure manifold, set up alumina/silica cartridges and condition with 5 mL hexane. Discard hexane. Place samples in cartridges and bring down to almost dry, and elute with 6 mL of pentane, allowing this to go dry. Take extracts to a 1.0 mL final volume in hexane, and place in a 2 mL vial.
- 11.2 Extraction of Porewater from sediments
- 11.2.1 All labware must be rinsed with 10% HCl followed by DI water prior to use. Labware must be dry prior to further rinsing. Air drying is best for polycarbonate labware; methanol may be used if time is limited. All polycarbonate labware must be rinsed with 0.1% w/v tropolone in hexane followed by hexane; all other labware must be rinsed with 0.1% w/v tropolone in Dichloromethane followed by Dichloromethane.
  - 11.2.2 Very sandy sediments often do not yield sufficient volumes of water. For the samples, it will be necessary to employ at least two water-from-sand recovery apparatuses; make a note of this as these samples will be exposed to the atmosphere.

- 11.2.3 Use 1000 mL of reagent water for the method blank and centrifuge along with the samples.
  - 11.2.4 Centrifuge the balanced bottles opposite each other for 30 minutes at 1000 -3000 G. (1100-3250 RPM for a 10 inch rotor radius).
  - 11.2.5 Decant the water into clean polycarbonate centrifuge bottles and balance as above.
  - 11.2.6 Centrifuge the samples a second time at 3000 G.
  - 11.2.7 Decant the water from the centrifuge bottles into polycarbonate sample bottles. If the sediment is re-suspended during the decantation, the samples must be centrifuged again before decanting.
  - 11.2.8 Add 0.5-1 mL of concentrated hydrochloric acid to each sample bottle to preserve them and store at or below 4°C.
  - 11.2.9 Some projects may require samples to be filtered prior to preservation and storage. Check project specific requirements to see when filtration is necessary. Samples must be filtered using 0.4 µm polycarbonate filters in porcelain Buchner funnels. The samples are filtered into polycarbonate Erlenmeyer flasks.
  - 11.2.10 Extract the recovered porewater following the procedure in section 11.3.
- 11.3 Extraction of Organotins from Water
- 11.3.1 Rinse all labware once with 0.1% hydrochloric acid (HCl), then deionized water, then acetone. Next rinse once with 0.1% tropolone in DCM followed two times with DCM.
  - 11.3.2 Refer to the SOP for *Continuous Liquid-Liquid Extraction* (SOP EXT-3520). Add 500 mL of DCM to the extractor. Measure and transfer 500 mL of sample to the extractor. Set up the method blank, laboratory control sample, and spike the samples, using 500 mL DI Water. Add surrogate and matrix spikes as appropriate.
  - 11.3.3 Add 500 mL of 100 ppm tropolone in 0.1% HCl in reagent water. Follow the instructions for continuous liquid-liquid extraction.  
  
**Note:** For porewater samples, the available sample volume is typically limited to 500 mL or less. Determine the amount of sample available and adjust the volume extracted accordingly. Adjust the amount of reagents and surrogate and matrix spike amounts accordingly.
  - 11.3.4 Make sure that the continuous liquid - liquid extractor is receiving adequate flow for cooling, and that the units are cycling properly. Check the chiller for proper temperature and operation. (Condensers should be cold to the touch before extraction begins).

- 11.3.5 Cycle the unit for 18-24 hours.
- 11.3.6 Transfer the extract (DCM) to a 250 mL KD flask. Evaporate the extract on a water bath (<75°C) to approximately 20 mL. Add approximately 10 mL hexane, allow to S-Evap until all the DCM has been removed.
- 11.3.7 Transfer the extract to a culture tube and, using the N-Evap, blow down the extract to approximately 2 mL.
- 11.3.8 Add 2 mL Grignard, and vortex every 5 minutes over a 45 minute period. Add concentrated HCl slowly, vortexing as needed, until there is no reaction and hexane layer is clear.
- 11.3.9 Clean up using alumina and silica cartridge as described in section 11.1.6 and take to 1.0 mL (nominal) final volume.
- 11.4 Extraction of Organotins from Tissue
  - 11.4.1 Mix sample thoroughly and weigh approximately 10 g into a 40 mL VOA vial. Add surrogate and matrix spikes. Acidify with 10mL of 1.5M HCl. Add 10mL of 0.1% tropolone/DCM. Tumble for 1 hour. Centrifuge the extract and transfer tropolone/DCM layer to a culture tube. Repeat two more times with addition of tropolone/DCM each time. Add about 2g of unbaked granular sulfate to remove any remaining water.
  - 11.4.2 Evaporate the extract to 5 mL on the N-evap. Transfer extract off of the sulfate and transfer to a 15 mL culture tube. Add approximately 1 mL of hexane, evaporate to 2 mL, add 10 mL more hexane, evaporate to 2 mL and repeat the addition of hexane two more times.
  - 11.4.3 Continue with Grignard derivitization and take to final volume using a 6g Florisil and silica gel cartridge. Using the vacuum manifold, set up the Florisil/Silica gel cartridges and condition with 5 mL of Hexane. Discard Hexane. Place samples in cartridges and bring down to almost dry, and elute with 10 mL of Pentane. Discard this 10 mL fraction and elute with an additional 10 mL of Pentane. Take the second 10 mL fraction to a 1.0 mL final volume in Hexane, and place in a 2 mL vial.

## 12) QA/QC Requirements

- 12.1 This procedure shall operate under the formal Quality Assurance Program established at ALS and must maintain records that define the quality of data that is generated. Data shall be compared to established criteria in order to determine if the results of the analyses meet the performance characteristics of the method.
- 12.2 All measurements are to be recorded in the applicable logbook or benchsheets as described above. Entries into logbooks are to be performed in accordance with the *SOP for Making Entries Onto Analytical Records*.
- 12.3 The QC samples required for the extraction batch is described in the *Butyltins* SOP (SOC-BUTYL) and the SOP for *Sample Batches* (ADM-BATCH). Any method blanks

or laboratory control samples should be subjected to exactly the same procedures as those used in actual samples.

- 12.4 Follow the applicable quality control guidelines outlined in *Butyltins* SOP (SOC-BUTYL).
- 12.5 The laboratory must follow all quality control requirements outlined in Appendix F of the *DoD Quality Systems Manual for Environmental Laboratories* (current version) for samples submitted for DoD ELAP projects. See the current version of *Department of Defense Projects Laboratory Practices and Project Management*.

### 13) Data Reduction and Reporting

#### 13.1 Data Review

- 13.1.1 Following primary data interpretation and calculations, all data is reviewed by a secondary analyst. Following generation of the report, the report is also reviewed. Refer to the *SOP for Laboratory Data Review Process (ADM-DREV)* for details. The person responsible for final review of the data report and/or data package should assess the overall validity and quality of the results and provide any appropriate comments and information to the Project Manager for inclusion in the report narrative.
- 13.1.2 It is the analyst's responsibility to review analytical data to ensure that all quality control requirements have been met for each sample batch or analytical run.

### 14) Contingencies for Handling Out-of-Control or Unacceptable Data

- 14.1 Refer to the SOP for *Non Conformance and Corrective Action* for procedures for corrective action. Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

### 15) Method Performance

- 15.1 Refer to the reference method for additional method performance data available.

### 16) Pollution Prevention and Waste Management

- 16.1 The laboratory will comply with all Federal, State and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.

### 17) Training

- 17.1 All analysts performing this analysis are required to read and understand this SOP.
- 17.2 Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

18) **Method Modifications**

- 18.1 There are no known modifications in this laboratory standard operating procedure from the reference method.

19) **References**

20) **Changes Since Last Revision**

Summary of Revision Changes			
Revision Number	Effective Date	Document Editor	Description of Changes
12.0	11/30/2020	T.Caron	Updated SOP signatories and ALS SOP formatting.

21) **Attachments, Tables, and Appendices**

- 21.1 DMD Preparation.

## Preparation of DMD

### 1) Standards, Reagents and Consumable Materials

- 1.1 Reagent grade acetone.
- 1.2 Reagent grade sodium bicarbonate
- 1.3 Oxone™ (sodium monoperoxysulfate mixture), from Aldrich.

### 2) Apparatus and Equipment

- 2.1 3 liter, 2-necked, round-bottomed reaction flask with PTFE stoppers
- 2.2 U-tube (i.d. 20-25 mm)
- 2.3 500 mL, 2-necked collection flask
- 2.4 250 mL graduated cylinder
- 2.5 150 mL beaker
- 2.6 Glass funnel
- 2.7 Vacuum pump with gauge
- 2.8 Magnetic stir plate with pear-shaped stir bar
- 2.9 Dry ice-acetone or dry ice-ethanol bath
- 2.10 Water ice-DI water bath
- 2.11 2 - 12 inch distillation columns
- 2.12 Aluminum foil

### 3) Procedure

- 3.1 Equip a 3 liter, 2-necked, round-bottomed reaction flask with an efficient magnetic stirrer. Attach the 12 inch distillation columns to the 500 mL 2-neck collection flask. A U-tube connects the reaction flask to the collection flask at one of the distillation columns. A vacuum pump hose is attached to the top of the second distillation column.
- 3.2 The collection flask must be chilled throughout synthesis and distillation to  $-78^{\circ}\text{C}$  by immersion in a dry ice-acetone bath (ethanol may be substituted for acetone in the dry ice bath).
- 3.3 While stirring, 250 mL Reagent water, 60 g reagent grade sodium bicarbonate and 250 mL reagent grade acetone are introduced into the reaction flask in that order. The reagent mixture is chilled to  $5-10^{\circ}\text{C}$  throughout reagent addition and DMD synthesis by immersing the bottom third of the reaction flask in an ice-DI water bath. The reaction flask mixture is stirred vigorously throughout reagent addition, synthesis and distillation.
- 3.4 120 g of Oxone™ is added to the reaction flask. The flask is then sealed.

- 3.5 Fifteen minutes following the addition of Oxone™, a vacuum of 80-100 Torr is applied, and the ice-DI water bath is removed. Be careful not to interrupt the stirring of the reaction mixture for longer than a few seconds, if at all, otherwise it is very difficult to start stirring again.
- 3.6 Encourage flow of the distillate toward the collection flask by loosening one of the stoppers on the reaction flask slightly. A small piece of aluminum foil may be used to maintain the gap between the stopper and the joint, if necessary. Distill for at least 2 hours. An acetone solution of DMD will accumulate in the chilled collection flask. Much of the DMD will accumulate as a white solid at the neck and bottom of the collection flask, and at the base of the distillation column.
- 3.7 After distillation is complete, turn vacuum pump off. Disconnect the vacuum pump from collection flask. Disconnect the U-tube from the distillation column and remove the distillation column and flask together. Allow the distillation column and flask to warm to around 0°C; any solid DMD will dissolve with swirling. Rinse the distillation column with a few mLs of reagent grade acetone, collecting the rinse with the distillate. About 120-150 mL of approximately 0.08M DMD in acetone, a very slightly yellow solution, should be recovered. The solution is transferred to clean, amber bottles, and stored at less than -10°C. Label containers with reagent ID and date of preparation.

		Page 2 of 12

## 1) Scope & Applicability

1.1 This procedure describes the Zero Headspace Extraction (ZHE) sample preparation by EPA Method 1311. The procedure applies to solid and liquid matrices as defined in method 1311. The preparation technique is used in determining leachable characteristics of volatile organic compounds from the sample.

## 2) Summary of Procedure

2.1 The sample is characterized as to its moisture content, size, physical state and miscibility in water (in cases of liquid samples). As needed, procedures are employed to physically reduce the sample size to accommodate the extraction device, to segregate liquid from solid matrices, and to separate biphasic mixtures of a liquid sample. The solid material is leached with twenty times its weight using a mildly acidic extraction fluid. Following extraction, the leachate is either analyzed for volatile organic compounds or, if an aqueous filtrate was collected prior to extraction, it is combined with the aqueous filtrate then analyzed for volatile organic compounds. Non-aqueous filtrates are stored for separate analysis, in which case the results are mathematically combined with those obtained from analysis of the leachate.

## 3) Definitions

3.1 For laboratory definitions applicable to most analyses, refer to the SOP for *Sample Batches* (ADM-BATCH).

## 4) Responsibilities

4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. Final review and sign-off of the data is performed by the department supervisor/manager or designee.

4.2 It is the responsibility of the department supervisor/manager to document analyst training. Documenting ongoing method proficiency is also the responsibility of the department supervisor/manager. Refer to *Employee Training and New Employee Orientation* (ADM-TRAIN).

## 5) Interferences

5.1 Some samples such as paints, thick oils or fine particulates may cause clogging of the filter device. These samples may require the use of a stainless steel filter disc in place of the standard glass fiber filter. The stainless steel filter disk cannot generally be adequately cleaned once it has been used for filtration of extremely difficult samples.

## 6) Safety

6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.

	STANDARD OPERATING PROCEDURE	ZHE
	ALS   Environmental – Kelso	EXT-ZHE, Rev. 1.0
		Effective 03/06/2019
		SOP Review: 2/12/2021
		Page 3 of 12

- 6.2 This method may use Methylene Chloride, a known human carcinogen. Viton brand gloves should be used while rinsing, pouring or transferring the solvent.
- 6.3 Sodium Hydroxide (NaOH) is a strong caustic and a severe health and contact hazard. Use nitrile or latex gloves while handling pellets or preparing solutions.
- 6.4 The procedure requires the use of a high-pressure nitrogen tank and pressurized apparatus. Care should be taken when moving cylinders and pressurizing the extraction device. Gas cylinders must be secured to a wall or an immovable counter with a double chain or a cylinder clamp at all times.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Samples should be collected (received) in glass jars with a minimum of headspace and care taken to minimize the loss of volatile analytes. Sample are collected in Teflon lined capped vials and stored at  $4 \pm 2^{\circ}\text{C}$  until analysis.
- 7.2 Holding Times: The ZHE extraction must be started within 14 days from sample collection. The ZHE extract must be analyzed within 14 days from the end of the ZHE extraction.

## 8) Standards, Reagents, and Consumable Materials

- 8.1 Compressed Gas: nitrogen is recommended
- 8.2 Glacial Acetic Acid: ACS reagent grade or equivalent.
- 8.3 Sodium Hydroxide: 1N, prepared from ACS reagent grade
- 8.4 Reagent Water: ASTM Type II or equivalent, free of volatile contaminants (laboratory deionized water meets these criteria)
- 8.5 Extraction Fluid (#1): Add 5.7 ml glacial acetic acid ( $\text{CH}_3\text{CH}_2\text{OOH}$ ) to 500 ml of reagent water; add 64.3 ml of 1N sodium hydroxide (NaOH); dilute to 1 liter. When correctly prepared the pH of this fluid will be  $4.93 \pm 0.05$ . Record date prepared and pH in the preparation log.
- 8.6 Glass Fiber Filter: effective pore size of 0.6 - 0.8  $\mu\text{m}$ .
- 8.7 Methanol: high purity, free of volatile contaminants
- 8.8 Stainless Steel Filter: manufactured and distributed by Associated Design and Manufacturing (Alexandria, VA) to be used as a substitute to the standard glass fiber filters and stainless steel filter support when filtering extremely viscous wastes such as thick oils or paint wastes.
- 8.9 Tedlar Bags
- 8.10 VOA Vials: 20 ml or 40 ml capacity, pre-preserved with HCl.

## 9) Apparatus and Equipment

- 9.1 Balance: accurate to within 0.1 gram
- 9.2 Beaker or Erlenmeyer flask (various sizes ranging from 100 mL to 500 mL)
- 9.3 Brushes or scouring pads: for cleaning of ZHE units
- 9.4 Extraction Device (Rig, piston, o-rings, filter support): zero headspace extraction vessels manufactured and distributed through Associated Design and

STANDARD OPERATING PROCEDURE

Effective 03/06/2019

SOP Review: 2/12/2021

Page 4 of 12

Manufacturing (Alexandria, VA) or Millipore Corporation (Bedford, MA) meet the design requirements for the procedure.

- 9.5 Glass Syringe (50 ml)
- 9.6 Graduated Cylinders: various sizes (250 mL - 1000 mL)
- 9.7 Drying Oven: capable of maintaining a constant temperature of  $100 \pm 20^{\circ}\text{C}$
- 9.8 Magnetic Stirrer and Stir Bar
- 9.9 pH Meter: accurate to  $\pm 0.05$  units at  $25^{\circ}\text{C}$
- 9.10 Separatory Funnel: 1 or 2 liter
- 9.11 Squeeze Bottles: suitable for methanol and deionized water
- 9.12 Stainless Steel Scoopula
- 9.13 Luer lock adaptor: Adaptor is attached to ZHE outlet valve and screwed directly onto a Tedlar bag to enable minimal exposure to atmosphere during transfer of extraction fluid.
- 9.14 Stainless steel Gas-Tight syringe, 600mL, Associated Design and Manufacturing Company.
- 9.15 Tumbler: Agitation devices manufactured and distributed by Associated Design and Manufacturing (Alexandria, VA) meet minimum requirements for the procedure.
- 9.16 Watch Glass
- 9.17 Stopwatch, preferably digital for tumbler rotation checks.

## 10) Preventative Maintenance

- 10.1 Maintenance is typically limited to routine cleaning and inspection of the ZHE apparatus and equipment. Extraction devices should be thoroughly cleaned and rinsed as described below. All O-rings having gouges or scratches significant enough to compromise the seal of the ZHE apparatus must be discarded.
- 10.2 Cleaning ZHE Units.
  - 10.2.1 ZHE units should be emptied of extracted contents in a fume hood. Open pressure release valve. Open top flange and remove filter supports. Decant unfiltered liquid into the sink or waste bucket. Tap extracted solids into a separate waste bucket or tray. Non-aqueous liquid wastes should be emptied on an absorbent pad. Aqueous wastes and remaining extraction fluid may be rinsed down the sink with the water running. Allow all extracted wastes to vent in the fume hood for several hours prior to disposal or bag all extract waste and remove from the lab to a ventilated waste disposal area.
  - 10.2.2 Rinse ZHE unit with tap water and remove piston. Some units are equipped with a low backpressure release valve that allows the pistons to be forced out of the rig by applying pressure through the pressurization valve. Other units require that the pistons be knocked out with a mallet. If you are unsure as to which unit is equipped with

STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

ZHE

EXT-ZHE, Rev. 1.0

Effective 03/06/2019

SOP Review: 2/12/2021

Page 5 of 12

the low backpressure release valve, do not use pressurized gas to remove pistons.

- 10.2.3 Inspect the piston o-rings for embedded soil, sand, or waste material. Remove o-rings to facilitate cleaning if necessary.
- 10.2.4 Wash all internal surfaces with hot, soapy water. Rinse three times with warm tap water. Rinse three times with deionized water. Air dry.
- 10.2.5 Some wastes will leave a film or residue on the surface of the ZHE unit. These must be cleaned with an appropriate organic solvent. If methanol does not remove the residue, a more compatible solvent such as acetone or methylene chloride can be used. However, if a solvent other than methanol is used, the ZHE unit must be baked at  $100 \pm 20^{\circ}\text{C}$  for four hours prior to use.
- 10.3 The ZHE unit should be checked for leaks after every extraction. After collection of the extract, pressurize to 50psi. Leak-check by either checking the pressure gauge on the unit for loss of pressure (after allowing it to stand for 1 hour), or submerge it in water and check for air bubbles escaping from any of the fittings. If pressure is lost, check all fittings and inspect and replace O-rings, if necessary. Retest the device. If leakage problems cannot be solved, take the unit out of service. Any maintenance tasks performed on leaking vessels must be recorded in the appropriate log book.
- 10.4 Tumbler rotation should be routinely checked to verify proper rotation speed. Measure and record on the bench sheet the tumbler rotation (RPM) when the tumbling is in process.

## 11) Procedure

NOTE: All procedures involving exposure of the waste to the air should be conducted in a hood and in a manner as to reduce loss of volatile compounds.

- 11.1 Preliminary Evaluations: Given the wide range of sample types encountered, some degree of analyst's judgment is necessary when determining if a sample is capable of releasing liquid or not. But in cases when the analyst encounters complex sample types their supervisor or a senior analyst should be consulted for advice. The preliminary evaluation includes, the determination of the percent solids, separation of biphasic liquids, and particle size reduction.
  - 11.1.1 Determine the % filterable solids and % dry solids.
    - 11.1.1.1 If the sample contains moisture that which may produce liquids when subjected to pressure filtration, the following steps are taken. If not, proceed to the particle size reduction section (11.1.6).
    - 11.1.1.2 Pre-weigh the filter on a watch glass and the container that will receive the filtrate. Record the masses.
    - 11.1.1.3 Assemble the ZHE unit and filter as per the manufacturer's instructions.
    - 11.1.1.4 Weigh out 100 grams of the sample and record the mass.

STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

ZHE

EXT-ZHE, Rev. 1.0

Effective 03/06/2019

SOP Review: 2/12/2021

Page 6 of 12

- 11.1.1.5 Allow slurries to settle prior to filtration, centrifuge to aid in filtration if necessary.
- 11.1.1.6 Quantitatively transfer the waste to the ZHE unit (both the liquid and the solid). After that has been completed, make sure that the outlet valve is closed. Apply gentle pressure (<10 psi) to the ZHE unit, then open the valve to begin collecting the filtrate, if no solution has passed through the filter for two minutes, increase the pressure in increments of 10 psi until air passes through the filter or 50 psi is reached. Use only one filter. The portion remaining on the filter is considered the solid phase.
- 11.1.1.7 Determine the weight of the liquid phase by weighing the filtrate container and subtracting the initial mass of the container.
- 11.1.1.8 Subtract the mass of the liquid from the mass of sample filtered to get the mass of the solid phase.
- 11.1.1.9 Calculate the percent filterable solids.

$$\%Filterable\_solids = \frac{Weight\_of\_solid}{Total\_weight\_of\_waste} \times 100$$

- 11.1.2 If the percent solids is <0.5%, then the filtered sample is considered to be the leachate, and no further analysis is required. The filtrate is stored at 0-6°C until VOC analysis is performed. If the sample is >0.5% solids, go to section 11.1.3. If sample is exactly 0.5% solids, consult Project Manager on how to proceed.

- 11.1.2.1 In standard cases (i.e. liquids which will not pass through the filter are not present) remove the solid phase and the filter from the filtration apparatus; else continue to the particle size reduction section (11.1.6).
- 11.1.2.2 Dry the solid phase with the filter at 100 ± 20°C until two successive weight measurements yield the same value within ±1%. Record the final mass.

Note: If the amount of material remaining on the filter will obviously yield solids >50%, note this on the extraction bench sheet, skip the drying step, and proceed to section 11.1.6 and subsequent extraction with this aliquot of waste.

- 11.1.2.3 Calculate the percent dry solids.

$$\%Dry\_solids = \frac{Wt\_of\_dry\_waste + filter}{Initial\_weight\_of\_waste} \times 100$$

- 11.1.3 The following steps (11.1.3.1-11.1.3.3) are for determination of % dry solids only. The % dry solids determination will only be needed on samples that are not obviously >0.5% dry solids. These samples will appear as liquids with some solid matter in the container. The % dry solids determination as performed by other departments (Metals

STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

ZHE

EXT-ZHE, Rev. 1.0

Effective 03/06/2019

SOP Review: 2/12/2021

Page 7 of 12

usually) may be used. In this case % dry solids would not have to be performed by the Extractions department.

11.1.3.1 Carefully remove the filter from the filter assembly and place it on the watch glass that was weighed with the filter in step 11.1.1.2.

11.1.3.2 Place the filter with watch glass in a drying oven and dry for 24 hours. A drying period of 24 hours is not needed if successive weights of the filter and watch glass produce % dry solids within 1% RPD. The filter and watch glass must be in the drying oven for two hours before the first weighing and an interval of one hour must pass between each weighing.

11.1.3.3 Calculate the percent dry solids.

$$\%Dry\_solids = \frac{Final\_filter\_wt - Initial\_filter\_wt}{Total\_wt\_of\_sample} \times 100$$

11.1.4 If percent dry solids are greater than 0.5%, the calculated percent dry solids are used in determining sample amounts for ZHE preparation. If percent dry solids are less than 0.5%, no further analysis is required. The filtrate is defined as the leachate. Store at  $4 \pm 2^{\circ}C$  until VOC analysis is performed in either a VOA vial under zero headspace or in a Tedlar bag. Prepare one filter blank at a rate of one per batch or every 20 (or fewer) samples processed.

11.1.5 Separation of biphasic liquids.

11.1.5.1 Consult the Project Chemist to determine if the client wants both phases analyzed, or if only one of the phases is of interest.

11.1.5.2 Determine phase compatibility. Using a pipette, transfer a few drops of each phase to a small beaker of water. Water miscible phases are identified as “aqueous”. Non-water miscible phases are identified as “non-aqueous”.

11.1.5.3 If both phases are to be analyzed, measure the volume of each phase of the sample into a graduated cylinder (this procedure should be done while the sample is cold). Record these values on the bench sheet. Separate the phases and collect in separate glass containers with minimal headspace. Depending on the client’s needs, results may be reported separately, or as a volume weighted average concentration. Continue with percent solids determination (Section 11.1.1).

11.1.6 Particle Size Reduction (this procedure should be done while the sample is cold)

11.1.6.1 Particle size reduction is required if the solid portion of the waste is larger than 1 cm at its most narrow dimension or has a surface area smaller than  $3.1\text{ cm}^2$ . Surface area criteria are meant for filamentous (e.g. paper, cloth, and similar) waste

materials. Actual measurement of surface area is not required nor recommended.

- 11.1.6.2 Prepare solid wastes by crushing, cutting or grinding. Equipment should be cooled to 4°C if possible. The procedures used to reduce particle size should not generate heat as a result of friction or pressure. Perform the procedure quickly and immediately proceed to the extraction procedure following particle size reduction.

## 11.2 ZHE Leaching Procedure

- 11.2.1 If the liquid phase is non-aqueous as determined in section 11.1.5.2, it must be collected separate from the aqueous leachate. If the liquid phase is aqueous, it will be combined with the leachate following the extraction.

- 11.2.2 If the sample contains between 0.5% and 5% filterable solids, weigh 500 grams for extraction. If the sample contains  $\geq 5\%$  filterable solids the sample mass used for extraction is calculated as follows:

$$\frac{25}{\%Solids} \times 100$$

- 11.2.3 Assemble the ZHE unit. Transfer the entire sample into the ZHE unit. If the remaining residue is greater than 1% of the total sample weight, subtract this amount from the sample amount. Record the sample amount to the nearest 0.1 gram.

- 11.2.4 If during the Preliminary Evaluation (section 11.1) it is determined that the sample is capable of releasing liquid, assemble the top flange and pressurize the unit to 10 psi (make sure the outlet valve on tip of flange is closed before pressurizing unit. Attach the Tedlar bag. Slowly open the outlet valve and begin collecting filtrate. Continue to filter the liquid in 10 psi increments until a maximum pressure of 50 psi is maintained for a period of 2 minutes with no liquid being filtered from the unit. Sample filtrate that is non-aqueous liquid may be stored in either a Tedlar bag (pre-weighed) or VOA vial (pre-weighed) under zero headspace. Regardless of the storage container the weight of the non-aqueous liquid must be recorded for use in the sample volume-weighted average calculation if analysis of separate phases is required. Sample filtrate that is aqueous liquid will be combined with extract in a later step. Store the filtrate at  $4 \pm 2^\circ\text{C}$ .

- 11.2.5 Measure the pH of the extraction fluid on the day of use and record on the ZHE benchsheet prior to proceeding with the volume determination performed in the next step.

- 11.2.6 Determine the appropriate volume (in mL) of extraction fluid to add to the ZHE unit.

$$\frac{20 \times \text{Percent Solids} \times \text{Wt. of waste filtered}}{100}$$

ALS | Environmental – Kelso

ZHE

EXT-ZHE, Rev. 1.0

Effective 03/06/2019

SOP Review: 2/12/2021

Page 9 of 12

- 11.2.7 With the ZHE in the vertical position, attach a line from the extraction fluid reservoir to the liquid inlet/outlet valve. The line used shall contain fresh extraction fluid and should be pre-flushed with fluid to eliminate any air pockets in the line. Release gas pressure on the ZHE piston (from the gas inlet/outlet valve), open the liquid inlet/outlet valve, and begin transferring extraction fluid (by pumping or similar means) into the ZHE. Continue pumping extraction fluid into the ZHE until the appropriate amount of fluid has been introduced into the device. If the calculated amount of extraction fluid will not fit into the extraction unit, add the maximum amount possible and document the amount added.
- 11.2.8 After the extraction fluid has been added, immediately close the liquid inlet/outlet valve and disconnect the extraction fluid line. Check the ZHE to ensure that all valves are in their closed positions. Manually rotate the device end-over-end 2 or 3 times. Reposition the ZHE in the vertical position with the liquid inlet/outlet valve on top. Pressurize the ZHE to 5-10 psi (if necessary) and slowly open the liquid inlet/outlet valve to bleed out any headspace (into a hood) that may have been introduced due to the addition of extraction fluid. This bleeding shall be done quickly and shall be stopped at the first appearance of liquid from the valve. Re-pressurize the ZHE with 5-10 psi and check all ZHE fittings to ensure that they are closed.
- 11.2.9 Close the pressure release valve. Tighten all flanges and valves and pressurize the unit to approximately 10-20 psi. Manually rotate the unit 2-3 times. Open the outlet valve and slowly bleed off excess air from the unit. Close the outlet valve at the first appearance of liquid. Adjust the pressure to 5-10 psi. Tumble the unit for  $18 \pm 2$  hours. Room temperature should be maintained at  $23 \pm 2^\circ$  C. Record the start time and initial temperature on the bench sheet. Measure and record on the bench sheet the tumbler rotation (RPM). Include the temperature graph from Check Point showing room temperature ( $^\circ$ C) while the tumbling is in process.
- 11.2.10 Prepare one extraction blank at a rate of one per batch or every 20 samples processed (if batch size is greater than 20 samples).
- 11.2.11 Turn agitator off. Record stop time. Quickly open and close the pressure release valve. Escape of gas indicates that pressure has been maintained. If no gas escapes the pressure has not been maintained and the extraction must be repeated. Failure to maintain a temperature of  $23 \pm 2^\circ$  C will also result in re-extraction.
- 11.2.12 If a solid-liquid separation was performed and an aqueous filtrate was collected, collect the entire leachate in the Tedlar Bag containing the initial filtrate. Otherwise, collect at least one (two if volume permits) VOA vials of leachate. The leachate needs to have pH checked and recorded. The pH measurement must take place before preservation. Addition of the matrix spike solution must take place before the leachate or leachate/filtrate is preserved. Transfer the leachate to two VOA vials (volume permitting), one pre-preserved with HCL, using a 50 ml syringe that needs no Luer lock adaptor to attach to the outlet valve assembly. Leachate or leachate/filtrate needs to be preserved before

STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

ZHE

EXT-ZHE, Rev. 1.0

Effective 03/06/2019

SOP Review: 2/12/2021

Page 10 of 12

storing in the refrigerator. Preservation is accomplished by adding the leachate or leachate/filtrate to a VOA vial containing 0.5 mL of 1:1 HCL solution. Non-aqueous filtrate produced in step 11.2.4 must be analyzed separately from leachate. Store leachate at  $4 \pm 2^{\circ}\text{C}$ .

11.2.13 All completed paperwork is reviewed by the supervisor or a trained analyst.

## 12) QA/QC Requirements

### 12.1 Initial Precision and Recovery Validation

12.1.1 The accuracy and precision of the procedure must be validated before analyses of samples begin, or whenever significant changes to the procedures have been made. To do this, four replicates of a spiked blank matrix are prepared and analyzed. Results are compared to method criteria. Refer to the determinative method.

### 12.2 Method Detection Limits and Method Reporting Limits

12.2.1 Method detection limits and method reporting limits are based on the determinative procedure. Results for TCLP-ZHE analyses are not routinely reported to the MDL and therefore a separate MDL study is not required.

### 12.3 Method Blanks

12.3.1 A minimum of one Method Blank must be prepared with each batch or with every 20 (or fewer) samples processed. If a Method Blank contains a positively identified target analyte above the MRL, all samples that contain that analyte will be re-extracted, unless the sample results are greater than 20x the level detected in the Method Blank.

12.3.2 The ZHE units used for method blanks are tracked to ensure that out of all ZHE units in use, each unit is used for a method blank a minimum of one time per 20 uses. This is monitored in the lab by rotating the ZHE units used to prepare Method Blanks. Each ZHE unit is labeled with an identification number (inscribed on the unit's body, piston, top flange and bottom flange). Record which unit is used for blank preparation on the bench sheet, and in the extraction fluid preparation log for each run. When setting up a new batch, choose the next ZHE unit in the blank rotation for the method blank.

12.3.3 Unless the Method Blank contamination can be linked to a highly contaminated sample prepared in the batch (i.e., the contamination is the result of volatile transfer from sample to blank during the batch set-up and not as a result of a contaminated ZHE unit), all units resulting in positive ID of a target analyte that was detected in the blank must be thoroughly cleaned and tested before extracting additional samples. Document the verification analysis in the extract fluid preparation log.

## 13) Data Reduction and Reporting

13.1 No data reduction or evaluation steps specific to the ZHE process are required. However, calculations and entries on bench sheets should be checked for

correctness. Review of bench sheets should be documented as part of the data review process for the determinative analysis.

- 13.2 Any sample handling performed as a result of an unusual matrix should be described in the narrative comments accompanying the final report.
- 13.3 If individual phases (aqueous vs. non-aqueous liquid) are to be analyzed separately, determine the volume of the individual phases (to  $\pm 0.5\%$ ), conduct the appropriate analysis, and combine the results mathematically by a volume-weighted average:

$$\text{Concentration} = \frac{(V1)(C1) + (V2)(C2)}{V1 + V2}$$

Where:

V1=the volume of the first phase (L)

C1=the concentration of the analyte of concern in the first phase (mg/L)

V2=the volume of the second phase (L)

C2=the concentration of the analyte of concern in the 2nd phase (mg/L)

#### 14) Method Performance

- 14.1 Refer to the reference method for additional method performance data available.
- 14.2 Available method performance data is given in the reference method. In addition, this procedure was validated through single laboratory studies of accuracy and precision as specified in Section 12. Method Reporting Limits are established for this method based on regulatory action levels and as specified in the ALS Quality Assurance Manual.

#### 15) Pollution Prevention and Waste Management

- 15.1 The laboratory will comply with all Federal, State and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.

#### 16) Contingencies for Handling Our-of-Control or Unacceptable Data

- 16.1 Refer to the SOP for *Non Conformance and Corrective Action*, for procedures for corrective action.
- 16.2 Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

#### 17) Training

- 17.1 All analysts performing this analysis are required to read and understand this SOP.
  - 17.1.1 Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

-----  
Laboratory Director, Charles Byrne

Date: 7-14-2020

	STANDARD OPERATING PROCEDURE	Total Solids (Aqueous)
	ALS   Environmental - Kelso	GEN-160.3 Revision 16.0
		Effective: 7/20/2020
		Page 2 of 8

## 1) Scope & Applicability

- 1.1 This procedure is used to determine total solids using Standard Methods 2540 B-2011 and EPA Method 160.3 and is applicable to drinking, surface, and saline waters, domestic and industrial wastes.
- 1.2 The practical range of the determination is from 5 mg/L to 20,000 mg/L in water. The Method Detection Limit (MDL) is 5 mg/L using 40mL of sample.
- 1.3 For other sample matrices treated on a weight/weight basis, the working range can be as low as 2-100% dry solids. However, samples with less than 5-10% solids are generally treated as water samples.
- 1.4 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DoD ELAP. QC requirements defined in the SOP *Department of Defense Projects - Laboratory Practices and Project Management*, may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 EPA 160.3, 2540 B -2011: A well-mixed sample is quantitatively transferred to a pre-weighed, evaporating dish/crucible and evaporated to dryness at 103 - 105°C. The vessel is weighed and the weight of the residue calculated. Results are reported in mg/L for water.

## 3) Definitions

- 3.1 Total solids - the residue left in the pan or vessel after evaporation of a sample and its subsequent drying in an oven at a defined temperature.
- 3.2 Total volatile solids, also known as volatile residue, is defined as the residue obtained from the determination of total, filterable or non-filterable residue ignited at 550°C in a muffle furnace.
- 3.3 Dry solids are defined as the amount of solid remaining after evaporating off all liquid contained within the sample.
- 3.4 For additional Sample Batch and sample matrix definitions, refer to the SOP for *Sample Batches*, ADM-BATCH.

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory.

## 5) Interferences

- 5.1 For water samples, non-representative particulates such as leaves, sticks, fish and lumps of fecal matter should be excluded from the sample if it is determined that

	STANDARD OPERATING PROCEDURE	Total Solids (Aqueous)
	ALS   Environmental - Kelso	GEN-160.3 Revision 16.0
		Effective: 7/20/2020
		Page 3 of 8

their inclusion is not desired in the final result. However, for other matrices, these particles may be included if they are considered representative of the material undergoing other associated analyses.

- 5.2 Samples containing HF will react with the porcelain crucibles causing a significant weight loss and artificially high results. When analyzing samples containing HF, special Teflon™ crucibles should be used and samples should be evaporated in a ventilation hood to dryness.
- 5.3 The temperature at which the residue is dried has an important bearing on sample results, because weight losses due to the volatilization of organic matter and gases from heat-induced chemical decomposition depend on temperature and time of heating.
- 5.4 Each sample requires close attention to desiccation after drying. Minimize opening the desiccator because moist air enters.
- 5.5 To aid in quality assurance, analyze samples in duplicate. Dry samples to a constant weight. This entails multiple drying-cooling-weighing cycles for each determination.

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS Kelso Chemical Hygiene Plan and in SDSs where available.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Sample bottles should be plastic and must be thoroughly cleaned and rinsed prior to use.
- 7.2 A minimum of 100 mL of sample should be collected for water samples.
- 7.3 Store samples at  $\leq 6^{\circ}$  C and analyzed within 7 days from date of sample collection for water samples.

## 8) Standards, Reagents, and Consumable Materials

- 8.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Refer to the SOP Reagent/Standards Login and Tracking for the complete procedure and documentation requirements.
- 8.2 All stocks, working solutions and sample dilutions should be prepared using deionized water (DI) conforming to ASTM Type I or ASTM Type II reagent water. For more information on reagent water generation, refer to the related SOP, Operation and Maintenance of Laboratory Reagent Water Systems.

## 9) Apparatus and Equipment

- 9.1 Glass vials, 60 mL volume.
- 9.2 Desiccators, containing desiccant.
- 9.3 Drying oven(s), for operation at 103-105°C and at 180 °C

	STANDARD OPERATING PROCEDURE	Total Solids (Aqueous)
	ALS   Environmental - Kelso	GEN-160.3 Revision 16.0
		Effective: 7/20/2020
		Page 4 of 8

9.3.1 Ovens housing an internal temperature recorder/display as part of its operational system are calibrated twice per year by an external, accredited calibration service.

9.3.2 Oven temperature may be monitored by using a thermometer immersed in sand, or other suitable solid material, in a vessel in the oven. The liquid in glass thermometer is verified annually using a reference traceable to NIST.

9.4 Analytical balance capable of weighing to 0.01 mg.

9.5 Glass cylinders.

## 10) Preventative Maintenance

10.1 All maintenance activities are recorded in a maintenance logbook kept for each instrument. Pertinent information (serial numbers, instrument I.D., etc.) must be in the logbook. This includes the routine maintenance described herein. The entry in the log must include: date of event, the initials of who performed the work, and a reference to analytical control.

10.2 Multi-point balance calibration verifications are required for each day the balance is used. The NELAC Quality System Standards and DoD Quality System Manual require that the balance verifications be performed *prior to use* on each day of use. The calibration verification weights must bracket the range of use. For additional information, refer to the SOP *Documenting Laboratory Balance and Temperature Checks* (ADM-BAL).

10.3 A bound logbook or an electronic record is used to record all balance measurements in real time. Format the analytical record such that the date, initials, balance I.D., weight set ID, measurements, and specifications for the check weights are listed for each balance. Entries into logbooks are to be performed in accordance with the SOP for *Making Entries Onto Analytical Records*.

## 11) Procedure

11.1 Heat the clean glass vials (60 mL) to 103-105°C for a minimum of one hour. Cool, and desiccate. Weigh and store in desiccator until ready for use.

11.2 Total Solids Determination

11.2.1 Transfer a measured aliquot of the well mixed sample into the pre-weighed glass vials (100 mL). Wide-bore pipette tips must be used.

11.2.2 Choose an aliquot of sample sufficient to contain a residue of at least 25 mg. To obtain a measurable residue, successive aliquots of sample may be added to the same dish.

11.2.3 Weigh and evaporate to dryness in a drying oven.

11.2.4 If evaporation is performed in a drying oven, the temperature should be lowered to approximately 98°C to prevent boiling and splattering of the sample.

11.2.5 Dry the evaporated sample for at least 1 hour at 103-105°C.

	STANDARD OPERATING PROCEDURE	Total Solids (Aqueous)
	ALS   Environmental - Kelso	GEN-160.3 Revision 16.0
		Effective: 7/20/2020
		Page 5 of 8

- 11.2.6 Transfer samples to a desiccator for final cooling in a dry atmosphere to balance temperature.
- 11.2.7 Weigh samples and record on bench sheet. Return the samples to the 103-105 ° C oven for 1 hour.
- 11.2.8 Repeat the cycle of drying at 103-105°C, cooling, desiccating and weighing until a constant weight is obtained or until loss of weight is less than 4% of the previous weight, or 0.5mg, whichever is less. If not, repeat the cycle of drying, cooling, desiccating and weighing to achieve a constant weight within the referenced acceptance criteria.

## 12) QA/QC Requirements

- 12.1 Prior to, and after each analysis batch, a balance calibration verification (CCV) is performed using at least 2 weights that bracket the sample weight use range. The serial number(s) of the weights used for the CCV determination must be recorded with the analytical record.
- 12.2 Prior to, and after each analysis batch, balance calibration verification is performed using weights bracketing the sample weights (sample + pan). Balance calibration verification measured weights must be  $\pm 0.5\%$  of the true value.
- 12.3 Ongoing QC Samples required are described in the ALS-Kelso Quality Assurance Manual and in the SOP for *Sample Batches* (ADM-BATCH). Additional QC Samples may be required in project specific quality assurance plans (QAPP). For example projects managed under the DOD ELAP must follow requirements defined in the *DoD Quality Systems Manual for Environmental Laboratories*. General QA requirements for DoD QSM are defined in the laboratory SOP, *Department of Defense Projects - Laboratory Practices and Project Management*. General QC requirements are:
- 12.4 Method Blank
  - 12.4.1 A method blank is extracted and analyzed with every batch of 20 (or fewer) samples or one per desiccator, to demonstrate that there are no method interferences. If the method blank shows any hits above the reporting limit, corrective action must be taken. Corrective action includes recalculation, reanalysis, system cleaning, or re-extraction and reanalysis. For some project specific needs, exceptions may be noted and method blank results above the MRL may be reported for common lab contaminants.
- 12.5 Laboratory Control Sample
  - 12.5.1 Run a laboratory control sample (LCS) per batch of 20 (or fewer) samples. For the LCS, a certified quality control standard is purchased from APG as a solid material. Add the standard to DI water in a 1L volumetric flask and dilute to volume (for APG, add all of the material provided). The LCS will be approximately 1000 mg/L, with exact values specified by lot number. Analyze as described above.

Calculate the LCS recovery as follows:

$$\%R = X/TV \times 100$$

Where X = Concentration of the analyte recovered  
TV = True value of amount spiked

12.5.2 The acceptance criteria are given in the ALS Kelso DQO Table. If the LCS fails acceptance criteria, corrective action must be taken. Corrective action includes recalculation, reanalysis.

## 12.6 Sample Duplicate

12.6.1 Run one duplicate per batch of ten samples. The RPD should be  $\leq 5\%$ . This statistically derived acceptance limit is subject to change as limits are updated. For Puget Sound Estuary Program protocols, perform a triplicate analysis per batch of 10 samples. The RSD should be  $\leq 20\%$ .

Calculate Relative Percent Difference (RPD) as:

$$\%RPD = \frac{|R1 - R2|}{(R1 + R2)/2} \times 100$$

Where R1= Higher Result  
R2= Lower Result

## 13) Reporting

### 13.1 Calculations

13.1.1 For water samples, calculate total residue as follows:

$$\text{Total residue, mg / L} = \frac{(A - B) \times 1,000}{C}$$

Where:

A = weight of sample + dish in mg  
B = weight of dish in mg  
C = volume of sample in mL

### 13.2 Reporting

13.2.1 Refer to ADM-RG, Data Reporting and Report Generation for reporting guidelines.

13.2.2 Reports are generated in the ALS LIMS by compiling the SMO login, sample prep database, instrument date, and client-specified report requirements (when specified). The forms generated may be ALS

	STANDARD OPERATING PROCEDURE	Total Solids (Aqueous)
	ALS   Environmental - Kelso	GEN-160.3 Revision 16.0
		Effective: 7/20/2020
		Page 7 of 8

standard reports, DOD, or client-specific reports. The compiled data from LIMS is also used to create EDDs.

13.2.3 Record all measurements.

13.2.4 Report water results in mg/L total solids using whole numbers. The Method Reporting Limit is 5mg/L.

### 13.3 Data Review and Assessment

13.3.1 Following primary data interpretation and calculations, all data is reviewed by a secondary analyst. Following generation of the report, the report is also reviewed. Refer to the *SOP for Laboratory Data Review Process (ADM-DREV)* for details. The person responsible for final review of the data report and/or data package should assess the overall validity and quality of the results and provide any appropriate comments and information to the Project Manager to inclusion in the report narrative.

## 14) Method Performance

14.1 Refer to the reference method for additional method performance data available.

## 15) Pollution Prevention and Waste Management

15.1 The laboratory will comply with all Federal, State and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.

## 16) Contingencies for Handling Out-of-Control or Unacceptable Data

16.1 Refer to the *SOP for Nonconformity and Corrective Action (ADM-NCAR)* for corrective action procedures and to document the proper actions for out of control events.

## 17) Training

17.1 All analysts performing this analysis are required to read and understand this SOP.

17.2 Training is documented following the *Employee Training and New Employee Orientation (ADM-TRAIN)*.

## 18) Method Modifications

18.1 There are no known modifications in this laboratory standard operating procedure from the reference method.

## 19) References

## ALS-Kelso SOP Annual Review Statement

SOP Code: GEN-1020

Revision: 10.0

Attach additional pages or information if necessary

	STANDARD OPERATING PROCEDURE	FLASHPOINT
		GEN-1020, Rev. 10.0
	ALS   Environmental – Kelso	Effective: 2/10/2019
		Page 2 of 15

## 1) Scope & Applicability

- 1.1 This Standard Operating Procedure (SOP) describes the procedure used to determine flashpoint by EPA Method 1020A. The procedure uses the Seta Flash Closed Cup Tester to determine the flashpoint of soil, liquid, and water matrices.
- 1.2 This procedure is applicable to materials with flashpoints between 20°C and 110°C.
- 1.3 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP specific requirements to the laboratory. In general, project specific QAPPs supersede method specified requirements. An example of this are projects falling under DoD ELAP. QC requirements defined in the SOP *Department of Defense Projects – Laboratory Practices and Project Management* (ADM-DOD5) may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 A sample portion is placed in a Setaflash® closed cup tester or its equivalent, and heated, using a flame applied to it at regular intervals, until a flash is observed or the sample heats to greater than 110°C.

## 3) Definitions

- 3.1 Batch - A batch of samples is a group of environmental samples that are prepared and/or analyzed together as a unit with the same process and personnel using the same lot(s) of reagents. It is the basic unit for analytical quality control.
  - 3.1.1 Preparation Batch - A preparation batch is composed of one to twenty field samples, all of the same matrix, and with a maximum time between the start of processing of the first and last samples in the batch to be 24 hours.
  - 3.1.2 Analysis Batch - Samples are analyzed in a set referred to as an analysis sequence. The sequence begins with instrument calibration (initial or continuing verification) followed by sample extracts interspersed with calibration standards (CCBs, CCVs, etc.) The sequence ends when the set of samples has been injected or when qualitative and/or quantitative QC criteria indicate an out-of-control situation.
- 3.2 Sample
  - 3.2.1 Field Sample - An environmental sample collected and delivered to the laboratory for analysis; a.k.a., client's sample.
  - 3.2.2 Laboratory Sample - A representative portion, aliquot, or subsample of a field sample upon which laboratory analyses are made and results generated.
- 3.3 Quality System Matrix - The *matrix* of an environmental sample is distinguished by its physical and/or chemical state and by the program for which the results are

	STANDARD OPERATING PROCEDURE	FLASHPOINT
	ALS   Environmental – Kelso	GEN-1020, Rev. 10.0
		Effective: 2/10/2019
		Page 3 of 15

intended. The following sections describe the matrix distinctions. These matrices shall be used for purpose of batch and quality control requirements.

- 3.3.1 Aqueous - Any groundwater sample, surface water sample, effluent sample, and TCLP or other extract. Specifically excluded are samples of the drinking water matrix and the saline/estuarine water matrix.
- 3.3.2 Non-aqueous Liquid - Any organic liquid with <15% settleable solids.
- 3.3.3 Solids - Any solid sample such as soil, sediment, sludge, and other materials with >15% settleable solids.
- 3.3.4 Chemical waste - Any sample of a product or by-product of an industrial process that results in a matrix not described in one of the matrices. These can be such matrices as non-aqueous liquids, solvents, oil, etc.
- 3.3.5 Miscellaneous matrices - Samples of any composition not listed. These can be such matrices as plant material, paper/paperboard, wood, auto fluff, mechanical parts, filters, wipes, etc. Such samples shall be batched/grouped according to their specific matrix.
- 3.4 Laboratory Duplicates (DUP) - Duplicates are additional replicates of samples that are subjected to the same preparation and analytical scheme as the original sample. The relative percent difference (RPD) between the sample and its duplicate is calculated and used to assess analytical precision.
- 3.5 Method Blank (MB) - The method blank is an artificial sample composed of analyte-free water or solid matrix and is designed to monitor the introduction of artifacts into the analytical process. The method blank is carried through the entire analytical procedure.
- 3.6 Laboratory Control Samples (LCS) - The LCS is an aliquot of analyte free water or analyte free solid to which known amounts target analytes are added. The LCS is prepared and analyzed in exactly the same manner as the samples. The percent recovery is compared to established limits and assists in determining whether the batch is in control.

#### 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. Final review and sign-off of the data is performed by the department supervisor/manager or designee.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training. Documenting method proficiency, as described in the ALS-Kelso *SOP for*

	STANDARD OPERATING PROCEDURE	FLASHPOINT
	ALS   Environmental – Kelso	GEN-1020, Rev. 10.0
		Effective: 2/10/2019
		Page 4 of 15

*Training Procedure* (ADM-TRAIN), is also the responsibility of the department supervisor/manager.

## 5) Interferences

- 5.1 Water will create a false flash at approx. 55° - 68°C. The analyst must be sure to recognize the difference between water BLOWING a flame out, and volatiles SUCKING a flame in.
- 5.2 Interferences and artifacts can be introduced into the procedure from field samples. Ensure that these interferences are minimized by cleaning the apparatus after each determination.

## 6) Safety

- 6.1 All appropriate safety precautions for handling solvents, reagents and samples must be taken when performing this procedure. This includes the use of personal protective equipment, such as, safety glasses, lab coat and the correct gloves.
- 6.2 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Sample Collection
  - 7.1.1 Samples may be collected in any labeled glass container suitable for environmental samples. Care should be taken not to spill the sample onto the exterior of the container.
- 7.2 Sample Preservation and storage
  - 7.2.1 Water and soil samples should be iced or refrigerated at  $4 \pm 2^{\circ}\text{C}$  from time of collection until analysis. Miscellaneous waste samples may be stored refrigerated or at room temperature. If the waste may result in cross-contamination of other refrigerated samples, storage outside the refrigerated areas is advised.

## 8) Standards, Reagents, and Consumable Materials

- 8.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Refer to the *SOP Reagent/Standards Login and Tracking (ADM-RTL)* for the complete procedure and documentation requirements.
- 8.2 All stocks, working solutions and sample dilutions should be prepared using deionized water (DI) conforming to ASTM Type I or ASTM Type II reagent water. For more information on reagent water generation, refer to the related SOP, Operation and Maintenance of Laboratory Reagent Water Systems.

	STANDARD OPERATING PROCEDURE	FLASHPOINT
	ALS   Environmental – Kelso	GEN-1020, Rev. 10.0
		Effective: 2/10/2019

8.3 p-Xylene (flashpoint of 25.5°C)

8.4 1-Butanol

8.5 Ice.

## 9) Apparatus and Equipment

9.1 Seta Flash Closed Cup Tester, STANHOPE-SETA, SETAFLASH SERIES 3, MODEL 32000-0, SN"7069.

9.2 Scoopulas

9.3 Barometer

9.4 Transfer pipette

## 10) Preventative Maintenance

10.1 All maintenance activities are recorded in a maintenance logbook kept for each instrument. Pertinent information (serial numbers, instrument I.D., etc.) must be in the logbook. This includes the routine maintenance described herein. The entry in the log must include: date of event, the initials of who performed the work, corrective action and a reference to analytical control.

10.2 The unit's internal thermometer shall be verified at a minimum, annually using a NIST traceable reference thermometer. The Calibration Mode is only accessible from power up. The procedure is carried out via the panel controls and requires a NIST Reference Thermometer and some thermos-conductive paste. The Tester is provided with an aperture at the right hand side of the cup/heating block assembly for insertion of the thermometer, allowing accurate verification and calibration of the cup/heating block assembly temperature. Refer to the Calibration section of the Operating and Instruction Manual associated with the unit.

10.3 In the event of a problem, please check the items specified in the Small Scale Diagnostic Checklist, the Manufacturer's Fault Finding Guide and the recommended service and maintenance schedule in Attachment A.

10.4 For additional maintenance and repair, for example, replacing a flash detector probe, the sample well "O" ring seal, gas canister and tubing or the lid shutter assembly, refer to the referenced STANHOPE-SETA MODEL: 32000-00, Installation, Operating and Maintenance Instructions Manual

## 11) Procedure

11.1 Record all measurements on the appropriate benchsheet. The analysis sequence starts with a p-xylene calibration check and a 1-butanol calibration check followed by a method blank and up to 20 field samples, including one sample duplicate every 10 samples.

11.2 General procedure for flashpoint determination

11.2.1 Record the barometer reading.

11.2.2 Turn on the Setaflash® unit. Push and hold the temperature adjust button and turn knob to 20°C.

	STANDARD OPERATING PROCEDURE	FLASHPOINT
		GEN-1020, Rev. 10.0
	ALS   Environmental – Kelso	Effective: 2/10/2019
		Page 6 of 15

- 11.2.3 Add test or calibration material to cup.
- 11.2.4 If the sample does not appear to flash or ignite, proceed to the next step. If the sample appears to ignite, before increasing the temperature, place < 1.0mL of sample in an aluminum weigh dish in the hood. Apply a flame to this sample. If the sample ignites, immediately extinguish the flame and record the temperature as <20°C.
- 11.2.5 Apply the flame to the sample at 20°C intervals until a flash is observed or the unit reaches 110°C.
- 11.2.6 If no flash was observed, retest using the timer at 110°C. If no flash is still observed, record >110°C. Note: p-xylene should flash at 27°C and 1-butanol should flash at 37°C.
- 11.2.7 If a flash was observed, turn off the unit, empty sample out of the cup and cool cup down (with ice) to approximately 10°F below observed flash temperature.
- 11.2.8 Use the timer and apply the flame at to the sample at 1°C intervals until a flash is observed or the unit reaches 110°C.
- 11.2.9 If no flash was observed, record >110°C.
- 11.2.10 If a flash was observed, record the temperature.
- 11.2.11 Turn off the unit; wash the cup with deionized water; place refuse in a sealable, plastic bag.
- 11.3 Calibration check and method blank procedure
  - 11.3.1 For the calibration check, add 2 mL of p-Xylene directly into the cup of the Seta flash unit and close the lid.
  - 11.3.2 Follow the general procedure for flashpoint determination.
  - 11.3.3 Analyze a 2 mL portion of 1-butanol and record the results.
  - 11.3.4 For the method blank, pipette 2 mL of DI Water into the Seta Flash instead of p-xylene.
- 11.4 Sample analysis procedure
  - 11.4.1 Place approximately 2 mL or 2 g of sample into the Seta Flash cup.
  - 11.4.2 Follow the previously described procedure for flashpoint determination.
- 11.5 At end of run sequence, record the Barometer reading.

## 12) QA/QC Requirements

- 12.1 This method shall operate under the formal Quality Assurance Program established at ALS and must maintain records that define the quality of data that is generated. Data shall be compared to established criteria in order to determine

if the results of the analyses meet the performance characteristics of the method. It is required that an initial demonstration of capability and periodic analysis of laboratory reagent blanks, laboratory fortified blanks, and other QC solutions as a continuing check on performance. The accuracy and precision of the procedure must be validated before analyses of samples begin, or whenever significant changes to the procedures have been made.

- 12.2 The Method Reporting Limits (MRLs) used at ALS are the routinely reported lower limits of quantitation which take into account day-to-day fluctuations in instrument sensitivity as well as other factors. These MRLs are the levels to which ALS routinely reports results in order to minimize false positive or false negative results. The MRL is normally two to ten times the method detection limit.
- 12.3 Ongoing QC Samples required are described in the ALS-Kelso Quality Assurance Manual and in the SOP for Sample Batches. Additional QC Samples may be required in project specific quality assurance plans (QAPP). General QA requirements for DoD QSM are defined in the laboratory SOP, Department of Defense Projects - Laboratory Practices and Project Management (ADM-DOD5). General QC Samples are:

#### 12.3.1 Method Blank

12.3.1.1 A method blank is extracted and analyzed with every batch of 20 (or fewer) samples to demonstrate that there are no method interferences. If the method blank shows any hits above the reporting limit, corrective action must be taken. Corrective action includes recalculation, reanalysis, system cleaning, or re-extraction and reanalysis. For some project specific needs, exceptions may be noted and method blank results above the MRL may be reported for common lab contaminants.

- 12.3.2 Sample Duplicates - One sample per batch of 10 or fewer samples must be analyzed in duplicate. Relative Percent Difference must be  $\leq 20\%$ .

Calculate Relative Percent Difference (RPD) as:

$$RPD = \frac{|R1 - R2|}{(R1 + R2)/2} \times 100$$

Where  $R1$  = Result for the sample

$R2$  = Result for the sample duplicate

- 12.4 Due to the nature of the test, the determination of method detection limits, and the analysis of matrix spike or LCS samples is not applicable.

### 13) Data Reduction and Reporting

- 13.1 Calculate the flashpoint as follows:

$$\text{Flashpoint} = A + 0.06(760 - B)$$

Where: A = Observed flashpoint

	STANDARD OPERATING PROCEDURE	FLASHPOINT
	ALS   Environmental – Kelso	GEN-1020, Rev. 10.0
		Effective: 2/10/2019
		Page 8 of 15

B = Average Barometric Pressure (mm Hg).

### 13.2 Data Reporting

13.2.1.1 It is the analyst's responsibility to review analytical data to ensure that all quality control requirements have been met for each analytical run. Results for QC analyses are calculated and recorded as specified in this SOP. QC results are entered on the analytical spreadsheet for corresponding samples. All data will be initialed, dated and attached to required data quality worksheet.

13.2.1.2 Reports are generated in the ALS LIMS by compiling the SMO login, sample prep database, instrument date, and client-specified report requirements (when specified). This compilation is then transferred to a file which [REDACTED] uses to generate a report. The forms generated may be ALS standard reports, DOD, or client-specific reports. The compiled data from LIMS is also used to create EDDs.

### 13.3 Data Review and Assessment

13.3.1 Following primary data interpretation and calculations, all data is reviewed by a secondary analyst. Following generation of the report, the report is also reviewed. Refer to the *SOP for Laboratory Data Review Process* (ADM-DREV) for details. The person responsible for final review of the data report and/or data package should assess the overall validity and quality of the results and provide any appropriate comments and information to the Project Manager to inclusion in the report narrative.

## 14) Contingencies for Handling Out-of-Control or Unacceptable Data

14.1 Refer to the SOP for *Non Conformance and Corrective Action* for procedures for corrective action. Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

### 14.2 Handling out-of-control or unacceptable data

14.2.1 On-the-spot corrective actions that are routinely made by analysts and result in acceptable analyses should be documented as normal operating procedures, and no specific documentation need be made other than notations in laboratory maintenance logbooks, run logs, for example.

14.2.2 Some examples when documentation of a nonconformity is required using a Nonconformity and Corrective Action Report (NCAR):

- Quality control results outside acceptance limits for accuracy and precision.
- Method blanks or continuing calibration blanks (CCBs) with target analytes above acceptable levels.
- Sample holding time missed due to laboratory error or operations.

	STANDARD OPERATING PROCEDURE	FLASHPOINT
	ALS   Environmental – Kelso	GEN-1020, Rev. 10.0
		Effective: 2/10/2019
		Page 9 of 15

- Deviations from SOPs or project requirements.
- Laboratory analysis errors impacting sample or QC results.
- Miscellaneous laboratory errors (spilled sample, incorrect spiking, etc.).
- Sample preservation or handling discrepancies due to laboratory or operations error.
- Customer inquiries concerning data quality or services (when applicable). NCAR not required for simple corrections with no impact to the client.
- Data errors reported to clients, non-conforming re-checks.
- Deficiencies found during internal or external audits.
- Login errors or shipping errors.
- IT issues if there is a significant impact to a client.
- Turnaround time complaints.

## 15) Method Performance

15.1 Refer to the reference method for additional method performance data available.

## 16) Pollution Prevention and Waste Management

16.1 It is the laboratory's practice to minimize the amount of solvents, acids and reagent used to perform this method wherever feasible. Standards are prepared in volumes consistent with methodology and only the amount needed for routine laboratory use is kept on site. The threat to the environment from solvent and reagents used in this method can be minimized when recycled or disposed of properly.

16.2 The laboratory will comply with all Federal, State and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.

16.3 This method uses non-halogenated solvents. Waste solvents generated through the lab ware cleaning, sample prep, and LC mobile phase usage are collected in containers near the point of creation. They are then stored at a satellite storage center in the OLC lab which is transferred weekly to the main facility waste management area. The waste solvent will then be added to the hazardous waste storage area and disposed of in accordance with Federal and State regulations

## 17) Training

17.1 Training outline

17.1.1 Review literature (see References section). Review the SOP. Also review safety procedures. Following these reviews, observe the procedure performed by an experienced analyst at least three times. .

17.1.2 The next training step is to assist in the procedure under the guidance of an experienced analyst. During this period, the analyst is expected to transition from a role of assisting, to performing the procedure with minimal oversight from an experienced analyst.

17.1.3 Perform initial precision and recovery (IPR) study as described above for

water samples. Summaries of the IPR are reviewed and signed by the supervisor. Copies may be forwarded to the employee's training file. For applicable tests, IPR studies should be performed in order to be equivalent to TNI's Initial Demonstration of Capability.

- 17.2 Training is documented following the *ALS-Kelso Training Procedure (ADM-TRAIN)*.
- 17.3 When the analyst training is documented by the supervisor on internal training documentation forms, the supervisor is acknowledging that the analyst has read and understands this SOP and that adequate training has been given to the analyst to competently perform the analysis independently.

## 18) Method Modifications

- 18.1 Not applicable.

## 19) References

- 19.1 DoD Quality Systems Manual for Environmental Laboratories Current Version.
- 19.2 TNI Standard, Volume 1- 2009, TNI Standard, Volume 1- 2016.

## 20) Changes since Last Revision

Summary of Revision Changes			
Revision Number	Effective Date	Document Editor	Description of Changes
10.0	2/10/2019	T.Caron	Reformatted SOP to current ALS branding;

## 21) Attachments, Tables, and Appendices

- 21.1 Attachment A: Small scale diagnostic checklist.
- 21.2 Attachment B: Table of Corrective Actions.
- 21.3 Attachment C: Internal Thermometer Calibration Procedure.

ATTACHMENT A

Small Scale Diagnostic Checklist

In the event of a problem, please check the following items: General

Is the instrument level and situated in a draft free area?	
Have you obtained good results when verifying with a Certified Reference Material (CRM)? (Certified Reference Material 99878-3)	
Has the correct size sample been used when testing?	
Has the sample been tested at the correct temperature?	
If applicable, when running an equilibrium test, was the correct test duration used? (Please be advised this will vary depending on the sample size)	
Has the instrument been maintained in accordance with the routine maintenance schedule? (Checks: O-ring and tubing for damage. Clean: Cup, Lid and Shutter)	
Is the Flash Detector damaged? (Visually inspect to ensure the tip is not bent and that the two wires are connected to the small soldered ball)	
Is the correct O-ring fitted?	
Is the O-ring sealing on the lid?	
If applicable, is the ignitor wire undamaged and dipping to the correct depth?	
If applicable, is the flame size correct and dipping to the correct depth?	
Is the unit correcting the flash point correctly in comparison to the barometric pressure?	
Is the syringe being removed from the lid and shutter once the sample has been injected?	

ATTACHMENT A (Cont.)

Service & Maintenance Schedule			
	After Test	6 Monthly	Annually
Wipe clean the Sample Cup	●	●	
Wipe clean the O-ring	●	●	
Wipe clean the Lid and Shutter	●	●	
Visually inspect the Sample Cup O-ring	●	●	
Wipe the exterior of the Bath clean of spillages, splashes and residues		●	
Calibrate the pressure		●	
Clean the injection port			
Clean / replace the syringe			
Calibrate the temperature			●
Service and calibration			●

FAULT	POSSIBLE CAUSE	USER REMEDY (section)
Erroneous temperature display or other	Random program error	Try switching off unit for 5 seconds and switching back on again
No illumination on panel display when power is switched on	No power to the Tester	Check that the power supply is available and switched on (2.3)
	Fuse failed	Check fuse on rear panel (2.3)
	Wrong voltage setting	Check voltage setting (both voltage selectors) (2.3)
LED on panel remains off when cup temperature exceeds 55°C	LED failed	Return to factory for repair
	Circuit board failed	Return to factory for repair
LED on panel constantly lit but cup/heating block assembly fails to	Faulty circuit board	Return to factory for repair
Difficult to light gas supply	Gas flow rate erratic	Adjust control valve on gas canister (3.2.2)
	Gas leaking from tube	Inspect silicone rubber tubing and replace if necessary (9.3)
	Gas canister low or empty (flame very small)	Refill gas canister (2.6)
Flash point value too low	Sample contaminated	Check sample for contamination and clean sample cup, filler orifice, Hd and shutter where appropriate
	Test flame incorrect size	Check that test jet is set correctly (compare with flame size mark engraved on top of
Flash point value too high	Poor sample preparation Vapor leakage	Prepare fresh sample
		Inspect lid and shutter for slide wear (9.4)
	Test flame incorrect size	Check condition of O-ring seal and replace if necessary (9.2)  Check that test jet is set correctly (compare with flame size mark engraved on top of
Gas supply fails to turn off	On/off gas valve obstructed	Replace gas canister assembly (9.3)
	On/off gas valve broken	Replace gas canister assembly (9.3)
Flash detector probe does not detect a flash or display shows message 'O/C'	Probe not plugged into socket at rear Faulty probe Faulty circuit board	Plug in probe (9.1) Replace probe (9.1) Return to factory for repair
Unable to calibrate, temperature unstable	Faulty circuit board	Return to factory for repair
	Faulty heater	Return to factory for repair

## ATTACHMENT C

Pubn:- 32000H0H

### 4. CALIBRATION

The Calibration Mode is only accessible from power up. The Setaflash Series 3 Flash Point Testers are calibrated for temperature using a single point method. The procedure is carried out via the panel controls and only requires a reference thermometer and some thermo-conductive paste. The Tester is provided with an aperture at the right hand side of the cup/heating block assembly for insertion of the thermometer, allowing accurate verification and calibration of the cup/heating block assembly temperature.

- (1) Insert some thermo conductive paste into the aperture on the right hand side of the cup/heating block, and then insert a 0 - 110°C calibrated reference thermometer (Seta 13751-0 recommended) as far into the cup/heating block as it will go.
- (2) Press and hold down the set temperature  and set timer  buttons simultaneously whilst switching on the Tester. The display will momentarily show:-

Version Vx.xx

(x.xx is the software version)  
followed by:-

Calibrate mode  
please wait..

- (3) Release both buttons. The cup/heating block assembly will heat up to 55°C as measured by the Setaflash Flash Point Tester.
- (4) When the Setaflash measures the temperature of the cup/heating block assembly as 55°C the display will change to show:-

Calibrate mode  
please wait 300

and commence to countdown to zero.

- (5) When the countdown reaches zero, the temperature of the cup/heating block assembly has stabilised. An audible warning (beep) will be heard and the display will change to show:-

Thermometer T? >  
55.0°C

- (6) Wait until the calibration thermometer reading is stable. This may take several more minutes.
- (7) Rotate the control knob clockwise or anti clockwise until the temperature as measured by the thermometer is shown in the second line of the display. One "click" of the knob will change the temperature of the cup/heating block assembly by approximately 0.1°C.
- (8) Press the set timer button . The display will change to show:-

SWITCH OFF

- (9) Switch the Setaflash Tester off, using the power switch on the rear of the tester.

*ATTACHMENT C (Cont.)*

- (10) Check that the calibration has been successful by repeating steps (2) to (6). The display and thermometer should show the temperature of the cup/heating block assembly as 55.0°C ( $\pm 0.1^\circ\text{C}$ )
- (a) If the calibration appears correct, switch the Setaflash Tester off using the power switch at the rear of the tester and remove the thermometer.
  - (b) If the calibration is incorrect, carry out steps (2) to (10) to repeat the calibration procedure.

**Note:** If repeated attempts at calibration are unsuccessful, refer to Section 8 - FAULT FINDING.

## Total Carbon in Soil

DOCUMENT ID: GEN-ASTM, REVISION 14.0

Prepared By:   
Inorganics Manager, Jeff Coronado

Date: 10/23/20

Prepared By:   
Quality Assurance Manager, Kurt Clarkson

Date: 10/23/20

Approved By:   
Laboratory Director, Charles (Pat) Byrne

Date: 10/23/2020

	STANDARD OPERATING PROCEDURE	Total Organic Carbon in Soil
	ALS   Environmental - Kelso	GEN-ASTM, Rev. 14.0
		Effective: 10/30/2020
		Page 2 of 13

## 1) Scope & Applicability

- 1.1 This procedure is applicable to the determination of Total Carbon, Total Organic Carbon (TOC), and Total Inorganic Carbon using ASTM Method D4129-05 or EPA Method 9060A modified for soil and sediment matrices (Puget Sound Estuary Program and Lloyd Kahn). Total organic carbon is a measure of the total amount nonvolatile, partially volatile and particulate organic compounds in a sample. The sample should be acidified to remove inorganic carbon (carbonates, bicarbonates, free CO<sub>2</sub> etc.), prior to analysis. Total Carbon (TC) results are determined by analysis of an untreated, non-acidified, sample. Total Inorganic Carbon (TIC) can be determined by difference, subtracting TOC from TC.
- 1.2 This method is applicable to all soils and sediments and most matrices that can be dried and ground to a fine powder.
- 1.3 Results are reported as percent (%) carbon, and the applicable range is the MDL to 100%. The Method Reporting Limit (MRL) for TOC is 0.05% dry weight basis by methods ASTM D4129-05, PSEP, and Lloyd Kahn. The MRL for TOC by EPA 9060A is 0.1%. Equivalent nomenclature for MRL includes Estimated Quantitation Limit (EQL). Therefore, MRL=EQL. The Method Detection Limit (MDL) has been determined at 0.02%
- 1.4 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DoD ELAP. QC requirements defined in the SOP *Department of Defense Projects - Laboratory Practices and Project Management*, may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 Samples are combusted in an oxygen atmosphere to convert organic and inorganic forms of carbon to CO<sub>2</sub>. The combustion temperature is selected to completely oxidize all carbon forms. The combustion product gases are swept through a barium chromate catalyst/scrubber to ensure that all of the carbon is oxidized to CO<sub>2</sub>. Other potentially interfering product gases such as SO<sub>2</sub>, SO<sub>3</sub>, HX, and NO<sub>x</sub> are removed from the gas stream in a series of chemical scrubbers. By ASTM Method D4129-05 the CO<sub>2</sub> is then swept to the coulometer where it is detected by automatic, coulometric titration, with coulometric end point indication. If performing EPA Method 9060A, the CO<sub>2</sub> is determined using an infrared detector.
- 2.2 The coulometer cell is filled with a partially aqueous medium containing ethanolamine and a colorimetric indicator. When a gas stream passes through the solution, CO<sub>2</sub> is quantitatively absorbed. CO<sub>2</sub> reacts with the ethanolamine to form a strong titratable acid which caused the indicator to fade. The titration current automatically turns on and electrically generates base to return the solution to its original color.

## 3) Definitions

- 3.1 For laboratory definitions applicable to most analyses, refer to the SOP for [Sample Batches](#).

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of

	STANDARD OPERATING PROCEDURE	Total Organic Carbon in Soil
	ALS   Environmental - Kelso	GEN-ASTM, Rev. 14.0
		Effective: 10/30/2020
		Page 3 of 13

the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. The department supervisor/manager or designee performs final review and sign-off of the data.

- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency as referenced in *Employee Training and Orientation*, ADM-TRAIN.

## 5) Interferences

- 5.1 Acidic and other gases, including SO<sub>2</sub>, SO<sub>3</sub>, H<sub>2</sub>S, HCl, HBr, HI, Cl<sub>2</sub>, and NO<sub>x</sub> can be effectively removed using scrubbers such as KI, Ag<sub>2</sub>SO<sub>4</sub>, AgNO<sub>3</sub>, and MnO<sub>2</sub>.
- 5.2 Volatile organics may be lost in the decarbonization process.

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.
- 6.2 Hydrochloric and/or Nitric Acid are used in this method. These acids are extremely corrosive and care must be taken while handling them. A face shield should be used while pouring acids. And safety glasses should be worn while working with the solutions. Lab coat and gloves should always be worn while working with these solutions.
- 6.3 Do not attempt to combust large samples of organic or other materials that will react with pure oxygen. Such samples can cause the pyrolysis tube to explode.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Samples should be collected in plastic bottles. There are no requirements for chemical preservation.
- 7.2 Samples should be stored refrigerated at 4 ± 2°C. Samples must be analyzed within 28 days of sampling. If the samples are frozen the holding time is extended to 6 months.

## 8) Apparatus and Equipment

- 8.1 Induction furnace, Coulometrics Incorporated with CO<sub>2</sub> coulometer.
- 8.2 Combustion furnace with IR detector (Analytik Jena Multi EA 4000) with autosampler.
- 8.3 Analytical balance, 0.1 mg accuracy.
- 8.4 Desiccator.
- 8.5 Quartz combustion boats.
- 8.6 Sample scoop.
- 8.7 Porcelain boats. Glass ladles and miscellaneous laboratory glassware.

## 9) Standards, Reagents, and Consumable Materials

- 9.1 Reagents

9.1.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Standards, reagents and consumable material documentation shall indicate traceability to purchased neat materials or compounds. Refer to the SOP *Reagent/Standards Login and Tracking* (ADM-RTL) for the complete procedure and documentation requirements.

9.1.2 Reagents and Standards must comply with the traceability, labeling and documentation practices specified in the SOPs: *Making Entries onto Analytical Records, Quality of Reagents and Standards* and *Reagent and Standards Login and Tracking* (ADM-RLT).

## 9.2 Standards

9.2.1 ASTM D4129, PSEP and Lloyd Kahn:

9.2.1.1 Urea - 20% carbon - use 10 mg for the CCV and 5 mg for the MS/MSD.

9.2.2 EPA 9060A

9.2.2.1 Calcium Carbonate ( $\text{CaCO}_3$ ) - 12% carbon - use 25 mg for the CCV and the MS/MSD.

9.2.3 Nutrients in Soil, purchased standard with a known TOC value (typically ERA #542).

9.2.3.1 ASTM 4129, PSEP, and Lloyd Kahn - use 50 mg for the LCS.

9.2.3.2 EPA 9060A. - Use 250 mg for LCS.

## 9.3 Reagents

9.3.1 Hydrochloric acid, 50% and 10%.

9.3.1.1 10%: Bring 20mL HCl to 200mL final volume.

9.3.1.2 50%: Bring 100mL HCl to 200mL final volume.

9.3.2 Carbon Cathode Solution. Dimethyl Sulfoxide; DMSO. Purchased from Coulometrics Inc. as a prepared solution. Used for coulometer solution.

9.3.3 Anode Solution. Dimethyl Sulfoxide and potassium iodide. Purchased from Coulometrics Inc. as prepared solution.

9.3.4 Manganese dioxide. Gas scrubber solution.

9.3.5 Potassium Hydroxide. Gas scrubber solution.

9.3.6 Potassium Iodide. Anode chemical.

9.3.7 Magnesium Perchlorate desiccant.

9.3.8 Halogen Absorber, silver.

9.3.9 Oxygen, Compressed gas, 4.3 UHP purity or better.

## 10) Preventive Maintenance

10.1 All maintenance activities are recorded in a maintenance logbook kept for each instrument. Pertinent information (serial numbers, instrument I.D., etc.) must be in the logbook. This includes the routine maintenance described herein. The entry in the log

	STANDARD OPERATING PROCEDURE	Total Organic Carbon in Soil
	ALS   Environmental - Kelso	GEN-ASTM, Rev. 14.0
		Effective: 10/30/2020
		Page 5 of 13

must include: date of event, the initials of who performed the work, and a reference to analytical control.

10.2 Maintenance is performed as follows:

<u>Maintenance Item</u>	<u>Frequency</u>
Cell	Clean daily with methanol and water to clean frit
Mg Perchlorate Scrubber	change daily
KOH Scrubber	change monthly
NOX scrubber	change as needed
Repack Pre-combustion Column	as needed
Repack Combustion Column	as needed
Repack Halogen Scrubber	as needed

10.3 Check oven temperature with high temperature thermocouple thermometer on a quarterly (three month) basis. Temperature reading should be within  $\pm 5\%$  of instrument temperature reading. If reading is outside specification, appropriate steps must be taken to bring temperature to within acceptable limits. Any actions taken must be documented in maintenance logbook.

## 11) Procedure

### 11.1 ASTM Method D4129-05, PSEP, and Lloyd Kahn.

#### 11.1.1 Sample Preparation.

11.1.1.1 Turn furnace on to  $\approx 1000^{\circ}\text{C}$ . Allow furnace to warm-up for about 1/2 hours. Turn on oxygen to  $\approx 5$  psi and 75 to 125 ml/min at flowmeter.

11.1.1.2 Clean quartz boats. Scrape out old sample and rinse boats with DI water. Place boats in crucible and muffle for at least 10-15 minutes. Remove boats and place in desiccator until ready for use.

11.1.1.3 Samples should be dried at  $70^{\circ}\text{C}$  and homogenized prior to analysis. Homogenization of dried solid sample should include grinding with a mortar and pestle or shatter box. A shatter box should be used with a larger sample size (i.e. 20+ grams) if the sample exhibits a high degree of heterogeneity. Samples should be ground to a fine, homogenous, powder.

11.1.1.4 Ground samples must be stored in individual sealed vials. In addition, sample vials analyzed under PSEP methodology must be stored in a desiccator prior to sample analysis.

11.1.1.5 As a rule, the darker (or closer to black) a sample is, the more carbon it contains. Place a small portion of sample on a watch glass. Add 1 drop of 10% HCl. Watch for effervescence or bubbling. If bubbles are present, the sample contains inorganic carbon ( $\text{CO}_3$ ). If sample bubbles, reduce sample size to prevent sample from bubbling out of boat. If sample is dark, wood product or sludge reduce sample volume to 5 - 10mg. Normal sample volume = 50mg. After boats are loaded with sample add 1 to 2 drops 10% HCl to each sample, LCS, and method blank. Place boats in  $70^{\circ}\text{C}$  oven to dry. If samples bubbled when acid was added, add 1 to 2 drops more acid and dry at  $70^{\circ}\text{C}$ . Continue acidifying and drying until samples no longer bubble.

#### 11.1.2 Apparatus Preparation.

- 11.1.2.1 Fill cell with carbon cathode solution to 100 - 125 ml, drop in stir bar. Place cell top on snug.
- 11.1.2.2 Cover bottom of anode cell with KI. About 2 small scoops.
- 11.1.2.3 Add carbon anode solution to cell such that when anode is inserted in the anode cell, the anode solution level is the same as the cathode solution level.
- 11.1.2.4 Place cell in coulometer cell holder.
- 11.1.2.5 Turn on detector lamp and stir plate. (Power on).
- 11.1.2.6 Turn adjust knob to 122 (all the way to the right) then turn back down to 100. Rotate cell until maximum transmittance is obtained.
- 11.1.2.7 With oxygen bubbling to cell and maximum transmittance obtained, turn on the current to the anode and cathode. The carbon cathode solution will begin to titrate to a blue color.
- 11.1.2.8 Change Magnesium Perchlorate desiccant daily.
- 11.1.2.9 The instrument is now ready to run.
- 11.1.3 Calibration and Standardization.
- 11.1.3.1 Burn both ladles for five minutes each to remove any residual TOC.
- 11.1.3.2 Establish baseline.
- 11.1.3.3 Burn three empty boats five minutes each. The average of the three runs is the baseline.
- 11.1.4 Analysis.
- 11.1.4.1 Place one platinum or quartz boat in a ladle. Simultaneously insert the sample into the furnace, press the reset button on the coulometer and start the timer for five minutes.
- 11.1.4.2 After five minutes, obtain a reading from the instrument. Remove the ladle from the furnace. (Occasionally, a high sample may require longer than 5 minutes to complete the titration).
- 11.1.4.3 Load the other ladle with the next platinum (or quartz) boat. Remove the ladle in use from the inlet port and insert the next ladle.
- 11.1.4.4 Repeat the analysis steps until all the samples are analyzed.
- 11.2 EPA Method 9060A – IR detection
- 11.2.1 Sample Preparation.
- 11.2.1.1 Samples are homogenized and aliquoted into labeled aluminum pans. The samples are dried in a 70°C oven and then ground into a powder with a mortar and pestle or shatter box. The ground samples should be stored in labeled vials.
- 11.2.1.2 Weigh 250 mg of ground sample into a pre-muffled porcelain boat. Weigh to the nearest 0.1 mg. A smaller portion can be weighed if high carbon content is suspected so that the calibration range is not exceeded.

STANDARD OPERATING PROCEDURE	Total Organic Carbon in Soil
	GEN-ASTM, Rev. 14.0
ALS   Environmental - Kelso	Effective: 10/30/2020
	Page 7 of 13

11.2.1.3 Acidify all samples with 10% HCl and dry in a 70°C oven. Continue to acidify and dry each sample until bubbling stops. Once the samples stop reacting with the HCl, they are ready for analysis.

#### 11.2.2 Instrument Preparation.

11.2.2.1 The instrument needs to be calibrated once a year. The instrument may need to be recalibrated sooner if CCVs or LCSs continue to fail without resolution or if major maintenance has been performed. To calibrate for the full range of the instrument, 2 or 3 calibration curves are analyzed in succession. The instrument software will link up to 3 overlapping calibration curves. Each calibration curve should be spiked with at least five differing amounts of the following standards:

11.2.2.1.1 High-range curve: CaCO<sub>3</sub> (12% carbon), purchased powder.

11.2.2.1.2 Low-range curve: 1000 mg/L KHP (0.1% carbon), dilute 0.2128 g KHP to 100 mL with DI water.

11.2.2.1.3 Mid-range curve (if needed): 10,000 mg/L KHP (1% carbon), dilute 2.128 g KHP to 100mL with DI water.

11.2.2.2 Change desiccant daily. Change scrubbers and oxygen tank as needed. Make sure there is at least 500 psi of oxygen available for a full run of 20 samples.

11.2.2.3 Open flow on the oxygen tank. Turn the power “on” to each of the three instrument modules, and initialize the instrument. The instrument’s pump will engage once the 1100°C operating temperature is reached. Allow the instrument to sit idle at operating temperature to allow for the IR detector to stabilize. Adjust the pump flow as needed to maintain a flow reading of around 100 for the “Actual – swinging in” reading in the status window.

11.2.2.4 Set up a sequence by opening “Analysis Sequence – new” in the “Sequence” tab. Name the run as the date of analysis. Add the sample names and QC in the correct order of analysis. Enter all sample weights. Add around 25 mg of calcium carbonate to each CCV boat. CCB boats are left empty. Spike each MS/MSD with around 25 mg of calcium carbonate. Add the spike amount to the bench sheet.

11.2.2.5 Place all sample boats on the autosampler, matching their autosampler position on to the correct assigned analysis position. The first position is labeled as “Clean” and will burn off the carbon on the hook before reading samples.

11.2.2.6 Approve the samples and weights by selecting the “Enable all sequence entries” tab and choose “OK” to close the window.

11.2.2.7 Open the “Start Measurement” icon. Select the name/date of the current run, select “OK” and then select “Start Measurement”.

11.2.2.8 Once the run is complete, select all samples from the run in the “Results” window and print.

## 12) QA/QC Requirements

STANDARD OPERATING PROCEDURE	Total Organic Carbon in Soil
	GEN-ASTM, Rev. 14.0
ALS   Environmental - Kelso	Effective: 10/30/2020
	Page 8 of 13

- 12.1 This method shall operate under the formal Quality Assurance Program established at ALS and must maintain records that define the quality of data that is generated. Data shall be compared to established criteria in order to determine if the results of the analyses meet the performance characteristics of the method. It is required that an initial demonstration of capability and periodic analysis of laboratory reagent blanks, laboratory fortified blanks, and other QC solutions as a continuing check on performance. The accuracy and precision of the procedure must be validated *before* analyses of samples begin, or whenever significant changes to the procedures have been made.
- 12.2 Initial Precision and Recovery Validation
- 12.2.1 Four LCS's are prepared and analyzed. The RSD should be <20% and average recovery must be within LCS recovery limits (see laboratory DQO Tables).
- 12.3 Method Detection Limits and Method Reporting Limits
- 12.3.1 A method detection limit (MDL) study must be undertaken before analysis of samples can begin. To establish detection limits that are precise and accurate, the analyst must perform the following procedure. Analyze a minimum of seven spiked blank replicates at a level near the MRL. Follow the procedures starting in Section 11 to analyze the samples. Refer to *Performing and Documenting Method Detection Limit Studies and Establishing Limits of Detection and Quantification*. The MDL study must be performed or verified periodically, as required by the SOP.
- 12.3.2 Calculate the average concentration found (x) in the sample concentration, and the standard deviation of the concentrations for each analyte. Calculate the MDL for each analyte using the correct T value for the number of replicates.
- 12.3.3 Limits of Quantification (LOQ)
- 12.3.4 The laboratory establishes a LOQ for each analyte as the lowest reliable laboratory reporting concentration or in most cases the lowest point in the calibration curve which is less than or equal to the desired regulatory action levels, based on the stated project requirements. Analysis of a standard or extract prepared at the lowest point calibration standard provides confirmation of the established sensitivity of the method. The LOQ recoveries should be within 50-150% of the true values to verify the data reporting limit. Refer to *Performing and Documenting Method Detection Limit Studies and Establishing Limits of Detection and Quantification*.
- 12.3.5 The Method Reporting Limits (MRLs) used at ALS are the routinely reported lower limits of quantitation which take into account day-to-day fluctuations in instrument sensitivity as well as other factors. These MRLs are the levels to which ALS routinely reports results in order to minimize false positive or false negative results. The MRL is normally two to ten times the method detection limit.
- 12.4 Ongoing QC Samples required are described in the ALS Kelso Quality Assurance Manual and in the SOP *Sample Batches* (ADM-BATCH). Additional QC Samples may be required in project specific quality assurance plans (QAPP). For example projects managed under the DoD ELAP must follow requirements defined in the DoD *Quality Systems Manual for Environmental Laboratories*. General QA requirements for DoD QSM are defined in the laboratory SOP *Department of Defense Projects - Laboratory Practices and Project Management* (ADM-DOD).
- 12.5 The QC criteria discussed in the following sections are summarized in Table 1.

- 12.5.1 Laboratory Control Sample (LCS)- An LCS must be analyzed with each batch of 20 or fewer samples.
- 12.5.1.1 ASTM Method D4129-05, PSEP and Lloyd Kahn: analyze 50 mg of the purchased standard. The acceptance criteria for the LCS are listed in Table 1.
- 12.5.1.2 EPA 9060: analyze 250 mg of the purchased standard. The acceptance criteria for the LCS are listed in Table 1.
- 12.5.2 Method Blank (MB) - Analyze one method blank per batch of 20 or fewer samples. Add one to two drops of 10% HCl to an empty boat and place the boat in a 70°C oven to dry.
- 12.5.2.1 ASTM Method D4129-05, PSEP and Lloyd Kahn: Method Blank must be <0.05% carbon.
- 12.5.2.2 EPA 9060: Method Blank must be < 0.1% carbon.
- 12.5.3 Continuing Calibration Verification (CCV) A CCV must be analyzed every ten samples, bracketing the beginning and the end of each analytical run.
- 12.5.3.1 ASTM Method D4129-05 PSEP and Lloyd Kahn: analyze 10mg urea. The CCV acceptance recovery is 90-110%.
- 12.5.3.2 EPA 9060: 25 mg of CaCO<sub>3</sub>. The CCV acceptance recovery is 90-110%.
- 12.5.4 Continuing Calibration Blank (CCB) - A CCB must be analyzed following every CCV.
- 12.5.5 Sample Replicates (Duplicates and Triplicates):
- 12.5.5.1 ASTM Method D4129 and EPA 9060: One duplicate sample per batch of 20 or fewer samples.
- 12.5.5.2 TOC analysis by PSEP methodology requires one sample to be analyzed in triplicate per batch of 20 or fewer samples.
- 12.5.5.3 Lloyd Kahn: One sample must be analyzed in quadruplicate per batch of twenty or fewer samples.
- 12.5.6 Matrix Spike/Matrix Spike Duplicate (MS/MSD)) - shall be analyzed with each batch of 20 or fewer samples.
- 12.5.7 Refer to Table 1 and the ALS Kelso DQO Table for up to date acceptance criteria and corrective actions

### 13) Data Reduction and Reporting

#### 13.1 Data Review and Assessment

- 13.1.1 It is the analyst's responsibility to review analytical data to ensure that all quality control requirements have been met for each analytical run. Results for QC analyses are calculated and recorded as specified in this SOP. Average, RPD, spike level and spike recovery are entered on the analytical spreadsheet for corresponding samples. All data will be initialed, dated and attached to required data quality worksheet.
- 13.1.2 Following primary data interpretation and calculations, all data is reviewed by a secondary analyst. Following generation of the report, the report is also reviewed. Refer to the *SOP for Laboratory Data Review Process* (ADM-DREV) for

details. The person responsible for final review of the data report and/or data package should assess the overall validity and quality of the results and provide any appropriate comments and information to the Project Manager for inclusion in the report narrative.

### 13.2 Data Reporting

13.2.1 Refer to the SOP for *Data Reporting and Report Generation* (ADM-RG) for reporting guidelines.

13.2.2 For final reports, the method is reported as ASTM Method D4129 Modified or EPA Method 9060A Modified.

13.2.3 ASTM Method D4129-05, PSEP and Lloyd Kahn: Calculate % carbon as follows:

$$\%Carbon = \frac{(Gross\ reading - baseline\ \mu g)(0.1)}{mg\ sample\ analyzed}$$

13.2.4 Total organic carbon is reported as % carbon, normally on a dry weight basis. Results may be reported on an as received basis.

13.2.5 For duplicate analyses, calculate relative percent difference as follows:

$$RPD = \frac{S_1 - S_2}{Avg} * 100$$

Where  $S_1$  = Sample with higher value

$S_2$  = Sample with lower value

$Avg$  = Average of the two sample values.

13.2.6 Calculate percent recovery as follows:

$$\%R = \frac{X - X_i}{TV} * 100$$

Where  $X$  = Concentration of the analyte recovered

$X_i$  = Concentration of unspiked analyte

$TV$  = True Value of amount spiked

13.2.7 The analyst enters data directly into ALSLIMS templates. An Analytical Results Summary is generated for that analytical batch showing all QC and sample results. After primary and secondary review, final reports are generated in ALSLIMS or Labcoat™ by compiling the SMO login, sample prep database, instrument date, and client-specified report requirements (when specified). The forms generated may be ALS standard reports, DOD, or client-specific reports. The compiled data from LIMS is also used to create EDDs.

13.2.8 As an alternative, reports are generated using [REDACTED] templates located in R:\Wet\FORMS\DOD. The analyst should choose the appropriate form and QC pages to correspond to required tier level and deliverables requirements. The results are then transferred, by hand or electronically, to the templates.

## 14) Method Performance

- 14.1 The accuracy and precision of the procedure must be validated before analysis of samples begins, or whenever significant changes to the procedures have been made. To do this, four LCS aliquots are prepared and analyzed. The average percent recovery must meet the laboratory control sample acceptance limits.
- 14.2 The method detection limit (MDL) is established using the procedure described in the *Performing Method Detection Limit Studies and Establishing Limits of Detection and Quantification*. Method Reporting Limits are established for this method based on MDL studies and as specified in the ALS Quality Assurance Manual.

## 15) Pollution Prevention and Waste Management

- 15.1 The laboratory will comply with all Federal, State and local regulations governing waste restrictions as specified in the ALS Lab Waste Management Plan.

## 16) Corrective Actions for Out-of-Control Data or Unacceptable Data

- 16.1 Refer to the SOP for *Nonconformance and Corrective Action Procedures* (ADM-NCAR) for procedures for corrective action. Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

## 17) Training

- 17.1 All analysts performing this analysis are required to read and understand this SOP.
- 17.2 Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

## 18) References and Related Documents

### 19) Summary of Changes

Revision Number	Effective Date	Document Editor	Description of Changes
14.0	10/30/2020	T. Caron	Reformatted SOP to current ALS format. Minor typographical, grammatical, and formatting changes. Updated signatories. Section 7.2: Updated sample storage and holding time (frozen samples).

### 20) Attachments, Tables, and Appendices

20.1 Table 1: Summary of Corrective Actions.

**Table 1**

<b>Summary of Corrective Actions</b>				
<b>Method Reference</b>	<b>Control</b>	<b>Specification and Frequency</b>	<b>Acceptance Criteria</b>	<b>Corrective Action</b>
ASTM D4129 PSEP Lloyd Kahn EPA 9060A	CCV	Verify calibration by analyzing prior to samples, after every 10 analysis and after the last sample	±10%	Re-analyze all samples affected.
ASTM D4129 PSEP Lloyd Kahn EPA 9060A	LCS	Include with each analysis batch (up to 20 samples)	See DQO Tables	Re-analyze all samples affected.
ASTM D4129 PSEP Lloyd Kahn EPA 9060A	Method Blank	Include with each analysis batch (up to 20 samples)	< 0.05%	If target exceeds 0.05%, clean boats and re-analyze.
ASTM D4129 PSEP Lloyd Kahn EPA 9060A	Matrix Spike/Matrix Spike Duplicate	Include with each analysis batch (up to 20 samples)	See DQO Tables	Evaluate data to determine if there is a matrix effect or analytical error
ASTM D4129 EPA 9060A	Sample Duplicates	Include with each analysis batch (up to 20 samples)	≤ 20 % RPD	Re-homogenize and re-analyze if result is > 5 X the MRL
PSEP	Sample Triplicate	Include with each analysis batch (up to 20 samples)	≤ 20 % RSD	Re-homogenize and re-analyze if result is > 5 X the MRL
Lloyd Kahn	Sample Quadruplicate	Include with each analysis batch (up to 20 samples)	≤ 20 % RPD	Re-homogenize and re-analyze if result is > 5 X the MRL

	STANDARD OPERATING PROCEDURE	Soil pH Determination
	ALS   Environmental - Kelso	GEN-pHS Rev. 17.0
		Effective: 5/31/2019
		SOP Review: 2/17/2021
		Page 2 of 10

## 1) Scope & Applicability

- 1.1 This procedure is used to determine pH in soil, solid, and certain waste samples using EPA Methods 9045C and 9045D.
- 1.2 When used to determine pH in multiphase wastes, the procedure is applicable if the aqueous phase constitutes less than 20% of the total volume of the waste.
- 1.3 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DOD ELAP. QC requirements defined in the SOP *Department of Defense Projects - Laboratory Practices and Project Management* (ADM-DOD5) may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 The pH is determined by potentiometric measurement of a soil slurry or aqueous solution using a standard combination glass pH electrode and pH meter
- 2.2 The procedure uses methodology described in EPA Methods 9045C, 9045D, WDOE Test Method, and Oregon State Soil Methods.

## 3) Definitions

- 3.1 For laboratory definitions applicable to most analyses, refer to the SOP for [Sample Batches](#).

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. The department supervisor/manager or designee performs final review and sign-off of the data.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency as referenced in *Employee Training and Orientation*, ADM-TRAIN.

## 5) Interferences

- 5.1 Samples with extreme pH results may give incorrect readings on the meter. Samples with a high sodium concentration and pH > 10 can cause error. Using a "low sodium error" electrode (such as Orion 8165, 8172 or equivalent) eliminates this issue to a pH of 12. If the pH is greater than 12, the sodium content of the sample may need to be determined and the pH result may need correction. Strong acid solutions with pH < 1 may give incorrect high pH readings.
- 5.2 Samples containing oil may coat the electrode and cause a sluggish response or inaccurate reading. If an electrode becomes coated with a material which cannot be rinsed off, the electrode can be cleaned with an ultrasonic bath, be washed with

	STANDARD OPERATING PROCEDURE	Soil pH Determination
	ALS   Environmental - Kelso	GEN-pHS Rev. 17.0
		Effective: 5/31/2019
		SOP Review: 2/17/2021
		Page 3 of 10

detergent and rinsed then placed in 1:1 HCl so that the lower third of the electrode is submerged, then rinsed thoroughly with water.

5.3 Temperature fluctuations will cause instrument errors.

## 6) Safety

6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.

## 7) Sample Collection, Containers, Preservation, and Storage

7.1 Sample bottles can either be glass or plastic and must be thoroughly cleaned and rinsed prior to use.

7.2 Samples must be stored refrigerated at 4°C ( $\pm$  2°C). Although there is no holding time established for soils, samples should be analyzed as soon as possible.

## 8) Apparatus and Equipment

8.1 Orion Dual Star pH meter, SN E09484, or equivalent.

8.2 Combination electrode for pH with temperature probe, such as Orion 8165, 8172 or equivalent.

8.3 Conductivity jars, 50 ml.

8.4 Analytical balance capable of weighing 0.1 g.

8.5 Paint filters.

8.6 Erlenmeyer flasks, 250 ml.

8.7 Water bath capable of maintaining a constant temperature of 25°C. One large for all samples and buffers and one smaller bath for analyzing samples at 25°C  $\pm$  1°C.

8.8 Standard stir plate and submersible stir plate and stir bars.

8.9 Eight ounce or 16 ounce juice bottles and caps.

8.10 Wrist action shaker..

## 9) Standards, Reagents, and Consumable Materials

9.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Standards, reagents and consumable material documentation shall indicate traceability to purchased neat materials or compounds. Refer to the SOP *Reagent/Standards Login and Tracking* (ADM-RLT) for the complete procedure and documentation requirements.

9.2 All stocks, working solutions and sample dilutions should be prepared using deionized water (DI) conforming to ASTM Type I or ASTM Type II reagent water. For more information on reagent water generation, refer to the related SOP, Operation and Maintenance of Laboratory Reagent Water Systems.

9.3 Standards

	STANDARD OPERATING PROCEDURE	Soil pH Determinaiton
	ALS   Environmental - Kelso	GEN-pHS Rev. 17.0
		Effective: 5/31/2019
		SOP Review: 2/17/2021
		Page 4 of 10

- 9.4 pH buffers: 1.00, 4.00, 7.00, 10.00, 12.45, (true value of buffers at 25° C).
- 9.5 Commercially available solutions should be validated and traceable to NIST standards and are recommended for routine use..

## 10) Preventive Maintenance

- 10.1 The probe should contain filling solution past the coils to ensure accurate readings. Filling solution should be a non-AgCl containing solution.
- 10.2 Cleaning the probe
  - 10.2.1 The probe should be emptied and refilled with filling solution once a week.
  - 10.2.2 The glass bulb should be cleaned every other week, or more, by placing it in a beaker with approximately 40 ml of 0.1N HCl and allowed to sit while stirring for approximately 5 minutes. Then rinse the probe with DI water 3 times and blot with a Kimwipe®.
  - 10.2.3 f the coils are no longer orange it means the electrode's ion reservoir is empty and it needs to be replaced.

## 11) Procedure

- 11.1 Calibration
  - 11.1.1 All buffers are placed in the conductivity jars and stored in the large 25° C waterbath. All readings need to be within 1° C of the buffered temperatures.
  - 11.1.2 Buffer in conductivity jars to be replaced with buffer from the primary container daily.
  - 11.1.3 Once a manufacture's bottle of buffer is open it's good for 3 months, because it becomes contaminated with carbon dioxide.
  - 11.1.4 Perform calibration daily. Record calibration; buffer checks and buffer temperatures in instrument logbook or benchsheet with date and analyst's initials.
  - 11.1.5 The slope of the calibration points should be between 92 and 102% or within the range set by the probe manufacturer. The meter displays the slope of calibration.
  - 11.1.6 If the slope exceeds the above end points either the buffer(s) is contaminated or the probe is no longer functioning properly.
  - 11.1.7 Replace buffers, rewarm and then re calibrate.
  - 11.1.8 Clean the probe with 0.1 N HCl, rinse and blot dry with a Kimwipe®.
- 11.2 Orion Dual Star pH Meter Calibration
  - 11.2.1 Select "cal" (f2 key)

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Soil pH Determinaiton
	GEN-pHS Rev. 17.0
	Effective: 5/31/2019
	SOP Review: 2/17/2021
	Page 5 of 10

- 11.2.2 Rinse electrode and immerse electrode into the 4.00 pH solution.
  - 11.2.3 Select "start" (f3 key).
  - 11.2.4 When stable, change the default value to 4.00.
  - 11.2.5 Select "accept" (f2 key).
  - 11.2.6 Select "next" (f2 key).
  - 11.2.7 Rinse electrode and immerse into the 7.00 pH solution.
  - 11.2.8 Select "start" (f3 key).
  - 11.2.9 When stable, select "accept"(f2 key).Default value is 7.00.
  - 11.2.10 Select "next" (f2 key).
  - 11.2.11 Rinse electrode and immerse into the 10.00pH solution.
  - 11.2.12 Select "start" (f3 key).
  - 11.2.13 When stable, change the default value to 10.00.
  - 11.2.14 Select "accept" (f2 key).
  - 11.2.15 Add 1.00 and 12.45 pH buffers if needed, remembering to change the default value to the true value.
  - 11.2.16 Once all required calibration buffers have been added, select "cal done" (f3 key).
  - 11.2.17 Record "average slope value", buffer temperatures and analysis times on the pH bench sheet.
  - 11.2.18 Select "log/print"(f2 key) to save calibration data and exit calibration screen.
  - 11.2.19 To calibrate the "channel2" electrode, select the "channel "button to switch to channel 2 and repeat the above steps.
  - 11.2.20 **Note:** Initial calibration is performed using the 4.00, 7.00, and 10.00 buffers. If any subsequent sample pH is outside the calibration range (greater than 10.00 or less than 4.00), the 1.00 and/or 12.45 buffers are added to the calibration and the applicable samples are reanalyzed.
  - 11.2.21 Following the instrument calibration, a pH 4.00, 7.00 or 10.00 check standard is analyzed. The acceptance criterion is  $\pm 0.05$  pH units of the true value. If the standard is outside of these acceptance limits, the buffer is rechecked once. If it is still outside the  $\pm 0.05$  pH unit limit, the instrument is recalibrated. The same check standard is repeated every 10 pH measurements and must meet the same acceptance criteria. When the sample pH is  $\geq 12.00$  analyze the pH 12.45 buffer as the buffer check standard. If a check fails, reanalyze the check. If it fails again, recalibrate instrument, perform check analysis, and reanalyze all samples back to the previous passing check.
- 11.3 Soil samples preparation for EPA Methods 9045C and 9045D.

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Soil pH Determination
	GEN-pHS Rev. 17.0
	Effective: 5/31/2019
	SOP Review: 2/17/2021
	Page 6 of 10

- 11.3.1 Weigh out 10g of soil into a beaker. Add 10mL of reagent water, cover, and shake samples for 30 minutes on the wrist action shaker. Alternative sample volumes may be used as long as soil: water ratios remain the same. Additional dilutions may be performed if working with hygroscopic soils and salts, or other problematic matrices.
- 11.3.2 Let the soil suspension stand for 1 hour to allow for settling. Alternatively, filter or centrifuge off the aqueous phase for pH determination.
- 11.3.3 Setup electrodes in clamps so that when the electrode is lowered into the beaker, the electrode will be immersed just deep enough in the supernatant solution to establish a good electrical contact through the ground-glass joint or fiber capillary hole. Immerse the electrode in samples in this manner.
- 11.4 Waste material preparation for EPA Methods 9045C and 9045D.
  - 11.4.1 Wastes may be solids, sludges, or non-aqueous liquids. For multi-phase wastes by method 9045D, a determination of the percentage of the sample that is non-aqueous must be made. This can be calculated from a % solids determination. If the non-aqueous phase is > 20%, continue with this section. If the non-aqueous phase is < 20%, analyze the sample by EPA Method 9040C see also SOP GEN-pHW.
  - 11.4.2 Weigh out 20g of waste sample into a beaker. Add 20mL of reagent water, cover, and shake samples for 30 minutes on the wrist action shaker. Alternative sample volumes may be used as long as solid::water ratios remain the same. Additional dilutions may be performed if working with hygroscopic soils and salts, or other problematic matrices.
  - 11.4.3 Let the waste suspension stand for 15 minutes to allow for settling. Alternatively, filter or centrifuge off the aqueous phase for pH determination.
  - 11.4.4 If the waste absorbs all the reagent water, begin the test again with 20g waste and 40mL of water.
  - 11.4.5 If the supernatant is multi-phasic, decant the oily phase and perform the pH determination on the aqueous phase.
  - 11.4.6 Setup electrodes in clamps so that when the electrode is lowered into the beaker, the electrode will be immersed just deep enough in the supernatant solution to establish a good electrical contact through the ground-glass joint or fiber capillary hole. Immerse the electrode in samples in this manner.
- 11.5 Sample preparation for Washington DOE Test Method.
  - 11.5.1 Weigh three, 50.0g aliquots of each sample into either 3, 8-ounce or 3, 16-ounce juices bottles and add 50mL of D.I. water to each and cap tightly. Each sample is analyzed in triplicate.
  - 11.5.2 Place all bottles on the wrist action shaker for 30 minutes. The speed of the shaker should be adjusted so that the sample and water have maximum

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Soil pH Determinaiton
	GEN-pHS Rev. 17.0
	Effective: 5/31/2019
	SOP Review: 2/17/2021
	Page 7 of 10

contact time however the shaking action should not be so vigorous as to cause absorption of CO<sub>2</sub> into the sample.

11.5.3 Filter the liquid through a paint filter into a clean conductivity jar for analysis.

#### 11.6 Oregon State Soil Methods sample preparation

11.6.1 Weigh 20.0g of soil into a beaker and add 40mL of D.I. water.

11.6.2 Stir the suspension 2-3 times over a 30-minute period.

11.6.3 Analyze the supernatant.

#### 11.7 Sample Analysis

11.7.1 Rinse and blot electrode, then immerse into the sample. Press pH and record the pH when stabilized, record the temperature to the nearest °C. Remove electrodes from sample after each measurement and rinse 3 times with D.I. water.

11.7.2 Regardless of the method employed, all pH readings must be within 2°C of the temperature of the buffer solutions.

11.7.3 If the pH of the sample is  $\geq 11.00$  control the temperature of the samples to  $25^{\circ}\text{C} \pm 1^{\circ}\text{C}$ .

## 12) QA/QC Requirements

12.1 This method shall operate under the formal Quality Assurance Program established at ALS and must maintain records that define the quality of data that is generated. Data shall be compared to established criteria in order to determine if the results of the analyses meet the performance characteristics of the method. It is required that an initial demonstration of capability and periodic analysis of laboratory reagent blanks, laboratory fortified blanks, and other QC solutions as a continuing check on performance. The accuracy and precision of the procedure must be validated *before* analyses of samples begin, or whenever significant changes to the procedures have been made.

12.2 A buffer check is analyzed after every 10 readings. For buffer checks, use either pH 4.00 or 10.00, choosing whichever standard brackets the majority of the previous samples with pH 7.00. The buffer check should be within 0.05 pH units of the true value.

12.3 A Laboratory Control Sample (LCS) is analyzed at a frequency of one per 20 samples. The LCS is a purchase reference material. The Certified Value and Acceptance Limits listed on the vendor's Certificate of Analysis are to be used to evaluate the LCS recovery. Analyze the LCS prior to the sample set. The LCS is prepared identically to associated samples and documented on the analytical. Worksheet If the LCS is outside of the acceptance limits, recalibrate the instrument.

12.4 A duplicate sample is analyzed at a frequency of 10% of the samples, with acceptance criteria of 10% RPD between the two readings. If the duplicate is outside of these

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Soil pH Determinaiton
	GEN-pHS Rev. 17.0
	Effective: 5/31/2019
	SOP Review: 2/17/2021
	Page 8 of 10

limits, the sample is reanalyzed. Duplicates are documented on the benchsheet. For duplicate analyses, calculate relative percent difference as follows:

$$RPD = \frac{S_1 - S_2}{Avg} * 100$$

Where S1 = Sample with higher value  
S2 = Sample with lower value  
Avg. = Average of the two sample values

- 12.5 For DOE/pH, all samples are analyzed in triplicate and the logarithmic average is reported.
- 12.6 Sum the antilog of the three pH readings obtained in section 11.5, divide by 3 then take the log.

Example:

Three pH readings obtained: 1.5    1.6    2.5

antilog(1.5) + antilog(1.6) + antilog(2.5) =  
31.62 + 39.81 + 316.23 = 387.66  
387.66 ÷ 3 = 129.22  
log(129.22) = 2.11  
pH(average) = 2.11.

### 13) Data Reduction and Reporting

#### 13.1 Data Review and Assessment

13.1.1 Following primary data interpretation and calculations, all data is reviewed by a secondary analyst. Following generation of the report, the report is also reviewed. Refer to the *SOP for Laboratory Data Review Process (ADM-DREV)* for details. The person responsible for final review of the data report and/or data package should assess the overall validity and quality of the results and provide any appropriate comments and information to the Project Manager for inclusion in the report narrative.

13.1.2 It is the analyst's responsibility to review analytical data to ensure that all quality control requirements have been met for each analytical run. Results for QC analyses are calculated and recorded as specified in this SOP. Average, RPD, spike level and spike recovery are entered on the analytical spreadsheet for corresponding samples. All data will be initialed, dated and attached to required data quality worksheet.

#### 13.2 Reporting

13.2.1 Refer to the SOP for *Data Reporting and Report Generation (ADM-RG)* for reporting guidelines

	STANDARD OPERATING PROCEDURE	Soil pH Determinaiton
	ALS   Environmental - Kelso	GEN-pHS Rev. 17.0
		Effective: 5/31/2019
		SOP Review: 2/17/2021
		Page 9 of 10

13.2.2 The analyst enters data directly into ALSLIMS templates. An Analytical Results Summary is generated for that analytical batch showing all QC and sample results. After primary and secondary review, final reports are generated in ALSLIMS by compiling the SMO login, sample prep database, instrument date, and client-specified report requirements (when specified). The forms generated may be ALS standard reports, DOD, or client-specific reports. The compiled data from LIMS is also used to create EDDs.

13.2.3 The pH is reported as pH units. Values are reported to 0.01 pH units.

13.2.4 The benchsheets should be in use at all times during pH analysis.

#### 14) Method Performance

14.1 This method was validated through single laboratory studies of accuracy and precision. Refer to the reference method for additional method performance data available.

#### 15) Pollution Prevention and Waste Management

15.1 It is the laboratory's practice to minimize the amount of solvents, acids and reagent used to perform this method wherever feasible. Standards are prepared in volumes consistent with methodology and only the amount needed for routine laboratory use is kept on site. The threat to the environment from solvent and reagents used in this method can be minimized when recycled or disposed of properly.

15.2 The laboratory will comply with all Federal, State and local regulations governing waste restrictions as specified in the ALS Lab Waste Management Plan.

#### 16) Corrective Actions for Out-of-Control Data or Unacceptable Data

16.1 Refer to the SOP for *Nonconformance and Corrective Action Procedures* (ADM-NCAR) for procedures for corrective action.

16.2 Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

#### 17) Training

17.1 All analysts performing this analysis are required to read and understand this SOP.

17.2 Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

17.3 It is required that an initial demonstration of capability and periodic analysis of laboratory reagent blanks, laboratory fortified blanks, and other QC solutions as a continuing check on performance.

		Page 2 of 8

## 1) Scope & Applicability

- 1.1 This procedure is used to measure the pH of aqueous samples using SM 4500-H+B-2011, EPA 150.1 and EPA 9040C.
- 1.2 The 9040C procedure may be used to determine pH in most aqueous samples including multiphase wastes where the aqueous phase constitutes 20% or more of the total volume of the waste. The corrosivity of concentrated acids and bases cannot be measured. The pH measurement requires some water content.
- 1.3 The EPA 150.1 procedure is applicable to drinking, surface, and saline waters, domestic and industrial wastes and acid rain (atmospheric deposition).
- 1.4 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DOD ELAP. QC requirements defined in the SOP *Department of Defense Projects - Laboratory Practices and Project Management* (ADM-DOD/ADM-DOD5) may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 The pH is determined by potentiometric measurement, using a standard combination glass pH electrode and a pH/specific ion meter. The measuring device is calibrated using a series of standard solutions of known pH.

## 3) Definitions

- 3.1 For laboratory definitions applicable to most analyses, refer to the SOP for [Sample Batches](#).

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. The department supervisor/manager or designee performs final review and sign-off of the data.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency as referenced in *Employee Training and Orientation*, ADM-TRAIN.

## 5) Interferences

- 5.1 Samples with extreme pH results may give incorrect readings on the meter. Samples with a high sodium concentration and pH > 10 can cause error. Using a "low sodium error" electrode (such as Orion 8165, 8172 or equivalent) eliminates this issue to a pH of 12. If the pH is greater than 12, the sodium content of the sample may need to be determined and the pH result may need correction. Strong acid solutions with pH < 1 may give incorrect high pH readings.

	STANDARD OPERATING PROCEDURE	Water pH Determination
	ALS   Environmental - Kelso	GEN-pHW Rev. 17.0
		Effective: 2/18/2021
		SOP Review: 2/17/2021
		Page 3 of 8

- 5.2 Samples containing oil may coat the electrode and cause a sluggish response or inaccurate reading.
- 5.3 For acid rain samples it is most important that the magnetic stirrer is not used. Instead, swirl the sample gently for a few seconds after the introduction of the electrode(s). Allow the electrode(s) to equilibrate. The air-water interface should not be disturbed while measurement is being made. If the sample is not in equilibrium with the atmosphere, pH values will change as the dissolved gases are either absorbed or desorbed. Record sample pH and temperature.

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Samples may be collected in plastic bottles and should not be preserved.
- 7.2 Samples should be stored at 0-6°C.
- 7.3 Reference methods state that samples should be analyzed “immediately” or “Analyzed as soon as possible preferably in the field at the time of sampling.” Samples submitted to the laboratory should be analyzed as soon as possible. Those analyzed later than 24 hours from receipt should be flagged as exceeding holding time.

## 8) Apparatus and Equipment

- 8.1 Orion Dual Star pH meter, SN E09484, or equivalent.
- 8.2 Combination electrode for pH with temperature probe, such as Orion 8157 or equivalent.
- 8.3 Conductivity jars, 50 ml.
- 8.4 Water bath capable of maintaining a constant temperature of 25°C. One large for all samples and buffers and one smaller bath for analyzing samples at 25°C ± 1°C.
- 8.5 Standard stir plate and submersible stir plate and stir bars

## 9) Standards, Reagents, and Consumable Materials

- 9.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Standards, reagents and consumable material documentation shall indicate traceability to purchased neat materials or compounds. Refer to the SOP *Reagent/Standards Login and Tracking*, for the complete procedure and documentation requirements.
- 9.2 All stocks, working solutions and sample dilutions should be prepared using deionized water (DI) conforming to ASTM Type I or ASTM Type II reagent water. For more information on reagent water generation, refer to the related SOP, Operation and Maintenance of Laboratory Reagent Water Systems.
- 9.3 pH buffers: 1.00, 4.00, 7.00, 10.00, 12.45, (true value of buffers at 25° C).

STANDARD OPERATING PROCEDURE

ALS | Environmental - Kelso

Water pH Determinaiton

GEN-pHW Rev. 17.0

Effective: 2/18/2021

SOP Review: 2/17/2021

Page 4 of 8

9.4 Commercially available solutions should be validated and traceable to NIST standards and are recommended for routine use.

## 10) Preventive Maintenance

10.1 The probe should contain filling solution past the coils to ensure accurate readings. Filling solution should be a non-AgCl containing solution.

10.2 Cleaning the probe.

10.2.1 The glass bulb should be cleaned every other week, or more, by placing it in a beaker with approximately 40 ml of 0.1N HCl and allowed to sit while stirring for approximately 5 minutes. Then rinse the probe with DI water 3 times and blot with a Kimwipe®.

10.2.2 If the coils are no longer orange it means the electrode's ion reservoir is empty and it needs to be replaced.

## 11) Procedure

11.1 Calibration

11.1.1 All buffers are placed in the conductivity jars and stored in the large 25° C waterbath. All readings need to be within 1° C of the buffered temperatures.

11.1.2 Buffer in conductivity jars to be replaced with buffer from the primary container daily.

11.1.3 Once a manufacture's bottle of buffer is open it's good for 3 months, because it becomes contaminated with carbon dioxide.

11.1.4 Perform calibration daily. Record calibration; buffer checks and buffer temperatures in instrument logbook or benchsheet with date and analyst's initials.

11.1.5 The slope of the calibration points should be between 92 and 102% or within the range set by the probe manufacturer. The meter displays the slope of calibration.

11.1.6 If the slope exceeds the above end points either the buffer(s) is contaminated or the probe is no longer functioning properly.

11.1.6.1 Clean the probe, replace buffers, rewarm and then re calibrate.

11.1.6.2 .If the slope still fails after cleaning, replace the probe.

11.2 Orion Dual Star pH meter Calibration

11.2.1 Select "cal" (f2 key)

11.2.2 Rinse electrode and immerse electrode into the 4.00 pH solution.

11.2.3 Select "start" (f3 key).

11.2.4 When stable, change the default value to 4.00.

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Water pH Determination
	GEN-pHW Rev. 17.0
	Effective: 2/18/2021
	SOP Review: 2/17/2021
	Page 5 of 8

- 11.2.5 Select "accept" (f2 key).
- 11.2.6 Select "next" (f2 key).
- 11.2.7 Rinse electrode and immerse into the 7.00 pH solution.
- 11.2.8 Select "start" (f3 key).
- 11.2.9 When stable, select "accept"(f2 key).Default value is 7.00.
- 11.2.10 Select "next" (f2 key).
- 11.2.11 Rinse electrode and immerse into the 10.00pH solution.
- 11.2.12 Select "start" (f3 key).
- 11.2.13 When stable, change the default value to 10.00.
- 11.2.14 Select "accept" (f2 key).
- 11.2.15 Add 1.00 and 12.45 pH buffers if needed, remembering to change the default value to the true value.
- 11.2.16 Once all required calibration buffers have been added, select "cal done" (f3 key).
- 11.2.17 Record "average slope value", buffer temperatures and analysis times on the pH bench sheet.
- 11.2.18 Select "log/print"(f2 key) to save calibration data and exit calibration screen.
- 11.2.19 To calibrate the "channel2" electrode, select the "channel "button to switch to channel 2 and repeat the above steps.
- 11.2.20 **Note:** Initial calibration is performed using the 4.00, 7.00, and 10.00 buffers. If any subsequent sample pH is outside the calibration range (greater than 10.00 or less than 4.00), the 1.00 and/or 12.45 buffers are added to the calibration and the applicable samples are reanalyzed.
- 11.2.21 Following the instrument calibration, a pH 4.00, 7.00 or 10.00 check standard is analyzed. The acceptance criterion is  $\pm 0.05$  pH units of the true value. If the standard is outside of these acceptance limits, the buffer is rechecked once. If it is still outside the  $\pm 0.05$  pH unit limit, the instrument is recalibrated. The same check standard is repeated every 10 pH measurements and must meet the same acceptance criteria. When the sample pH is  $\geq 12.00$  analyze the pH 12.45 buffer as the buffer check standard. If a check fails, reanalyze the check. If it fails again, recalibrate instrument, perform check analysis, and reanalyze all samples back to the previous passing check.

### 11.3 Sample Preparation

- 11.3.1 Place enough sample or buffer to cover the tip of the pH probe into a conductivity jar. Cap the jar and place it into the 25°C water bath. Generally the samples or buffers will reach 25°C in about 30 minutes, however, if the sample is colder it may require more time in the water bath to reach 25°C.

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Water pH Determination
	GEN-pHW Rev. 17.0
	Effective: 2/18/2021
	SOP Review: 2/17/2021
	Page 6 of 8

11.3.2 For multi-phase wastes a determination of the percentage of the sample that is aqueous must be made. This can be calculated from a %solids determination. If the aqueous phase is > 20%, continue with the analysis. If the aqueous phase is < 20%, analyze the sample by the soil procedure (SOP GEN-pHS).

#### 11.4 Sample Analysis

11.4.1 For SM 4500-H+B-2011: Single analysis and a Duplicate Sample every ten samples.

11.4.2 For 9040C and 150.1 all samples must be analyzed in duplicate and the measured pH values must be < 0.1 pH units between the two readings. If the duplicate is outside of this limit, the sample is reanalyzed. Duplicates are documented on the benchsheet.

11.4.3 Rinse and blot electrode, then immerse into the sample. Press pH and record the pH when stabilized, record the temperature to the nearest °C. Remove electrodes from sample after each measurement and rinse 3 times with D.I. water.

11.4.4 All pH readings must be within 2°C of the temperature of the buffer solutions.

11.4.5 If the pH of the sample is  $\geq 11.00$  control the temperature of the samples to  $25^{\circ}\text{C} \pm 1^{\circ}\text{C}$ .

## 12) QA/QC Requirements

12.1 This method shall operate under the formal Quality Assurance Program established at ALS and must maintain records that define the quality of data that is generated. Data shall be compared to established criteria in order to determine if the results of the analyses meet the performance characteristics of the method. It is required that an initial demonstration of capability and periodic analysis of laboratory reagent blanks, laboratory fortified blanks, and other QC solutions as a continuing check on performance. The accuracy and precision of the procedure must be validated *before* analyses of samples begin, or whenever significant changes to the procedures have been made.

12.2 A buffer check is analyzed after every 10 readings. For buffer checks, use either pH 4.00 or 10.00, choosing whichever standard brackets the majority of the previous samples with pH 7.00. The buffer check should be within 0.05 pH units of the true value.

12.3 A Laboratory Control Sample (LCS) is analyzed at a frequency of one per 20 samples. The LCS is a purchase reference material. The Certified Value and Acceptance Limits listed on the vendor's Certificate of Analysis are to be used to evaluate the LCS recovery. Analyze the LCS prior to the sample set. The LCS is prepared identically to associated samples and documented on the analytical. Worksheet If the LCS is outside of the acceptance limits, recalibrate the instrument.

12.4 For SM 4500 H+B-2011, a duplicate sample is analyzed at a frequency of 10% of the samples, with acceptance criteria of 10% RPD between the two readings.

12.5 For 9040C and 150.1, all samples must be analyzed in duplicate and give results of < 0.1 pH units between the two readings. If the duplicate is outside of this limit, the

	STANDARD OPERATING PROCEDURE	Water pH Determination
	ALS   Environmental - Kelso	GEN-pHW Rev. 17.0
		Effective: 2/18/2021
		SOP Review: 2/17/2021
		Page 7 of 8

sample is reanalyzed. Duplicates are documented on the benchsheet. If the duplicate is outside of these limits, the sample is reanalyzed. Duplicates are documented on the benchsheet. For duplicate analyses, calculate relative percent difference as follows:

$$RPD = \frac{S_1 - S_2}{Avg} * 100$$

Where S1 = Sample with higher value  
 S2 = Sample with lower value  
 Avg. = Average of the two sample values

### 13) Data Reduction and Reporting

#### 13.1 Data Review and Assessment

13.1.1 Following primary data interpretation and calculations, all data is reviewed by a secondary analyst. Following generation of the report, the report is also reviewed. Refer to the *SOP for Laboratory Data Review Process* (ADM-DREV) for details. The person responsible for final review of the data report and/or data package should assess the overall validity and quality of the results and provide any appropriate comments and information to the Project Manager for inclusion in the report narrative.

13.1.2 It is the analyst's responsibility to review analytical data to ensure that all quality control requirements have been met for each analytical run. Results for QC analyses are calculated and recorded as specified in this SOP. Average, RPD, spike level and spike recovery are entered on the analytical spreadsheet for corresponding samples. All data will be initialed, dated and attached to required data quality worksheet.

#### 13.2 Reporting

13.2.1 Refer to the *SOP for Data Reporting and Report Generation* (ADM-RG) for reporting guidelines

13.2.2 The analyst enters data directly into ALSLIMS templates. An Analytical Results Summary is generated for that analytical batch showing all QC and sample results. After primary and secondary review, final reports are generated in ALSLIMS by compiling the SMO login, sample prep database, instrument date, and client-specified report requirements (when specified). The forms generated may be ALS standard reports, DOD, or client-specific reports. The compiled data from LIMS is also used to create EDDs.

### 14) Method Performance

14.1 This method was validated through single laboratory studies of accuracy and precision. Refer to the reference method for additional method performance data available.

### 15) Pollution Prevention and Waste Management

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Water pH Determinaiton
	GEN-pHW Rev. 17.0
	Effective: 2/18/2021
	SOP Review: 2/17/2021
	Page 8 of 8

15.1 The laboratory will comply with all Federal, State and local regulations governing waste restrictions as specified in the ALS Lab Waste Management Plan.

## 16) Corrective Actions for Out-of-Control Data or Unacceptable Data

16.1 Refer to the SOP for *Nonconformance and Corrective Action Procedures* (ADM-NCAR) for procedures for corrective action.

16.2 Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

## 17) Training

17.1 All analysts performing this analysis are required to read and understand this SOP.

17.2 Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

17.3 It is required that an initial demonstration of capability and periodic analysis of laboratory reagent blanks, laboratory fortified blanks, and other QC solutions as a continuing check on performance.

	STANDARD OPERATING PROCEDURE	TOC, DOC, TIC, TC - Water
	ALS   Environmental - Kelso	Revision 15
		Effective: 1/07/2019
		Page 2 of 16

## 1) Scope & Applicability

- 1.1 This procedure is applicable to the determination of Total Organic Carbon (TOC) in drinking, surface and saline waters, domestic and industrial wastewater using methods EPA 9060A, EPA 415.1, and Standard Methods 5310C-2011. The procedure may also be extended to certain domestic or industrial wastes.
- 1.2 This procedure may be modified for quantification of Dissolved Organic Carbon (DOC) where
- 1.3 DOC is determined from a filtered sample.
- 1.4 Normal operating parameters (i.e. 1 ml sample loop) yield a Method Reporting Limit (MRL) of 0.5 mg/L C. A 5 ml sample loop may be used to lower the MRL to 0.1 mg/L C. The data quality objectives for target analytes in water are presented in Table 2 and in the ALS Kelso DQO Table.
- 1.5 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DOD ELAP. QC requirements defined in the SOP *Department of Defense Projects - Laboratory Practices and Project Management (ADM-DOD)* may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 Total Organic Carbon (TOC) is determined by measuring carbon dioxide released by chemical oxidation of the non-purgeable organic carbon in the sample. After the sample has been acidified and purged of inorganic carbon, sodium persulfate, a strong oxidizer, is added. This oxidant quickly reacts with non-purgeable organic carbon in the sample at 100°C to form carbon dioxide. When the reaction is complete, the carbon dioxide is purged from the solution, concentrated by trapping then thermally desorbed (200°C) and carried into a non-dispersive infrared detector that has been calibrated to directly display the mass of carbon dioxide detected. The resulting carbon mass in the form of carbon dioxide is the equivalent to the mass of organic carbon originally in the sample.
- 2.2 Total Inorganic Carbon is determined by carbon dioxide released by acidification of a sample. The pH of the sample is lowered; the carbonate and bicarbonate ions are then converted to carbon dioxide. This carbon dioxide is purged from the solution, concentrated by trapping, and detected as described for TOC.

## 3) Definitions

- 3.1 Batch - A batch of samples is a group of environmental samples that are prepared and/or analyzed together as a unit with the same process and personnel using the same lot(s) of reagents. It is the basic unit for analytical quality control.
  - 3.1.1 Preparation Batch - A preparation batch is composed of one to twenty field samples, all of the same matrix, and with a maximum time between the start

STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

TOC, DOC, TIC, TC - Water

Revision 15

Effective: 1/07/2019

Page 3 of 16

of processing of the first and last samples in the batch to be 24 hours.

3.1.2 Analysis Batch - Samples are analyzed in a set referred to as an analysis sequence. The sequence begins with instrument calibration (initial or continuing verification) followed by sample extracts interspersed with calibration standards (CCBs, CCVs, etc.) The sequence ends when the set of samples has been injected or when qualitative and/or quantitative QC criteria indicate an out-of-control situation.

3.2 Sample

3.2.1 Field Sample - An environmental sample collected and delivered to the laboratory for analysis; a.k.a., client's sample.

3.2.2 Laboratory Sample - A representative portion, aliquot, or subsample of a field sample upon which laboratory analyses are made and results generated.

3.3 Quality System Matrix - The *matrix* of an environmental sample is distinguished by its physical and/or chemical state and by the program for which the results are intended. The following sections describe the matrix distinctions. These matrices shall be used for purpose of batch and quality control requirements.

3.3.1 Aqueous - Any groundwater sample, surface water sample, effluent sample, and TCLP or other extract. Specifically excluded are samples of the drinking water matrix and the saline/estuarine water matrix.

3.3.2 Drinking water - Any aqueous sample that has been designated a potable or potential potable water source.

3.3.3 Saline/Estuarine water - Any aqueous sample from an ocean or estuary or other salt-water source.

3.4 Method Blank (MB) - a solution of the laboratory prepared deionized water that is carried through analysis like a sample, to serve as a measure of contamination associated with laboratory storage, preparation, or instrumentation.

3.5 Filtration Blank - The filtration blank is an artificial sample composed of analyte-free water and is designed to monitor the introduction of artifacts into the filtration process. The filtration blank is carried through the entire filtration procedure.

3.6 Laboratory Control Samples (LCS) - The LCS is an aliquot of analyte free water or analyte free solid to which known amounts target analytes are added. The LCS is prepared and analyzed in exactly the same manner as the samples. The percent recovery is compared to established limits and assists in determining whether the batch is in control.

3.7 Sample Duplicate - a second aliquot of a sample that is treated exactly the same throughout laboratory analytical procedures. The purpose is to verify the precision associated with the laboratory procedures. Matrix Spike - aliquots of sample to which known amounts of an analyte of interest has been added. These are treated exactly the same throughout laboratory analytical procedures. The purpose of a matrix spike is to determine whether the sample matrix contributes bias to the analytical results.

## STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

TOC, DOC, TIC, TC - Water

Revision 15

Effective: 1/07/2019

Page 4 of 16

- 3.8 Calibration Standards - a solution of analytes prepared in the laboratory from stock standard solutions, diluted as needed, and used to calibrate the instrument response with respect to analytical concentration.
- 3.9 Independent Verification Standard (ICV) - A mid-level standard injected into the instrument after the calibration curve and prepared from a different source than the initial calibration standards. This is used to verify the validity of the initial calibration standards. The LCS when prepared from a different source will also serve as the ICV.
- 3.10 Laboratory Control Standards (LCS) - a solution of analytes prepared in the laboratory from stock standard solutions purchased or prepared independently from calibration standards.
- 3.11 Continuing calibration blank (CCB) - a blank solution of deionized water. CCB's are analyzed to verify that the instrument has not become contaminated during the course of the analytical run.
- 3.12 Continuing calibration verification standard (CCV) - a solution of prepared in the laboratory at approximately the midpoint of calibration curves. CCV's are analyzed to verify that the instrument performance has not changed during the course of the analytical run.
- 3.13 Rinse Blank (RB) - a solution of the laboratory prepared deionized water that is carried through analysis like a sample, to serve as a measure of carry-over from the previous sampling and analytical run.

#### 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. The department supervisor/manager or designee performs final review and sign-off of the data.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training. Documenting method proficiency is also the responsibility of the department supervisor/manager or designee.

#### 5) Interferences

- 5.1 Carbonate and bicarbonate carbon are interferences under the terms of this test and must be removed or accounted for in the final calculations
- 5.2 This procedure is applicable only to homogenous samples that can be injected reproducibly by microliter type syringe or pipette. The opening of the syringe or pipette limits the size of particles which may be included in the samples. The Teledyne TOC Fusion™ analyzer can analyze samples with suspended solids up to 500 microns diameter.
- 5.3 Positive bias may be caused by contaminants in the gas, dilution water, reagents, glassware, or other sample processing hardware. The use of high purity reagents and gases help minimize interference problems. Materials may be demonstrated to be free from interference by running reagent blanks
- 5.4 Interference by non-CO<sub>2</sub> gases: The infrared detector is sensitized to carbon dioxide and accomplishes virtually complete rejection of response from other gases which absorb energy in the infrared region. Trapping and desorption of carbon dioxide on

## STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

Revision 15

Effective: 1/07/2019

Page 5 of 16

the molecular sieve trap isolates the component of interest and allows the complete absence of interference in the system from gases other than carbon dioxide.

### 6) Safety

- 6.1 All appropriate safety precautions for handling solvents, reagents and samples must be taken when performing this procedure. This includes the use of personal protective equipment, such as, safety glasses, lab coat and the correct gloves.
- 6.2 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.
- 6.3 Sodium Persulfate is a strong oxidizer and should be handled with extreme care.
- 6.4 Phosphoric Acid is a corrosive material should be handled with extreme care.
- 6.5 Potassium Biphthalate and Sodium Carbonate are chemical irritants and may cause eye burns.

### 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 For most accurate analyses, sampling containers should be free of organic contaminants.
- 7.2 Sampling and storage of samples in glass bottles is preferable. If this is not feasible, sampling and storage in plastic bottles such as conventional polyethylene and cubitainers is permissible if it is established that the containers do not contribute contaminating organics to the samples.
  - 7.2.1 **Note:** A brief study performed at the EPA Laboratory indicated that distilled water stored in new, one quart cubitainers did not show any increase in organic carbon after two weeks exposure.
- 7.3 For samples requiring very low-level TOC analysis (below about 500 ppb C) attention to limiting contamination may be required. If possible, rinse bottles with sample before filling and carry field blanks through sampling procedure to check for any contamination that may occur. Collect and store samples in glass bottles protected from sunlight and seal with TFE-backed septa. Use certified clean sample vials for sampling and analysis. However if certified clean containers are not available or are found to be cleaned insufficiently further cleaning may be required. If necessary before use, wash bottles with acid, seal with Aluminum foil, and bake at 400°C for at least one hour. Wash un-cleaned TFE septa with detergent, rinse repeatedly with organic free water, and wrap in aluminum foil and bake at 100°C for one hour. Check performance of new or cleaned septa by running appropriate blanks. Preferably use thick silicone rubber-backed TFE septa with open ring caps to produce a positive seal. Less rigorous cleaning may be acceptable if the concentration range is relatively high. Check bottle blanks to determine effectiveness or necessity of cleaning.

## STANDARD OPERATING PROCEDURE

ALS | Environmental - Kelso

TOC, DOC, TIC, TC - Water

Revision 15

Effective: 1/07/2019

Page 6 of 16

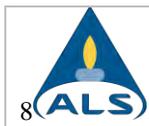

- 7.4 Because of the possibility of oxidation or bacterial decomposition of certain components in aqueous samples, the time between sample collection and analysis should be minimized. In addition, the samples should be kept cool (4°C) and protected from sunlight and atmospheric oxygen.
- 7.5 In situations where analysis cannot be performed within two hours (2 hours) of sampling, the sample must be acidified (pH < 2) with Phosphoric or Sulfuric acid. Once preserved, samples must be analyzed within 28 days. Note that acid preservation invalidates any inorganic carbon determination on the samples.
- 7.6 Samples requiring DOC analyses should be filtered through a prewashed 0.45 micron glass microfiber membrane filter prior to acid preservation. A DI water filter blank should also be included with the filtration batch to determine potential for sample contamination from filter or filtration apparatus.

### 8) Apparatus and Equipment

- 8.1 TOC analyzer: Teledyne -Tekmar, Model TOC Fusion, S/N: US10165001.
- 8.2 Whatman 0.45µm glass microfiber membrane filter, or equivalent.

### 9) Standards, Reagents, and Consumable Materials

- 9.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Standards, reagents and consumable material documentation shall indicate traceability to purchased reagents or compounds. Refer to the SOP *Reagent/Standards Login and Tracking* (ADM-RTL) for the complete procedure and documentation requirements.
- 9.2 All stocks, working solutions and sample dilutions should be prepared using deionized water (DI) conforming to ASTM Type I or ASTM Type II reagent water. For more information on reagent water generation, refer to the related SOP, Operation and Maintenance of Laboratory Reagent Water Systems.
- 9.3 Potassium Biphthalate (KHP) stock solutions:
- 9.3.1 1000 ppm C stock solution is prepared by adding 2.128 g of KHP (previously dried to a constant weight at 105°C) into a 1000 ml volumetric flask. Dilute to volume with reagent water. Solution contains 1.0 ug C per ul.
- 9.3.2 5000 ppm C stock solution is prepared by adding 10.64 g of KHP (previously dried to a constant weight at 105°C) into a 1000 ml volumetric flask. Dilute to volume with reagent water. Solution contains 5.0 ug C per ul.
- Note:** Stock solution has a shelf life of six months after preparation. Sodium oxalate and acetic acid are not recommended as stock solutions.
- 9.3.3 Calibration standards used are 5 ppm and 50 ppm. The instrument is configured to make Standard dilutions.
- 9.3.4 Sodium Carbonate Stock solution (1000 ppm C) - Prepare stock solution by adding 8.826 g of Na<sub>2</sub>CO<sub>3</sub> (previously dried to a constant mass at 105°C) to a

## STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

TOC, DOC, TIC, TC - Water

Revision 15

Effective: 1/07/2019

Page 7 of 16

1000 ml volumetric flask. Dilute to volume with reagent water. Solution contains 1.0 ug C per ul.

- 9.3.5 Sodium Persulfate - Prepare solution of sodium persulfate by dissolving 100g  $\text{Na}_2\text{S}_2\text{O}_8$  into (852 mL DI  $\text{H}_2\text{O}$  plus 36 mL  $\text{H}_3\text{PO}_4$ ), then purge with  $\text{N}_2$  for 30 minutes before use. Reagent has a shelf life of one month.
- 9.3.6 Phosphoric Acid (21%) - Prepare 21% by volume solution of phosphoric acid by adding 150 mL of ACS reagent grade 85%  $\text{H}_3\text{PO}_4$  to 450 mL reagent water. Reagent has a shelf life of one month.
- 9.3.7 Continuing Calibration Verification (CCV) - The CCV is prepared by diluting 10.0 mLs of 5000 ppm TOC stock solution 1000 mLs of deionized water in a Class "A" volumetric flask. Resulting concentration is 50.0 ppm. The instrument runs the CCV check standard at a 1:2 dilution (25 ppm).
- 9.3.8 Laboratory Control Sample (LCS) - The LCS is prepared from an ERA QC - Plus Demand solution. The true value is determined based on the lot number of the standard.
- 9.3.9 Gas Service: Nitrogen.

## 10) Preventive Maintenance

### 10.1 Daily Maintenance Checks

- 10.1.1 Verify the gas source is supplying an input pressure of 50 psi.
- 10.1.2 Verify that there is ample persulfate available for sample analysis. Verify that the persulfate has not expired.
- 10.1.3 Verify that there is ample acid available for sample analysis. Verify that the acid has not expired. Make sure the DI water supply is sufficient for sample analysis.
- 10.1.4 After the UV lamp has warmed up for 15 minutes, verify that the detector baseline is within the range of 0-5 Absorbance units (Abs). Perform the Detector Offset function if necessary.
- 10.1.5 Verify that the waste container has sufficient volume to contain the waste generated.

### 10.2 Weekly Maintenance Checks

- 10.2.1 Check the copper side of the halogen scrubber. When copper is discolored completely, replace both the copper and tin in the scrubber.
- 10.2.1 Make sure the two screws that attach the 7-port Valve to the Syringe Pumper are tight.

### 10.3 Monthly Maintenance Checks

- 10.3.1 Inspect and clean the reactor and sparger if necessary.
- 10.3.2 Flush sample transfer line with generous amounts of DI water. Inspect the

## STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

TOC, DOC, TIC, TC - Water

Revision 15

Effective: 1/07/2019

Page 8 of 16

permeation dryer for damage and water accumulation.

### 10.4 Semi-Annually Maintenance Checks

10.4.1 Replace the O-rings in the UV reactor vessel.

10.5 For additional information refer to the Fusion™ Preventative Maintenance section of the User Manual, Page 8-2.

## 11) Procedure

### 11.1 TOC analyzer: Teledyne -Tekmar, Model TOC Fusion - Preparation and Analysis

11.1.1 Perform the required daily maintenance checks.

11.1.2 If the TOC TekLink™ software is not already in operation, launch the TOC TekLink™ software.

11.1.3 Login with the User Name: (Fusion 1) and Password: (Fusion1), and connect into the Fusion program.

11.1.4 Open the daily startup schedule, save the schedule to reflect the current date (m/d/y/, make any necessary adjustments, and click “Ready”.

- TOC/DOC daily startup schedule: CAS\_SALT\_010711.
- Extended Reaction (for salt water) daily startup schedule, Extended Reaction 021711.
- TIC/DIC daily startup schedule: IC 030411.
- TOC Low Level daily startup schedule: CAS\_High\_Sensitivity.

11.1.5 After the UV lamp has warmed up for 15 minutes, verify that the detector baseline is within the range of the 0-5 Absorbance units (Abs). Perform the Detector Offset function if necessary.

*Note: If the instrument is allowed to sit idle for 20 minutes, it will automatically switch to standby mode.*

11.1.6 Click the start button to start the sequence.

11.1.7 The schedule should contain three Cleans, one Reagent/Acid Blank, and one rinse blank before the first CCV.

11.1.8 Scan the samples barcode into the Run Sequence and load the samples into the carousel. Ensure that the sample’s position on the schedule matches the number on the carousel.

11.1.9 An initial CCV is run after the Rinse Blank and must be analyzed following every tenth injection and at the end of the run. The CCV is a 25.0 ppm TOC Standard made from stock KHP solution. Recovery must be **90–110%** of the value (**91–106% for Arizona** samples). For low level analyses (i.e. 0.1 ppm MRL), the CCV is a 5.0 ppm standard. Calculate the CCV recovery as follows:

	STANDARD OPERATING PROCEDURE	TOC, DOC, TIC, TC - Water
	ALS   Environmental - Kelso	Revision 15
		Effective: 1/07/2019
		Page 9 of 16

$$\%R = X/TV \times 100$$

Where X = Measured concentration of the CCV  
TV = True value of CCV

- 11.1.10 A Continuing Calibration Blanks (CCB) must be analyzed every 10 injections. CCB measured concentrations must be less than the MRL.
- 11.1.11 Sample Analysis
  - 11.1.11.1 Once the UV lamp has warmed up for 15 minutes, and the detector baseline is within the range of 0.5 Absorbance units (Abs), the instrument is ready for analysis.
  - 11.1.11.2 Load samples vials into the autosampler carousel according to the analytical run sequence shown below. Thoroughly shake TOC samples before loading. Click the start button on the schedule to begin analysis.
- 11.1.12 When performing method 5310C and EPA 415.1, analyze all environmental samples in duplicate. .
- 11.1.13 When performing method 9060A, analyze all samples in quadruplicate.

## 12) Quality Assurance/Quality Control Requirements

### 12.1 Initial Precision and Recovery Validation

- 12.1.1 The ability of each analyst/instrument to generate acceptable accuracy and precision must be validated and documented before analysis of samples begins, or whenever significant changes to the procedures have been made. To do this, four water samples are spiked with the LCS spike solution, then prepared and analyzed. Method criteria must be met for these results.

### 12.2 Method Detection Limits and Method Reporting Limits

- 12.2.1 A method detection limit (MDL) study must be undertaken before analysis of samples can begin. To establish detection limits that are precise and accurate, the analyst must perform the following procedure. Spike seven blank matrix (water or soil) samples with MDL spiking solution at a level below the MRL. Follow the analysis procedures to analyze the samples.
- 12.2.2 Calculate the average concentration found (x) in µg/mL, and the standard deviation of the concentrations (s) in µg/mL for each analyte. Calculate the MDL for each analyte. Refer to the ALS SOP *Performing Method Detection Limit Studies and Establishing Limits of Detection and Quantification (CE-QA011)*. The MDL study must be verified annually.

	STANDARD OPERATING PROCEDURE	TOC, DOC, TIC, TC - Water
	ALS   Environmental - Kelso	Revision 15
		Effective: 1/07/2019
		Page 10 of 16

### 12.3 Limits of Quantification (LOQ)

12.3.1 The laboratory must establish a LOQ for each analyte as the lowest reliable laboratory reporting concentration or in most cases the lowest point in the calibration curve which is less than or equal to the desired regulatory action levels, based on the stated project requirements. Analysis of a standard or extract prepared at the lowest point calibration standard provides confirmation of the established sensitivity of the method. Refer to the ALS SOP *Performing Method Detection Limit Studies and Establishing Limits of Detection and Quantification* (CE-QA011).

12.3.2 The Method Reporting Limits (MRLs) used at ALS are the routinely reported lower limits of quantitation which take into account day-to-day fluctuations in instrument sensitivity as well as other factors. These MRLs are the levels to which ALS routinely reports results in order to minimize false positive or false negative results. The MRL is normally two to ten times the method detection limit.

12.4 Ongoing QC Samples each sample batch (20 or fewer samples) required are described in the ALS-Kelso Quality Assurance Manual and in the SOP for Sample Batches. Additional QC Samples may be required in project specific quality assurance plans (QAPP). General QC Samples are:

#### 12.4.1 Method Blank (MB)

12.4.1.1 A method blank is extracted and analyzed daily with every batch of 20 (or fewer) samples to demonstrate that there are no method interferences. If the method blank shows any hits above the reporting limit, corrective action must be taken. Corrective action includes recalculation, reanalysis, system cleaning, or re-extraction and reanalysis. For some project specific needs, exceptions may be noted and method blank results above the MRL may be reported for common lab contaminants.

#### 12.4.2 Laboratory Control Sample (LCS)

12.4.2.1 A Laboratory Control Sample (LCS) for SM 5310C and EPA 415.1 must be analyzed with each batch of 20 or fewer samples. The LCS is prepared from a standard which is an independent source from the calibration standards. Acceptance criteria are given in Table 2. This statistically derived acceptance limit is subject to change as limits are updated.

12.4.2.2 When performing Method 9060 analysis, the second source LCS must be analyzed every 15 samples rather than every 20 samples.

12.4.2.3 Calculate the LCS recovery as follows:

$$\%R = X/TV \times 100$$

Where X = Concentration of the analyte recovered  
TV = True value of amount spiked

	STANDARD OPERATING PROCEDURE	TOC, DOC, TIC, TC - Water
	ALS   Environmental - Kelso	Revision 15
		Effective: 1/07/2019
		Page 11 of 16

12.4.3 Sample Duplicates (DUP)

12.4.3.1 A sample duplicate or matrix spike duplicate (MSD) must be analyzed with every analytical batch.

12.4.3.2 Calculate Relative Percent Difference (RPD) as:

$$\%RPD = \frac{|R1 - R2|}{(R1 + R2) / 2} \times 100 \quad \text{Where R = Result}$$

12.4.3.3 The RPD is calculated as follows:

$$\frac{Hi - Lo}{Avg.} \times 100$$

12.4.4 The percent RPD for EPA 9060A and EPA 415.1 must be  $\leq 20\%$ . This statistically derived acceptance limit is subject to change as limits are updated. For SM 5310C, all duplicates must be within **10%** RPD.

Relative Percent Difference calculation:

$$\%RPD = \frac{(S - D)}{((S + D)/2)}$$

where: S = Initial sample result  
D = Duplicate sample result

12.4.5 Matrix Spikes

12.4.5.1 For SM 5310C and EPA 415.1, analyze one matrix spike sample (MS) for every analytical batch of twenty samples.

12.4.5.2 Method 9060A analyze one matrix spike sample (MS) for every analytical batch of ten samples.

12.4.5.3 Spike 50 ul of 5000 ppm KHP stock solution to 10.0 mLs of sample. For low level analysis, spike 50 ul of 1000 ppm KHP stock solution to 10.0 mLs of sample. Acceptance criteria are given in Table 2. This statistically derived acceptance limit is subject to change as limits are updated.

Calculate percent recovery as follows:

$$Matrix\ Spike\ Recovery = \frac{Spiked\ Sample - Sample}{Spike\ Added} \times 100$$

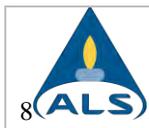

13) Data Reduction and Reporting (or Documentation and Records)

	STANDARD OPERATING PROCEDURE	TOC, DOC, TIC, TC - Water
	ALS   Environmental - Kelso	Revision 15
		Effective: 1/07/2019
		Page 12 of 16

- 13.1 Refer to the SOP for Data Reporting and Report Generation for reporting guidelines.
- 13.2 Preliminary results are reviewed to determine if dilutions are required. Sample information is transferred to an [REDACTED] spreadsheet for calculations (see R:\WET\ANALYSES\TOC\DATA). Instrument baseline is determined by taking the average of all Method Blanks, CCB's, (see R:\WET\ANALYSES\TOC\TOC\_CBA1.SPD ). Sample concentration is corrected by subtracting calculated blank average (CBA) from instrument response. Concentration and sample identification number are highlighted for reporting purposes.
- 13.3 For 5310C, report the result from a single analysis. For 9060A, report both the average and the range from the quadruplicate analyses.
- 13.4 It is the operators' responsibility to review analytical data to ensure that all quality control requirements have been met for each analytical run. Results for QC analyses are calculated and recorded as specified in procedures section of the SOP. Average, RPD, spike level and spike recovery are entered on spreadsheet (see append. B) for corresponding samples. All data will be initialed, dated and attached to required data quality worksheet.
- 13.5 Reports are generated in the ALS LIMS by compiling the SMO login, sample prep database, instrument date, and client-specified report requirements (when specified). This compilation is then transferred to a file which [REDACTED] uses to generate a report. The forms generated may be ALS standard reports, DOD, or client-specific reports. The compiled data from LIMS is also used to create EDDs.
- 13.6 As an alternative, reports are generated using [REDACTED] templates located in R:\WET\FORMS. The analyst should choose the appropriate form and QC pages to correspond to required tier level and deliverables requirements. The results are then transferred, by hand or electronically, to the templates the saved to R:\WET\WIP.
- 13.7 Data Review and Assessment
- 13.7.1 Following primary data interpretation and calculations, all data is reviewed by a secondary analyst. Following generation of the report, the report is also reviewed. Refer to the *SOP for Laboratory Data Review Process* for details. The person responsible for final review of the data report and/or data package should assess the overall validity and quality of the results and provide any appropriate comments and information to the Project Chemist to inclusion in the report narrative.

## 14) Method Performance

- 14.1 The accuracy and precision of the procedure must be validated before analysis of samples begins, or whenever significant changes to the procedures have been made. To do this, four LCS aliquots are prepared and analyzed. The average percent recovery must meet the laboratory control sample acceptance limits.
- 14.2 The method detection limit (MDL) is established using the procedure described in the SOP CE-QA011, *Performing Method Detection Limit Studies and Establishing Limits of*

*Detection and Quantification.* Method Reporting Limits are established for this method based on MDL studies and as specified in the ALS Quality Assurance Manual.

## 15) Pollution Prevention and Waste Management

- 15.1 It is the laboratory's practice to minimize the amount of solvents, acids and reagent used to perform this method wherever feasible. Standards are prepared in volumes consistent with methodology and only the amount needed for routine laboratory use is kept on site. The threat to the environment from solvent and reagents used in this method can be minimized when recycled or disposed of properly.
- 15.2 The laboratory will comply with all Federal, State and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.

## 16) Corrective Actions for Out-of-Control Data or Unacceptable Data

- 16.1 Refer to the SOP for *Non Conformance and Corrective Action* (CE-QA008) for procedures for corrective action. Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.
- 16.2 Handling out-of-control or unacceptable data
- 16.2.1 On-the-spot corrective actions that are routinely made by analysts and result in acceptable analyses should be documented as normal operating procedures, and no specific documentation need be made other than notations in laboratory maintenance logbooks, run logs, for example.
- 16.2.2 Some examples when documentation of a nonconformity is required using a Nonconformity and Corrective Action Report (NCAR):
- Quality control results outside acceptance limits for accuracy and precision.
  - Method blanks or continuing calibration blanks (CCBs) with target analytes above acceptable levels.
  - Sample holding time missed due to laboratory error or operations.
  - Deviations from SOPs or project requirements.
  - Laboratory analysis errors impacting sample or QC results.
  - Miscellaneous laboratory errors (spilled sample, incorrect spiking, etc.).
  - Sample preservation or handling discrepancies due to laboratory or operations error.
  - Customer inquiries concerning data quality or services (when applicable). NCAR not required for simple corrections with no impact to the client.
  - Data errors reported to clients, non-conforming re-checks.
  - Deficiencies found during internal or external audits.
  - Login errors or shipping errors.
  - IT issues if there is a significant impact to a client.
  - Turnaround time complaints.

## 17) Training

## STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

TOC, DOC, TIC, TC - Water

Revision 15

Effective: 1/07/2019

Page 14 of 16

- 17.1 Review literature Review this SOP. Also review the applicable SDS for all reagents and standards used. Following these reviews, observe the procedure performed by an experienced analyst.
- 17.2 The next training step is to assist in the procedure under the guidance of an experienced analyst. During this period, the analyst is expected to transition from a role of assisting, to performing the procedure with minimal oversight from an experienced analyst.
- 17.3 Perform initial precision and recovery (IPR) study as described above for water samples. Summaries of the IPR are reviewed and signed by the supervisor. Copies may be forwarded to the employee's training file. For applicable tests, IPR studies should be performed in order to be equivalent to NELAC's Initial Demonstration of Capability.
- 17.4 Training is documented following the *ALS-Kelso Training Procedure* (ADM-TRAIN). When the analyst training is documented by the supervisor on internal training documentation forms, the supervisor acknowledges that the analyst has read and understands this SOP and that adequate training has been given to the analyst to competently perform the analysis independently.

### 18) Method Modifications

- 18.1 There are no known modifications in this laboratory standard operating procedure from the reference method.

### 19) Summary of Changes

- 19.1 Reformatted SOP to current ALS format.
- 19.2 Updated safety references and definitions.
- 19.3 Miscellaneous format revisions and typographical/grammatical corrections.
- 19.4 Section 8: Model 1010 Total Organic Carbon Analyzer: removed from the equipment list and when referenced in the SOP.  
TOC analyzer: Teledyne -Tekmar, Model TOC Fusion, - was added into numerous sections throughout the SOP.
- 19.5 Section 9: Updated calibration standards; sodium persulfate preparation; removed the ICV from the analysis.
- 19.6 Section 11: Numerous edits throughout the section.
- 19.7 Added EPA 415.1 into the SOP, which had previously been previously removed.

		Suspended Solids Determination
	STANDARD OPERATING PROCEDURE	GEN-TSS Rev. 14.0
	ALS   Environmental - Kelso	Effective: 6/10/2019
		SOP Review: 2/18/2021
		Page 2 of 9

## 1) Scope & Applicability

- 1.1 This procedure is used to determine suspended solids using 2540 D-2011. The procedure tests for material in a well-mixed sample that is filtered through a glass fiber filter and is retained on the filter and dried to a constant weight at 103-105°C.
- 1.2 This method is applicable to drinking, surface, and saline waters, domestic and industrial wastes.
- 1.3 Using 200 mL of sample, the practical range of determination is 5 mg/L to 20,000 mg/L. using 500 mL of sample, the range of determination is expanded down to 2 mg/L.
- 1.4 The Method Detection Limit (MDL) is a function of the sample volume used and range of the balance. The MDL is 5 mg/L using 200 mL of sample. Using 500 mL of sample, the MDL is 2 mg/L.
- 1.5 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DOD ELAP. QC requirements defined in the SOP *Department of Defense Projects - Laboratory Practices and Project Management*, may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 A well-mixed sample is filtered through a SSI Accudisk™ 1.5 µm binderless, borosilicate glass fiber filter, pre-washed, prepared and pre-weighed by the manufacturer, (in accordance with SM 2540D), and the residue retained on the filter is dried to a constant weight at 103-105°C. The increased weight of the filter represents the total suspended solids.
- 2.2 The alternative procedure uses glass fiber filter discs, 42.5 mm, Whatman GF/C or equivalent,
- 2.3 When pre-washed, prepared and pre-weighed filters are not in use. Refer to the procedure on the preparation of glass-fiber filter disks..

## 3) Definitions

- 3.1 For laboratory definitions applicable to most analyses, refer to the SOP for [Sample Batches](#).

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. The department supervisor/manager or designee performs final review and sign-off of the data.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst

		Suspended Solids Determination
	STANDARD OPERATING PROCEDURE	GEN-TSS Rev. 14.0
	ALS   Environmental - Kelso	Effective: 6/10/2019
		SOP Review: 2/18/2021
		Page 3 of 9

training and method proficiency as referenced in *Employee Training and Orientation*, ADM-TRAIN.

## 5) Interferences

- 5.1 Non-representative particulates such as leaves, sticks, fish and lumps of fecal matter should be excluded if it is determined that their inclusion is not desired in the final result.
- 5.2 Excessive residue on the filter may form a water-entrapping crust. Limit the sample size to that yielding no more than 200 mg residue.
- 5.3 For samples high in total dissolved solids, thoroughly wash the filter to ensure removal of dissolved material.
- 5.4 Prolonged filtration times resulting from filter clogging may produce high results because of increased colloidal materials captured on the clogged filter.
- 5.5 Filtration apparatus, filter material, pre-washing, post-washing, and drying temperature are specified because they can affect the results.

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Samples should be collected in pre-cleaned plastic sample bottles and must be iced or refrigerated at 0-6°C from time of collection until preparation or analysis.
- 7.2 Water samples must be analyzed within 7 days of sampling.

## 8) Apparatus and Equipment

- 8.1 SSI Accudisk™ (Part No. 425TSS-AD) 1.5 µm binderless, borosilicate glass fiber filter, pre-washed, prepared and weighed by the manufacturer, in accordance with SM 2540D for use in determining Total Suspended Solids (TSS).
- 8.2 Magnetic Filtration Apparatus.
- 8.3 Suction Flask, 1 Liter.
- 8.4 Drying Oven.
- 8.5 Desiccator.
- 8.6 Forceps.
- 8.7 Graduated Cylinder.
- 8.8 Analytical Balance, capable of weighing to 0.1 mg.
- 8.9 Balance calibration verification weights, ASTM Class 1 (or equivalent): 0.01 g, 1 g, 10 g, and 100 g.

		Suspended Solids Determination
	STANDARD OPERATING PROCEDURE	GEN-TSS Rev. 14.0
	ALS   Environmental - Kelso	Effective: 6/10/2019
		SOP Review: 2/18/2021
		Page 4 of 9

8.10 Alternative Procedure: Glass fiber filter discs, 42.5 mm, Whatman GF/C or equivalent may be used when pre-washed and pre-weighed filters are not in use.

## 9) Standards, Reagents, and Consumable Materials

### 9.1 Reagents

9.1.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Refer to the SOP *Reagent/Standards Login and Tracking* (ADM-RLT) for the complete procedure and documentation requirements.

9.1.2 All stocks, working solutions and sample dilutions should be prepared using deionized water (DI) conforming to ASTM Type I or ASTM Type II reagent water. For more information on reagent water generation, refer to the related SOP, Operation and Maintenance of Laboratory Reagent Water Systems.

### 9.2 Standards

9.2.1 Stock standard solutions may be purchased from a number of vendors. All standards purchased from vendors must be traceable to NIST or A2LA certified reference materials. Purchased standards are prepared in DI water. The vendor-assigned expiration date is used.

9.2.2 Laboratory Control Sample (LCS) – Prepared from ERA, QC Plus-solids, and Catalog No. 4033.

9.2.2.1 The LCS is prepared by transferring a container of QC Plus – Solids, to 1000 mL volumetric flask. This is done by wetting the contents of the vial with about 2 mL of DI water and transferring the wetted solids standard to a 1000 mL volumetric flask to which 100 – 200 mL of DI water has been previously added. Rinse the standards container 3 times with DI water to ensure all contents are transferred to the volumetric flask. Bring up to 1000 mL in the volumetric flask with DI water.

9.2.2.2 Document the preparation of the LCS solution in a reagent log book. The true value or concentration is calculated from the standards certificate of analysis. This standard is good for 7 days and is stored at 0-6°C.

## 10) Preventive Maintenance

10.1 Multi-point balance calibration verifications are required for each day the balance is used. The NELAC Quality System Standards and DoD Quality System Manual require that the balance verifications be performed prior to use on each day of use. The

		Suspended Solids Determination
	STANDARD OPERATING PROCEDURE	GEN-TSS Rev. 14.0
	ALS   Environmental - Kelso	Effective: 6/10/2019
		SOP Review: 2/18/2021
		Page 5 of 9

calibration verification weights must bracket the range of use. For additional information, refer to the SOP *Documenting Laboratory Balance and Temperature Checks* (ADM-BAL).

- 10.2 A bound logbook is used to record all balance measurements. Format the logbook such that the date, initials, balance I.D., weight set ID, measurements, and specifications for the check weights are listed for each balance. Record each calibration verification measurement in the logbook. Entries into logbooks are to be performed in accordance with the SOP for *Making Entries Onto Analytical Records*.
- 10.3 The laboratory utilizes an external calibration service that is ISO 17025 accredited to perform primary calibration and re-certification of ovens housing an internal temperature recorder/display as part of its operational system. A copy of the external calibration service's scope of accreditation is on file in the QA department. For support equipment calibration and/or re-certification frequency, refer to the SOP *Support Equipment Monitoring and Calibration* (ADM-SEMC).

## 11) Procedure

- 11.1 Selections of sample volume - For clean samples, choose a sample volume of 200 mL. If during filtration of the initial volume, the filtration rate drops rapidly, or if filtration time exceeds 5 to 10 minutes, the sample volume should be decreased. A smaller sample volume may be used initially if it is apparently visible that the TSS concentration will be high. For samples associated with Wisconsin DNR regulations, a 500 mL sample must be used.

**Note:** Although very unusual, if a small volume is used that requires sample transfer by other means than a graduated cylinder, use a pipette. In this case, if suspended solids are present use a wide-bore pipette.

- 11.1.1 If pre-washed, dried and pre-weighed Accudisk™ filters are used, the filter weights may be scanned into the TSS benchsheet using the hand-held scanner.
- 11.1.2 The Accudisk™ filters are supplied in individual aluminum pans labeled with the weight of the filter. Scan the barcode on the side of the individual aluminum pan. The computer will record the individual pan number and the initial filter weight in the appropriate highlighted ██████ cell for the scanned information, and will populate cells for individual pan numbers and initial filter weights.
- 11.2 Assemble the filtering apparatus and begin suction. Wet the filter with a small volume of distilled water to seat it to fritted support.
- 11.3 Shake the sample vigorously and transfer the pre-determined sample volume selected to the filter using a graduated cylinder.
- 11.4 Filter the sample through the Accudisk™ filter (or by means of the alternative filtration method as described).
- 11.5 With suction on, wash the graduated cylinder, filter, non-filterable residue and filter funnel wall with three portions of distilled water allowing complete drainage between

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Suspended Solids Determination
	GEN-TSS Rev. 14.0
	Effective: 6/10/2019
	SOP Review: 2/18/2021
	Page 6 of 9

washing. Remove all traces of water by continuing to apply vacuum after water has passed through.

**Note:** Total volume of wash water used should equal approximately 30 mL.

- 11.6 Carefully remove the filter from the filter support. Dry overnight at 103-105°C. Cool in a desiccator and weigh.
- 11.7 Return the filters to the oven and dry at least one hour at 103-105°C. Cool in a desiccator and weigh. The weight must agree with the first weight, within 0.5 mg. Repeat cycle of drying, cooling, desiccating and weighing until the weight change is within 0.5 mg.
- 11.8 Instructions for 24 hour rush samples:
  - 11.8.1 Dry at least one hour at 103-105°C. Samples high in suspended solids may need a longer drying period.
  - 11.8.2 Cool in desiccator and weigh.
  - 11.8.3 Repeat cycle of drying, cooling, desiccating and weighing until the weight change is within 0.5 mg.
- 11.9 Record the balance I.D. used for all weightings on the bench sheet.
- 11.10 Alternative procedure when pre-washed and weighted filters are not in use.
- 11.11 Preparation of glass fiber filter disc - Place the disc on membrane filter apparatus. While vacuum is on, wash the disc with three successive 20 mL volumes of distilled water. Remove all traces of water by continuing to apply vacuum after water has passed through. Discard washings. Remove filter from the apparatus and place in a petri dish. Dry the filters in an oven at 103-105°C for one hour. Remove to a desiccator and cool for at least 30 minutes. Weigh immediately before use. Note: The filter should be handled with forceps at all times.

## 12) QA/QC Requirements

- 12.1 Ongoing QC Samples required are described in the ALS-Kelso Quality Assurance Manual and in the SOP for *Sample Batches* (ADM-BATCH). Additional QC Samples may be required in project specific quality assurance plans (QAPP). For example projects managed under the DOD ELAP must follow requirements defined in the DoD *Quality Systems Manual for Environmental Laboratories*. General QA requirements for DoD QSM are defined in the laboratory SOP, *Department of Defense Projects - Laboratory Practices and Project Management*. General QC requirements are:
  - 12.1.1 Prior to, and after each analysis batch, balance calibration verification (CCV) is performed using weights bracketing the sample weights. A system of documentation (logbook, benchsheet, etc.) must be established for recording the serial number of the Weight Set used for CCV verification.
  - 12.1.2 Prior to, and after each analytical batch, drying oven temperature check(s) and

STANDARD OPERATING PROCEDURE ALS   Environmental - Kelso	Suspended Solids Determination
	GEN-TSS Rev. 14.0
	Effective: 6/10/2019
	SOP Review: 2/18/2021
	Page 7 of 9

time(s) shall be recorded on the benchsheet.

#### 12.1.3 QC Samples Required:

12.1.3.1 Run a Laboratory Control Sample per analytical batch of 20 samples. Calculate the LCS recovery as follows:

$$\%R = X/TV \times 100$$

Where X = Concentration of the analyte recovered  
TV = True value of amount spiked

12.1.3.2 Run a Method Blank every ten samples.

12.1.3.3 Run one duplicate per batch of ten samples.

#### 12.2 Acceptance Criteria

12.2.1 Balance calibration verification measured weights must be  $\pm 0.5\%$  of the true value.

12.2.2 The Method Blank should be < MRL.

12.2.3 Duplicates should have an RPD  $\pm 5\%$ .

Calculate Relative Percent Difference (RPD) as:

$$\%RPD = \frac{|R1 - R2|}{(R1 + R2)/2} \times 100$$

Where R1= Higher Result  
R2= Lower Result

### 13) Data Reduction and Reporting

13.1 Calculate TSS as follows:

$$mg \text{ total suspended solids} / L = \frac{(A - B) \times 1000}{\text{sample volume, mL}}$$

Where: A = weight of dried residue + filter, mg  
B = weight of pre-washed filter, mg.

13.2 Data Review and Assessment

		Suspended Solids Determination
	STANDARD OPERATING PROCEDURE	GEN-TSS Rev. 14.0
	ALS   Environmental - Kelso	Effective: 6/10/2019
		SOP Review: 2/18/2021
		Page 8 of 9

13.2.1 Following primary data interpretation and calculations, all data is reviewed by a secondary analyst. Following generation of the report, the report is also reviewed. Refer to the *SOP for Laboratory Data Review Process (ADM-DREV)* for details. The person responsible for final review of the data report and/or data package should assess the overall validity and quality of the results and provide any appropriate comments and information to the Project Manager for inclusion in the report narrative.

13.2.2 It is the analyst's responsibility to review analytical data to ensure that all quality control requirements have been met for each analytical run. Results for QC analyses are calculated and recorded as specified in this SOP. Average, RPD, spike level and spike recovery are entered on the analytical spreadsheet for corresponding samples. All data will be initialed, dated and attached to required data quality worksheet.

### 13.3 Reporting

13.3.1 Refer to the SOP for *Data Reporting and Report Generation (ADM-RG)* for reporting guidelines

13.3.2 The analyst enters data directly into ALSLIMS templates. An Analytical Results Summary is generated for that analytical batch showing all QC and sample results. After primary and secondary review, final reports are generated in ALSLIMS by compiling the SMO login, sample prep database, instrument date, and client-specified report requirements (when specified). The forms generated may be ALS standard reports, DOD, or client-specific reports. The compiled data from LIMS is also used to create EDDs.

13.3.3 Report in mg/L Total Suspended Solids using whole numbers.

13.3.4 The Method Reporting Limit is 5 mg/L for 200 mL samples and 2 mg/L for 500 mL samples.

13.3.5 The final report is reviewed by the department manager or designee.

## 14) Method Performance

14.1 This method was validated through single laboratory studies of accuracy and precision. Refer to the reference method for additional method performance data available.

## 15) Pollution Prevention and Waste Management

15.1 The laboratory will comply with all Federal, State, and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS-Kelso Lab Waste Management Plan.

## 16) Corrective Actions for Out-of-Control Data or Unacceptable Data

16.1 Refer to the SOP for *Nonconformance and Corrective Action Procedures (ADM-NCAR)* for procedures for corrective action.

		Suspended Solids Determination
	STANDARD OPERATING PROCEDURE	GEN-TSS Rev. 14.0
	ALS   Environmental - Kelso	Effective: 6/10/2019
		SOP Review: 2/18/2021
		Page 9 of 9

16.2 Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

## 17) Training

17.1 All analysts performing this analysis are required to read and understand this SOP.

17.2 Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

17.3 It is required that an initial demonstration of capability and periodic analysis of laboratory reagent blanks, laboratory fortified blanks, and other QC solutions as a continuing check on performance.

## 18) Method Modifications

18.1 There are no known notifications in this laboratory standard operating procedure or from the referenced method.

## 20) Summary of Changes

Revision Number	SOP Review	Document Editor	Description of Changes
14.0		T. Caron	Admin Changes only not affecting technical content. Documented date of annual SOP Review, updated SOP signatories; boiler plate standard paragraphs have been updated to reflect current practices. Section 19: Updated References.
14.0	J Coronado 2/18/2021		Reviewed and approved; no technical changes at this time.

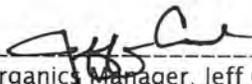

## 21) Attachments and Appendices

21.1 Not Applicable.

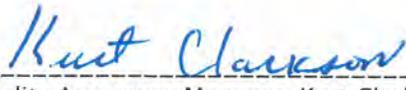

## Metals Digestion

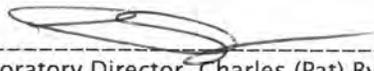

DOCUMENT ID: MET-3050B, REV. 18.0

Approved By:   
Inorganics Manager, Jeff Coronado

Date: 12/1/20

Approved By:   
Quality Assurance Manager, Kurt Clarkson

Date: 12/1/2020

Approved By:   
Laboratory Director, Charles (Pat) Byrne

Date: 12-1-20

## 1) Scope & Applicability

- 1.1 This procedure describes Method 3050B for acid digestion of sediments, sludges, and soil samples for analysis by ICP-OES (Methods 6010 and 200.7), and ICP-MS (Methods 200.8 and 6020). This procedure is not a total digestion technique, but extracts “environmentally available” elements from the sample of interest.
- 1.2 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP specific requirements to the laboratory. In general, project specific QAPPs supersede method specified requirements. An example of this are projects falling under DOD ELAP. QC requirements defined in the SOP *Department of Defense Projects – Laboratory Practices and Project Management*, may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 One-gram equivalent dry weight sediment, sludge, or soil samples are digested with repeated additions of nitric acid (HNO<sub>3</sub>) and hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>). Hydrochloric acid (HCl) is added to the initial digestate and the sample is refluxed prior to dilution to a final volume of 100 mL.

## 3) Definitions

- 3.1 For laboratory definitions applicable to most analyses, refer to the SOP for *Sample Batches*.

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. Final review and sign-off of the data is performed by the department supervisor/manager or designee.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency, as described in the *SOP Employee Training and Orientation*.

## 5) Interferences

- 5.1 Refer to the determinative method for a discussion of interferences.

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Kelso Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.
- 6.2 Hydrochloric and/or Nitric Acid are used in this method. These acids are extremely corrosive and care must be taken while handling them. A face shield should be used while pouring acids. And safety glasses should be worn while working with the solutions. Lab coat and gloves should always be worn while working with these solutions.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Samples may be collected in plastic or glass jars. Non-aqueous samples are refrigerated at  $4 \pm 2^\circ\text{C}$  from receipt until analysis.
- 7.2 The recommended holding time is 6 months from the day of sampling.

## 8) Apparatus and Equipment

- 8.1 125 mL plastic cup beaker cup - Environmental Express®.
- 8.2 Plastic watch glasses - Environmental Express®.
- 8.3 Block Digester, calibrated to maintain  $95 \pm 2^\circ\text{C}$ .
- 8.4 Laboratory balance, top-loader capable of reading 0.01 g.
- 8.5 USS # 10 sieve.
- 8.6 Infrared Thermometer.

## 9) Standards, Reagents, and Consumable Materials

- 9.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Refer to the SOP: *Reagent and Standards Login and Tracking*, for the complete procedure and documentation requirements.
- 9.2 All stocks, working solutions and sample dilutions should be prepared using deionized water (DI) conforming to ASTM Type I or ASTM Type II reagent water. For more information on reagent water generation, refer to the related SOP, Operation and Maintenance of Laboratory Reagent Water Systems.
- 9.3 Reagent water - ASTM Type I water (resistivity  $\geq 18 \text{ M}\Omega\text{-cm}$ , conductivity  $\leq 0.056 \text{ uS/cm}$ ).
- 9.4 Concentrated Nitric Acid - J.T. Baker "Instra-analyzed", Trace Metals Grade.
- 9.5 "Concentrated Hydrochloric Acid - J.T. Baker, "Baker Analyzed" ACS Reagent.
- 9.6 Hydrogen Peroxide (30%) - EMD GR ACS.
- 9.7 Standards
  - 9.7.1 Stock standards may be purchased from a number of vendors. All reference standards, where possible, must be traceable to SI units or NIST certified reference materials. The vendor assigned expiration date is used.
  - 9.7.2 Metals spiking solutions: Five spiking solutions are needed to prepare the matrix spike sample; SS1, SS2, SS3, SS4, and SS5.
  - 9.7.3 Follow the formulations laid out on the "Metals Spike Form. These solutions are prepared in acid rinsed Class A volumetric flasks using purchased custom mixed standards or 1000 ppm single analyte standards. Aliquots are made using acid rinsed Class A volumetric pipettes of the appropriate size.
  - 9.7.4 SS1 ( Al, Ag, Ba, Be, Cd, Co, Cr, Cu, Fe, Pb, Mn, Ni, Sb, V, and Zn): Fill a 1000 mL volumetric flask approximately half full with reagent water, add 50 mL of nitric acid and mix. Next add 100 mL of the custom mixed standard (CAS-CAL-14) purchased from "Inorganic Ventures". In addition add 50 mL of 1000 ppm

Antimony (use the Antimony standard that does not contain HCL.) Dilute to volume with reagent water, mix thoroughly and transfer to a 1000 mL Teflon bottle for storage. The solution expiration date is determined by the earliest expiration date of any single component in the solution.

- 9.7.5 SS2 (As, Cd, Cu, Pb, Se, Tl): Fill a 500 mL volumetric flask approximately half full with reagent water, add 25 mL of nitric acid and mix. Next add 2.0 mL each of 1000 ppm Arsenic, Cadmium, Copper, Lead, Selenium, and Thallium. Dilute to volume with reagent water, mix thoroughly and transfer to a 500 mL Teflon bottle for storage. The solution expiration date is determined by the earliest expiration date of any single component in the solution.
- 9.7.6 S3 (As, Se, Tl, and Hg): Fill a 500 mL volumetric flask approximately half full with reagent water, add 25 mL of nitric acid and mix. Next add 50 mL each of 1000 ppm Arsenic and Selenium. Next add 10 mL of 1000 ppm Thallium. Add 6.0 mL of 1000 ppm Hg. Dilute to volume with reagent water, mix thoroughly and transfer to a 500 mL Teflon bottle for storage. The solution expiration date is determined by the earliest expiration date of any single component in the solution.
- 9.7.7 SS4 (B, Mo,U): Fill a 500 mL volumetric flask approximately half full with reagent water, add 25 mL of nitric acid and mix. Next add 25 mL of 1000 ppm Boron, 50mL of 1000 ppm Molybdenum and 10 mL of 1000 ppm Uranium. Dilute to volume with reagent water, mix thoroughly and transfer to a 500 mL Teflon bottle for storage. The solution's expiration date is determined by the earliest expiration date of any single component in the solution.
- 9.7.8 SS5 (K, Na, Mg, Ca): Fill a 200 mL volumetric flask approximately half full with reagent water add 10.0 mL of nitric acid and mix. Next add 20 mL each of 10,000 ppm Potassium, Sodium, Magnesium and Calcium. Dilute to volume with reagent water, mix thoroughly and transfer to a 250 mL Teflon bottle for storage. The solution's expiration date is determined by the earliest expiration date of any single component in the solution.
- 9.8 Metals reference material (ERA Priority PollutnT/CLP Inorganic Soil) for use as the laboratory control sample. The expiration date is assigned by the manufacturer.
- 9.9 Teflon beads, Teflon boiling chips, or other suitable blank material.

## 10) Preventative Maintenance

- 10.1 All maintenance activities are recorded in a maintenance logbook kept for each instrument. Pertinent information (serial numbers, instrument I.D., etc.) must be in the logbook. This includes the routine maintenance described herein. The entry in the log must include: date of event, the initials of who performed the work, and a reference to analytical control.
- 10.2 Maintenance for this procedure is generally limited to glassware cleaning, pipette monitoring, and hot plate calibration. Procedures for glassware washing are described in the SOP for *Metals Laboratory Glassware Cleaning*. Procedures for pipette monitoring are given in the SOP *Checking Volumetric Labware*.
- 10.3 Each block digester is uniquely identified and the temperature is verified with each batch of samples. The temperature is turned to the 95°C setting and the block is allowed to come to temperature. The analyst will verify that the block gives a temperature of  $95 \pm 2^\circ\text{C}$  using a semi-annually-calibrated traceable handheld infrared

thermometer. If not at the right temperature, the thermostat is adjusted until the IR thermometer reads  $95 \pm 2^\circ\text{C}$ .

## 11) Procedure

- 11.1 Record all digestion and sample information on the applicable benchsheet.
- 11.2 Mix the sample thoroughly to achieve homogeneity. Sieve if necessary using a USS #10 sieve.
- 11.3 It can be difficult to obtain a representative sample with wet or damp materials. As per Method 3050B, wet samples may be dried, crushed, and ground to reduce subsample variability, however, drying is not recommended since drying may affect the extraction of the analytes of interest in the sample.
- 11.4 Weigh approximately 1 g of sample into a 125 mL plastic beaker cup and record the weight to the nearest 0.01 g. For sludge's and sediments that have high moisture content, use more sample. A plastic 10.0 mL disposable pipette is used to measure 10.0 mL of sample. The volume and weight of the pipetted sample is recorded. In cases where the sludge is very thick a 10.0 mL graduated cylinder may be used. The objective is to use about 1 g of dry weight sample. This will achieve a lower detection limit needed for most projects. At this point add the appropriate spiking solutions directly onto the designated spike sample prior to addition of reagents.
- 11.5 Add 5ml reagent water and 5ml concentrated  $\text{HNO}_3$ . Place in a hot block, cover and reflux (without boiling) at  $95^\circ\text{C}$  for 10 to 15 minutes. Allow the sample to cool. Add 5ml of concentrated  $\text{HNO}_3$ , cover and reflux for 30 minutes. If brown fumes are generated, indicating oxidation of the sample by  $\text{HNO}_3$ , repeat the addition of 5ml of  $\text{HNO}_3$  and reflux over and over until no brown fumes are given off. Digest for 45 minutes or until the Brown fumes have ceased.  

<sup>1</sup>Note: The  $95^\circ\text{C}$  hot block temperature must be monitored and documented on a per batch basis.

<sup>2</sup>Note: All Wisconsin samples must digest for 2 hours after generation of brown fumes has ceased.

<sup>3</sup>Note: Wipe samples do not require the final two hour digestion.
- 11.6 Cool the sample and add 3 mL of 30%  $\text{H}_2\text{O}_2$ . Cover and heat to start the peroxide reaction. Care must be taken to ensure that losses do not occur due to excessive effervescence. Heat in the hot block until effervescence subsides. Remove from hot block and cool the beaker.
- 11.7 Continue to add 30%  $\text{H}_2\text{O}_2$  in 3 mL aliquots with warming until the effervescence is minimal, or until the general sample appearance is unchanged. Do not add more than 10 mL of 30%  $\text{H}_2\text{O}_2$ . When the peroxide additions are complete cover the sample with a watch glass and continue heating the acid-peroxide digestate until the volume has been reduced to approximately 5-10 mL or heat at  $95 \pm 2^\circ\text{C}$  without boiling for 2 hours. Do not let the samples go to dryness, by ensuring the solution covers the bottom of the vessel at all times.
  - 11.7.1 Add 10 mL of concentrated HCl. Cover and reflux for 15 minutes at  $95 \pm 2^\circ\text{C}$ . After cooling, the samples may be diluted to 100 mL with ASTM Type I reagent water (resistivity  $>18 \text{ M}\Omega\text{-cm}$ , conductivity  $<0.056 \text{ uS/cm}$ ) in a 125 mL plastic beaker cup.

- 11.8 Particulates in the digestates that may clog the nebulizer are allowed to settle overnight, or the digestates may be centrifuged.
- 11.9 To improve the solubility for Antimony, Barium, Lead and Silver, the following modification of the digestion procedure may be used as directed by the client or project manager.
- 11.10 Weigh (to the nearest 0.01 g) 1.00 g of sample into a 125 mL plastic cup. For sludges and sediments that have high moisture content, use more sample. The objective is to use about 1 g of dry weight sample.
- 11.11 Add 2.5 mL HNO<sub>3</sub> and 10 mL HCl and cover with a watch glass. Reflux for 15 minutes.
- 11.12 Filter the digestate through Whatman No. 41 or equivalent filter paper and collect in a 100 mL volumetric flask. Wash the filter paper, while still in the funnel, with no more than 5 mL of hot (95°C) HCl, and then with 20 mL of hot (95°C) reagent water. Collect washing in the same volumetric flask.
  - 11.12.1 Remove the filter and residue from the funnel, and place them back in the beaker. Add 5 mL HCl, cover and heat at 95 ± 5°C until the filter paper dissolves. Remove from the heat and wash the cover and sides with reagent water.
  - 11.12.2 Filter the residue and collect the filtrate in the same 100 mL flask. Allow to cool, then dilute to volume.
  - 11.12.3 If precipitation occurs in the flask upon cooling, do not dilute to volume. Instead, add up to 10 mL of HCl to dissolve the precipitate. After precipitate is dissolved, dilute to volume with water.

## 12) QA/QC Requirements

- 12.1 Initial Precision and Recovery Validation
  - 12.1.1 The accuracy and precision of the procedure must be validated before analyses of samples begin, or whenever significant changes to the procedures have been made. To do this, four blank matrix samples are spiked with the LCS spike solution, then prepared and analyzed.
- 12.2 Monitor Hot Blocks and Hotplates on a per batch basis. Report all deficiencies to the Lab Manager. Corrective action must be taken.
- 12.3 Digest one laboratory control sample with each batch. Weigh 1.00 g of the current lot of Environmental Resource Associates PriorityPollutant/CLP Inorganic Soil prepared reference material into a 150 mL beaker and digest as per the procedure.
- 12.4 Digest one preparation blank (method blank) per digestion batch, or per 20 samples whichever is more frequent. For the method blank, use Teflon beads, Teflon boiling chips, or other suitable solid blank material and follow the digestion procedures.
- 12.5 Digest one duplicate and one spiked sample with each sample matrix. Prepare one duplicate and spike sample per each digestion batch, or per twenty samples whichever is more frequent. At times, specific samples will be assigned as duplicates of spikes depending on client requirements.
- 12.6 Soil spikes for ICP and ICP-MS are prepared by adding 2.0 mL of SS1, and 1.0 mL of SS3, SS4 and SS5 directly to the sample aliquot, prior to the addition of any water or acid. Fill out a spiking data sheet and keep it with the digestion data sheets.

### 13) Data Reduction and Reporting

- 13.1 Digestion data sheets including weights and volumes used and reagents/acids are completed and a prep run number or batch lot number is assigned and attached to the data sheet. The lot numbers for the reagents used are added to the digestion data sheet.
- 13.2 Spiking sheets are included.
- 13.3 Following primary data interpretation and calculations, all data is reviewed by a secondary analyst. Following generation of the report, the report is also reviewed. Refer to the SOP for *Laboratory Data Review Process* (ADM-DREV) for details. The person responsible for final review of the data report and/or data package should assess the overall validity and quality of the results and provide any appropriate comments and information to the Project Manager to inclusion in the report narrative.
  - 13.3.1 It is the analyst's responsibility to review analytical data to ensure that all quality control requirements have been met for each analytical run. Results for QC analyses are calculated and recorded as specified in this SOP. Average, RPD, spike level and spike recovery are entered on the analytical spreadsheet for corresponding samples. All data will be initialed, dated and attached to required data quality worksheet.

### 14) Contingencies for Handling Out-of-Control or Unacceptable Data

- 14.1 Refer to the SOP for *Nonconformance and Corrective Action Procedures* for corrective action.
- 14.2 Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

### 15) Method Performance

- 15.1 Available method performance data is given in the reference method. In addition, this procedure was validated through single laboratory studies of accuracy and precision as in the determinative procedure. The method detection limit(s) and method reporting limit(s) are established for the determinative procedure. See *Performing and Documenting Method Detection Limit Studies and Establishing Limits of Detection and Quantitation*.

### 16) Pollution Prevention and Waste Management

- 16.1 It is the laboratory's practice to minimize the amount of solvents, acids and reagent used to perform this method wherever feasible. Standards are prepared in volumes consistent with methodology and only the amount needed for routine laboratory use is kept on site. The threat to the environment from solvent and reagents used in this method can be minimized when recycled or disposed of properly.
- 16.2 The laboratory will comply with all Federal, State and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.
- 16.3 This method uses acid. Waste acid is hazardous to the sewer system and to the environment. All acid waste must be neutralized prior to disposal down the drain. The neutralization step is considered hazardous waste treatment and must be documented on the treatment by generator record. See the ALS Chemical Hygiene Plan for details.

### 17) Training

- 17.1 All analysts performing this analysis are required to read and understand this SOP. Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

### 18) Method Modifications

- 18.1 The method uses 2 mL of water and 3 mL of H<sub>2</sub>O<sub>2</sub>. The lab does not add the 2 mL of water. 3.0 mL aliquots of 30% H<sub>2</sub>O<sub>2</sub> in lieu of 1.0 mL aliquots are added subsequently.

### 19) References

- 19.1 Test Methods for Evaluating Solid Waste, Physical/Chemical Methods. EPA SW-846, 3rd Edition, Final Update III, Method 3050B, December 1996.

	STANDARD OPERATING PROCEDURE	Metals by ICP-MS (6020)
	ALS   Environmental – Kelso	MET-6020, Rev. 19.0
		Effective: 12/2/2020
		Page 2 of 22

## 1) Scope & Applicability

- 1.1 This procedure is used to determine the concentrations of certain elements in water, soil, tissues, aqueous and non-aqueous wastes, and sediment samples using EPA Method 6020B. The Kelso DQO table indicates analytes that are typically determined by this procedure and lists the standard Method Reporting Limits (MRLs) for each analyte in water and soil. Project-specific MRLs may apply, and if lower than standard MRLs, it is demonstrated through method detection limit determinations and analysis of MRL standards that the MRL is achievable. Method Detection Limits are referenced in the laboratory DQO tables and may change as new studies are performed.
- 1.2 The complexity of the technique generally requires outside study of appropriate literature as well as specialized training by a qualified spectroscopist. The scope of this document does not allow for the in-depth descriptions of the relevant spectroscopic principles required for gaining a complete level of competence in this scientific discipline.
- 1.3 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DoD ELAP. QC requirements defined in the SOP *Department of Defense Projects – Laboratory Practices and Project Management* (ADM-DOD5) may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 Prior to analysis, samples must be digested using appropriate sample preparation methods. The digestate is analyzed for the elements of interest using ICP-mass spectrometry (ICP-MS).
- 2.2 Methods 6020B describe the multi-elemental determination of analytes by ICP-MS. The method measures ions produced by a radio-frequency inductively coupled plasma. Analyte species originating in a liquid are nebulized and the resulting aerosol transported by argon gas into the plasma torch. The ions produced are entrained in the plasma gas and introduced, by means of an interface, into a mass spectrometer. The ions produced in the plasma are sorted according to their mass-to-charge ratios and quantified with a channel electron multiplier. Interferences must be assessed and valid corrections applied or the data flagged to indicate problems. Interference correction must include compensation for background ions contributed by the plasma gas, reagents, and constituents of the sample matrix.

## 3) Definitions

- 3.1 For environmental laboratory quality definitions, guidance on analytical calibration and sample batches, refer to the SOP for Sample Batches, ADM-BATCH.

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP

	STANDARD OPERATING PROCEDURE	Metals by ICP-MS (6020)
	ALS   Environmental – Kelso	MET-6020, Rev. 19.0
		Effective: 12/2/2020
		Page 3 of 22

and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. Final review and sign-off of the data is performed by the department supervisor/manager or designee.

- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency, as described in the ALS-Kelso *SOP for Training Procedure* (ADM-TRAIN).

## 5) Interferences

- 5.1 Isobaric elemental interferences in ICP-MS are caused by isotopes of different elements forming atomic ions with the same nominal mass-to-charge ratio (m/z). A data system must be used to correct for these interferences. This involves determining the signal for another isotope of the interfering element and subtracting the appropriate signal from the analyte isotope signal. Attention should be given to circumstances where very high ion currents at adjacent masses may contribute to ion signals at the mass of interest. Matrices exhibiting a significant problem of this type may require resolution improvement, matrix separation, or analysis using another isotope.
- 5.2 Isobaric molecular and doubly-charged ion interferences in ICP-MS are caused by ions consisting of more than one atom or charge, respectively. Most isobaric interferences that could affect ICP-MS determinations have been identified in the literature. Refer to Method 6020B for further discussion.

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.
- 6.2 Nitric Acid and Hydrochloric Acid is used in this method. These acids are extremely corrosive and care must be taken while handling them. A face shield, safety goggles, lab coat and gloves must be used while pouring acids. When working with solutions less than 20%, then a lab coat, goggles and gloves must always be worn.
- 6.3 High Voltage - The RF generator supplies up to 2000 watts to maintain an ICP. The power is transferred through the load coil located in the torch box. Contact with the load coil while generator is in operation will likely result in death. When performing maintenance on the RF generator, appropriate grounding of all HV capacitors must be performed as per manufacturer.
- 6.4 UV Light - The plasma is an intense source of UV emission, and must not be viewed with the naked eye. Protective lenses are in place on the instrument. Glasses with special protective lenses are available when direct viewing of the plasma is necessary.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Aqueous samples are typically collected in plastic containers. Aqueous samples are preserved with nitric acid (pH<2), then stored at room temperature from

	STANDARD OPERATING PROCEDURE	Metals by ICP-MS (6020)
	ALS   Environmental – Kelso	MET-6020, Rev. 19.0
		Effective: 12/2/2020
		Page 4 of 22

receipt until digestion. Soil or solid samples may be collected in plastic or glass jars. Non-aqueous samples are refrigerated at  $4 \pm 2^{\circ}\text{C}$  from receipt until digestion.

- 7.2 Samples are prepared via procedures in SOPs MET-DIG, MET-3020A, MET-3050, MET-3051M, MET-3052M, or MET-TDIG depending on matrix and project specifications.
- 7.3 Digestates are stored in the appropriate containers. Following analysis, digestates are stored until all results have been reviewed. Digestates are neutralized prior to disposal through the sewer system, 2 weeks after data is reviewed.

## 8) Standards, Reagents, and Consumable Materials

- 8.1 All standards are prepared from NIST traceable standards. The expiration dates are assigned according to the EPA method and the vendor's assigned expiration dates.

- 8.1.1 1000 ppm Single Element Stock Standard Solutions: Each stock standard is stored at room temperature on shelves located in room 113 of the metals lab. The manufacturer, lot number, and expiration date of each stock standard is recorded in a bound logbook also located in room 113. Additionally each stock standard is given a unique, identifying name.

- 8.1.2 Intermediate Standard Solutions: Intermediate mixed stock solutions are made from the individual stock standards described above. The individual component of each mixed solution is recorded in a bound logbook located in the ICP-MS laboratory and mixed solution is given a unique, identifying name. The expiration date for the intermediate standard is the earlier of any one of its stock components.

- 8.1.3 Calibration Standards: Calibration standards are made fresh daily from the intermediate standard solutions. Each individual intermediate standard used in the calibration standard is recorded in a bound logbook located in the ICP-MS laboratory, and the calibration standard solution is given a unique, identifying name. The calibration standards unique name is used on the raw data to link the data to the subsequent prepared standards and ultimately the original purchased stock standard.

- 8.2 Standards Preparation

- 8.2.1 Expiration of all standard solutions defaults to the earliest expiration date of an individual component unless otherwise specified.

- 8.2.2 Calibration Standards

The calibration standard is prepared from two intermediate stock solutions. These solutions are prepared in acid rinsed 1000 mL Class A volumetric flasks following the formulations laid out on the attached example standard sheet (see Attachments). The working calibration standard is made daily by aliquoting 2.5 mL of each of the intermediate solutions in to a 100 mL Class A volumetric flask and diluting to volume with DI water and the appropriate acid(s). This standard is also used as

	STANDARD OPERATING PROCEDURE	Metals by ICP-MS (6020)

		Effective: 12/2/2020
		Page 5 of 22

the Continuing Calibration Verification (CCV).

### 8.2.3 Initial Calibration Verification (ICV)

8.2.3.1 The ICV intermediate stock solution is prepared in an acid rinsed 100 mL Class A volumetric flask. The solution is prepared by adding 2.0 mL of Inorganic Ventures QCP-CICV-1, 1.0 mL of QCP-CICV-3, 0.5 mL of 1000 ppm Boron, Bismuth, Molybdenum, Strontium, Titanium, and Uranium stock solutions, 0.25 mL of 1000 ppm Antimony stock solution and diluting to volume with the appropriate acid matrix.

8.2.3.2 The working ICV solution is prepared by aliquoting 0.5 mL of the mixed ICV intermediate solution and 0.25 mL of 10 ppm Tin standard into an acid rinsed 100 mL Class A volumetric flask and diluting to volume with the appropriate acid matrix.

**NOTE:** The ICV solution is not at the midpoint of the linear range which may be as high as 1000 µg/L for some elements. The ICV solution used is a premixed standard purchased from Inorganic Ventures and contains the elements of interest between 2.5 and 100 µg/L. This solution provides calibration confirmation at more representative levels, given that most ICP-MS analyses are quantifying analytes in the low-ppb to sub-ppb range.

### 8.2.4 Interference Check Solutions (ICSA and ICSAB)

8.2.4.1 The ICSA is prepared in an acid rinsed 50 mL Class B volumetric flask by aliquoting 1.0 mL of Elements ICSAm (CS-CAK02) and 0.250 mL of 10 ppm molybdenum solutions and diluting to volume with the appropriate acid matrix.

8.2.4.2 The ICSAB is prepared in an acid rinsed 50 mL Class B volumetric flask by aliquoting 1.0 mL of Elements ICSAm (CS-CAK02), 0.125 mL of Inorganic Ventures 6020ICS-9B, and 0.250 mL of 10 ppm Molybdenum solutions and diluting to volume with the appropriate acid matrix.

8.2.5 Post-digestion spikes are performed by adding appropriate amounts of the calibration intermediate solutions to aliquots of the sample digestate. The volumes of each standard used vary based on the native concentrations found in the field samples. Refer to the post-digestion spike in Section 12 for details.

8.2.6 Refer to the appropriate digestion SOP for details of LCSW and matrix spike solution composition and preparation.

### 8.2.7 Tuning / Mass Calibration Solution

8.2.7.1 A 1 ppm intermediate solution containing Be, Bi, Ce, Co, In, Li, Pb, Mg, and U is prepared by adding 1.0 mL of each from 1000

	STANDARD OPERATING PROCEDURE	Metals by ICP-MS (6020)
	ALS   Environmental – Kelso	MET-6020, Rev. 19.0
		Effective: 12/2/2020
		Page 6 of 22

ppm stock standards to an acid rinsed 1000 mL volumetric flask and diluting to volume with 1% nitric acid. The expiration date for the intermediate solution is the earlier of any one of its stock components.

8.2.7.2 The working solution is prepared in depending upon the instrument:

- For the Agilent: a 10 ppb tune/mass calibration solution is prepared by adding 10 mL of intermediate solution to an acid rinsed 1000 mL volumetric flask and diluting to volume with the appropriate acid matrix.
- For the NexION (K-ICP-MS-04) instrument a 2.0 ppb tune/mass calibration solution is prepared by adding 2.0 mL of intermediate solution to an acid rinsed 1000 mL volumetric flask and diluting to volume with the appropriate acid matrix.

The expiration date for this solution is taken from the intermediate stock above.

8.3 Internal Standards Stock Solution – Prepare solutions by adding appropriate amounts of each 1000 ppm single element stock solution to an acid rinsed 1000 mL volumetric flask and diluting to volume with 1% nitric. The internal standard solution is teed in by the peristaltic pump and used for the entire analytical sequence. The typical solutions are:

- Agilent Instrument: 1 ppm, Sc, Y, Ge, Ce, Tm, In, Lu, Th; 0.2 ppm <sup>6</sup>Li.
- NexION instrument: 30 ppb In, Tm, Lu, Th; 60 ppb <sup>6</sup>Li, Rh, Au; 75 ppb Sc; 100 ppb Ga, Y; 500 ppb Ge.

8.4 Additional Reagents

8.4.1 Reagent water, ASTM Type II.

8.4.2 All stocks, working solutions and sample dilutions should be prepared using deionized water (DI) conforming to ASTM Type I or ASTM Type II reagent water. For more information on reagent water generation, refer to the related SOP, Operation and Maintenance of Laboratory Reagent Water Systems.

8.4.3 “OmniTrace Ultra” Concentrated Nitric Acid (EM Science # NX0408-2).

8.4.4 Argon (Airgas Industrial Grade – 99.999% pure, bulk delivered).

## 9) Apparatus and Equipment

9.1 ICP/MS Instruments

9.1.1 Instrument: NexION 300D  
Nebulizer: PFA-ST Microflow  
Spray Chamber: Cyclonic, Peltier-cooled  
Cones: Nickel Sampler (1.0 mm orifice)

	STANDARD OPERATING PROCEDURE	Metals by ICP-MS (6020)
	ALS   Environmental – Kelso	MET-6020, Rev. 19.0
		Effective: 12/2/2020
		Page 7 of 22

Nickel Skimmer (0.75 mm orifice)

9.1.2 Instrument: Agilent 7700  
Nebulizer: MicroMist  
Spray Chamber: Double Pass quartz spray chamber  
Cones: Nickel Sampler (1.0 mm orifice)  
Nickel Skimmer (0.75 mm orifice)

9.1.3 Instrument: Agilent 7800  
Nebulizer: MicroMist  
Spray Chamber: Cyclonic, Peltier-cooled  
Cones: Nickel Sampler (1.0 mm orifice)  
Nickel Skimmer (0.75 mm orifice)

## 10) Preventative Maintenance

10.1 All maintenance is documented in the instrument logbook. ALS/Kelso maintains a service contract with the instrument manufacturer that allows for an unlimited number of service calls and full reimbursement of all parts and labor.

10.2 Most routine maintenance and troubleshooting is performed by ALS staff. Preventive maintenance activities listed below should be performed when needed as determined by instrument performance (i.e. stability, sensitivity, etc.) or by visual inspection. Other maintenance or repairs may, or may not require factory service, depending on the nature of the task.

- cone removal and cleaning
- removal and cleaning of ICP glassware and fittings
- checking and cleaning RF contact strips
- checking air filters and cleaning if necessary
- checking the oil mist filters and cleaning if necessary
- checking the rotary pump oil and adding or changing if necessary
- removal and cleaning of extraction lens
- removal and cleaning of ion lens stack
- replace the electron multiplier as necessary

## 11) Procedure

11.1 Refer to method 6020B and the instrument manuals for detailed instruction on implementation of the following daily procedures preceding an analytical run.

11.2 The following parameters are monitored to assure awareness of changes in the instrumentation that serve as signals that optimum performance is not being achieved, or as indicators of the physical condition of certain consumable components (i.e. EMT and cones).

11.2.1 Multiplier Voltages

11.2.2 Gas Flows - Coolant Ar

	STANDARD OPERATING PROCEDURE	Metals by ICP-MS (6020)
	ALS   Environmental – Kelso	MET-6020, Rev. 19.0
		Effective: 12/2/2020
		Page 8 of 22

11.2.3 The nebulizer and auxiliary flows are adjusted later as part of the optimizing procedure.

### 11.3 Optimization

#### 11.3.1 Gas Flows

11.3.1.1 Allow a period of not less than 30 minutes for the instrument to warm up.

11.3.1.2 Aspirate a mixed tune solution into the plasma and monitor the instrument output signal at mass 115 on the rate meter. Adjust the nebulizer and auxiliary flows to obtain maximum signal. Adjust the tension screw on the peristaltic pump to obtain minimum noise in the analytical signal. Record flow rates and note any large variances.

Note: Significant differences in flow rates will be observed for different torches and cones.

#### 11.3.2 Tuning

11.3.2.1 Ion Lens Setting - While monitoring the output signal of a mixed tune solution at mass 115 on the rate meter, adjust the ion lenses to obtain maximum sensitivity. Refer to the instrument manual for details on performing the adjustments.

11.3.2.2 Mass Calibration - Aspirate the tune / mass calibration solution described in section 8.2.7.2 and perform the mass calibration using the instrument's Mass Calibration program. (Refer to the instrument manual for details pertaining to the mass calibration procedure.) The acceptance criteria for the mass calibration is  $<0.1$  amu from the true value. If the mass calibration fails criteria re-tune the instrument and perform the mass calibration procedure again.

11.3.2.3 Resolution Check - Using the spectra created during the mass calibration procedure; perform the resolution check to assure the resolution is less than 0.9 AMU at 5% peak height. If the resolution does not pass criteria adjust the instrument's resolution settings, run a new scan of the mass calibration solution and recheck.

11.3.2.4 Stability Check - Using the tune / mass calibration solution, perform a short-term stability check as per EPA Method 6020B. The relative standard deviations of five scans for each element in the tune solution must be  $< 5\%$ . If the test does not pass criteria determine the cause (i.e. dirty cones, improper tune, etc.) correct the problem and re-run the test.

### 11.4 Analytical Run

11.4.1 Calibrate the instrument using a calibration blank (Standard 0), composed of reagent water, the appropriate acid matrix, and the working calibration standard (8.2.2). The masses typically monitored and those used for quantification are listed in Table 2. These masses are set as defaults in the instrument's analytical procedures. To begin select the correct method. Nebulize Standard 0 (Blank) into the plasma. Allow 1-2 minutes for system to equilibrate prior to establishing baseline. Follow directions on computer screen to perform standardization. Nebulize the working calibration standard into the plasma. The operator must sign and date the first page of standardization.

11.4.2 After the first CCB and before the ICS standards a LLCCV standard, at or below the LOQ, is analyzed. The LLCCV must recover between  $\pm 20\%$ .

11.4.3 Perform the analysis in the order listed below.

Initial Calibration Verification (ICV)  
Continuing Calibration Verification (CCV)  
Initial Calibration Blank (ICB)  
Continuing Calibration Blank (CCB)  
LLCCV  
ICSA  
ICSAB  
Analyze 10 Samples  
CCV  
CCB  
Analyze 10 Samples  
CCV  
CCB

Repeat sequence as required to complete analytical run, analyzing CCVs/CCBs every 10 analyses and at the end of the run.

11.4.4 Water samples with silver concentrations greater than 100 ug/L require confirmation from the original sample container to ensure silver has not been lost through precipitation in the digestate.

## 12) QA/QC Requirements

### 12.1 Initial Precision and Recovery Validation

12.1.1 The accuracy and precision of the procedure must be validated before analysis of samples begins, or whenever significant changes to the procedures have been made. To do this, four LCS aliquots are prepared and analyzed. The average percent recovery of for each analyte must be 85-115% (for water, and within the LCS limits for soils) and the RSD <20%.

	STANDARD OPERATING PROCEDURE	Metals by ICP-MS (6020)
	ALS   Environmental – Kelso	MET-6020, Rev. 19.0
		Effective: 12/2/2020
		Page 10 of 22

## 12.2 Method Detection Limits

12.2.1 A method detection limit (MDL) study must be undertaken before analysis of samples can begin. Refer to *Performing and Documenting Method Detection Limit Studies and Establishing Limits of Detection and Quantification* (ADM-MDL) for details of performing the MDL study.

12.2.2 Calculate the average concentration found (x) and the standard deviation of the concentrations for each analyte. Calculate the MDL for each analyte using the correct T value for the number of replicates. MDL's must be verified annually or whenever there is a significant change in the background or instrument response.

12.3 The LLQC is verified initially by the analysis of at least 7 replicate samples, spiked at the LLOQ. In most cases, the mean recovery should be  $\pm 35\%$  of the true value and the RSD should be  $< 20\%$ .

12.4 IDLs should be determined at least once using new equipment, or after major instrument maintenance. The IDL is determined as the mean of the blank results + three times the standard deviation of 10 replicate analyses of the reagent blank solution.

12.5 Method 6020B requires that the linear range for each wavelength be verified on a daily basis. The linear range verification must recover within 10% of the true value and can be analyzed anywhere within a particular run. If a linear range verification is not analyzed for a specific element, the highest calibration range becomes the linear range. All reporting sample measurements must fall within the linear range.

12.6 The Initial Calibration Verification (ICV) standard is analyzed immediately after calibration. The results of the ICV must agree within  $\pm 10\%$  of the expected value. If the control limits are exceeded, the problem will be identified and the instrument recalibrated.

12.7 A Continuing Calibration Verification (CCV) is analyzed after calibration then every 10 samples thereafter with a final CCV closing the final samples of the analytical run.

12.7.1 The results of the CCV must agree within  $\pm 10\%$  of the expected value.

12.7.2 If the control limits are exceeded, the problem will be identified and corrective action taken. The instrument recalibrated. The previous 10 samples must be reanalyzed.

12.8 A Continuing Calibration Blank (CCB) is analyzed after calibration then every 10 samples thereafter with a final CCB closing the final samples of the analytical run.

12.8.1 The CCB measured values must be less than the MRL / LOQ for each element for standard applications. Other project-specific criteria may apply (for DoD QSM projects CCB can have no analytes  $>$  the LOD).

- 12.9 The ICSA and ICSAB solutions are analyzed after calibration and before any field samples. The solutions are then reanalyzed every 12 hours. Results of the ICSA are used by the analyst to identify the impact of potential interferences on the quality of the data. Based on these results appropriate action should be taken when interferences are suspected in a field sample including, but not limited to, selecting an alternative isotope for quantification, manual correction of the data, elevating the MRL, selection of an alternative method (e.g. optical ICP) or flagging the result as estimated when no other action is possible. Results for the spiked analytes in the ICSAB solution must agree with  $\pm 20\%$  of the expected value.

#### INTERFERENCE CHECK SAMPLE COMPONENTS AND CONCENTRATIONS

	<u>Solution A</u> <u>Concentrations (mg/L)</u>	<u>Solution B</u> <u>Concentrations (mg/L)</u>
Al	20.0	20.0
Ca	60.0	60.0
Fe	50.0	50.0
Mg	20.0	20.0
Na	50.0	50.0
P	20.0	20.0
K	20.0	20.0
S	20.0	20.0
C	40.0	40.0
Cl	424	424
Mo	0.05	0.05
Ti	0.40	0.40
As	0.0	0.025
Cd	0.0	0.025
Cr	0.0	0.050
Co	0.0	0.050
Cu	0.0	0.050
Mn	0.0	0.050
Ni	0.0	0.050
Se	0.0	0.025
Ag	0.0	0.0125
V	0.0	0.050
Zn	0.0	0.025

**NOTE:** The concentration of interfering elements in the ICSA and ICSAB solutions are spiked at levels 5 times lower than recommended in Table 1 of Method 6020B. Running the full strength solutions as described in 6020B introduces too much material approximately 0.35 % dissolved solids into the ICP-MS system when trying to conduct low level analysis. Since the ICP-MS instrumentation is able to handle a maximum of 0.2% solids, the 6020B ICSA solution is higher in interfering components than any sample that would run through the instrument. However, the ICS solutions will be analyzed at levels that will provide approximately 0.1% dissolved solids.

	STANDARD OPERATING PROCEDURE	Metals by ICP-MS (6020)
	ALS   Environmental – Kelso	MET-6020, Rev. 19.0
		Effective: 12/2/2020
		Page 12 of 22

- 12.10 Internal standards are used to correct for physical interferences. Masses used as internal standards include;  $^{71}\text{Ga}$ ,  $^{72}\text{Ge}$ ,  $^{115}\text{In}$ ,  $^6\text{Li}$ ,  $^{175}\text{Lu}$ ,  $^{103}\text{Rh}$ ,  $^{45}\text{Sc}$ ,  $^{232}\text{Th}$ , and  $^{89}\text{Y}$ . These internal standards are used in combination to cover the appropriate mass ranges. Internal standard correction is applied to the analytical isotopes by direct correlation of analyte to IS (Agilent), (NexION). This function is performed in real-time by the instruments operating system. Internal standards must be run within 50 AMU of the masses that are analyzed. Internal standard recoveries must fall between 30% and 125%. If not, then the sample must be reanalyzed after a fivefold or greater dilution has been performed.
- 12.11 A method blank is digested and analyzed with every batch of 20 (or fewer) samples to demonstrate that there are no method interferences. If the method blank shows any hits above the MRL for standard applications, or  $> \frac{1}{2}$  the LOQ for DoD projects or  $> 1/10$  the sample result, corrective action must be taken. The MB can only be rerun once. Corrective action includes recalculation, reanalysis, system cleaning, or re-extraction and re-analysis,
- 12.12 Laboratory Control Samples are analyzed at a frequency of 5% or one per batch, whichever is greater. Refer to the current ALS-Kelso DQO spreadsheets for the LCS limits. For method 6020B, the LCS recovery limits are 80-120%. If statistical in-house limits are used, they must fall within the 80-120% range. Project, QAPP, or client-specific control limits may supersede the limits listed, but laboratory limits should be consistent with specified limits in order to establish that the specified limits can be achieved. If the control limits are exceeded, the associated batch of samples will be re-digested and reanalyzed.
- 12.13 A duplicate is digested one per batch, or per 20 samples (i.e. 5%). The duplicate RPD limits is  $\leq 20\%$ . Project, QAPP, or client-specific control limits may supersede the limits listed. If the control limits are exceeded, the samples will be re-digested and reanalyzed, unless sample non-homogeneity is established as the cause. In these instances, the data and the report will be flagged accordingly.
- 12.14 A Matrix Spike sample is digested one per batch, or per 20 samples (i.e. 5%). Default spike concentrations are listed in the sample digestion SOPs. Spike concentrations may be adjusted to meet project requirements. The matrix spike recovery will be calculated while the job is in progress. Where specified by project requirements, a matrix spike duplicate may be required. Matrix spike recovery criteria are derived from lab data. For Method 6020B, the recovery limits are 75-125%. If statistical in-house limits are used, they must fall within the 75-125% range. In some cases, project-specific QC limits may be required. Unless specified otherwise, for DoD QSM projects the project LCS criteria will be used for evaluation of matrix spikes. If an analyte recovery is outside acceptance limits proceed with the additional quality control tests described in sections 12.13 and 12.14. Based on results of these tests, the physical nature of the sample (e.g. homogeneity), and any specific project requirements, a determination can then be made as to appropriate corrective action (e.g. re-digestion, reporting with a qualifier, alternative methodologies, etc.). If the analyte concentration is  $> 4x$  the spike level the spike control limit is no longer applicable and no action is required. For specifics on the preparation and composition of matrix spike solutions refer to the appropriate digestion SOP.

**Note:** For DoD projects a MS/MSD is required with every extraction batch. The %RSD should be < 20%.

- 12.15 Post Digestion Spike Test: The post digestion spike test is performed whenever matrix spike or replicate criteria are exceeded. An analyte spike is added to a portion of a prepared sample, or its dilution, and should be recovered to within 75% to 125% of the known value. If this spike fails, then the dilution test should be run on this sample. If both the matrix spike and the post digestion spike fail, then matrix effects are confirmed. For DOD QSM 5.0 the post digestion spike shall be recovered to within 80-120% of the known value.
- 12.16 Dilution Test: The dilution test is performed whenever matrix spike or replicate criteria and post digestion spike criteria are exceeded. For sample concentrations that are sufficiently high (minimally, a factor of 25 times greater than the LOQ), the analysis of a fivefold (1+4) dilution must agree within  $\pm 20\%$  of the original determination. If the dilution test fails then a chemical or physical effect should be suspected. Corrective action can include additional dilution of the sample, the use of alternate methodologies, etc. or the data can be flagged and reported. The exact course of action will be dependent on the nature of the samples and project requirements and should be discussed with the project manager.
- 12.17 Instrument blanks should be evaluated for potential carryover and rinse times need to bring the analyte signal to within the CCB criteria. Results from instrument blanks run after standards or control samples should be used to establish levels at which carryover in samples may occur. Samples exhibiting similar effects of carryover should be reanalyzed.

### 13) Data Reduction and Reporting

#### 13.1 Calculations

13.1.1 Calculate sample results using the data system printouts and digestion information. The digestion and dilution information is entered into the data system. The data system then uses the calculations below to generate a sample result.

13.1.2 Aqueous samples are reported in  $\mu\text{g/L}$ :

$$\mu\text{g/L (Sample)} = C^* \times \text{Digestion Dilution Factor} \times \text{Post Digestion Dilution Factor.}$$

$C^*$ = Concentration of analyte as measured at the instrument in  $\mu\text{g/L}$  (in digestate).

13.1.3 Solid samples are reported in  $\text{mg/Kg}$ :

$$\text{mg/Kg (Sample)} = C^* \times \text{Post Digestion Dilution Factor} \times \frac{\text{Digestion Vol. (ml)}}{\text{Sample wt. (g)}} \times \frac{1\text{mg}}{1000\mu\text{g}} \times \frac{1\text{L}}{1000\text{ml}} \times \frac{1000\text{g}}{1\text{Kg}}$$

	STANDARD OPERATING PROCEDURE	Metals by ICP-MS (6020)
	ALS   Environmental – Kelso	MET-6020, Rev. 19.0
		Effective: 12/2/2020
		Page 14 of 22

C\*= Concentration of analyte as measured at the instrument in µg/L (in digestate).

NOTE: If results are to be reported on a dry weight basis, determine the dry weight of a separate aliquot of the sample, using the SOP for Total Solids.

13.2 Common isobaric interferences are corrected using equations equivalent to those listed in EPA Methods 6020B and 200.8. Monitoring of multiple isotopes for a single element provides a mechanism for identifying isobaric interferences. Refer to the Interferences section of EPA methods for additional descriptions of possible interferences and the mechanisms required for adequately compensating for their effects.

### 13.3 Data Review and Reporting

13.3.1 The ICP-MS operator reviews the MS data and signs and dates the Data Review Form. A qualified senior staff spectroscopist performs a secondary review of the data and the Data Review Form is signed and dated. The data is scanned for later compiling.

13.3.2 The data is saved on the local hard drive and is also copied to the appropriate directory on the network. The data directories are located at r:\icp\wip\data. The data is kept on the local directory for 1 month. The network files are periodically backed up on disc or network tape.

13.3.3 For “non-production” work (such as method development or research/development studies) the analyses are performed under the direction of a senior spectroscopist. All associated data is scrutinized by the senior spectroscopist. Original raw data and associated records are archived in the analytical project file.

13.3.4 The final review and approval of all data is performed by qualified spectroscopists.

## 14) Contingencies for Handling Out-of-Control or Unacceptable Data

14.1 Refer to the SOP for *Non Conformance and Corrective Action* for procedures for corrective action. Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

## 15) Method Performance

15.1 This method was validated through single laboratory studies of accuracy and precision. Refer to the reference method for additional method performance data available.

15.2 The method detection limit (MDL) is established using the procedure described in the SOP, *Performing Method Detection Limit Studies and Establishing Limits of Detection and Quantification*. Method Reporting Limits are established for this

	STANDARD OPERATING PROCEDURE	Metals by ICP-MS (6020)
	ALS   Environmental – Kelso	MET-6020, Rev. 19.0
		Effective: 12/2/2020
		Page 15 of 22

method based on MDL studies and as specified in the ALS Quality Assurance Manual.

## 16) Pollution Prevention and Waste Management

16.1 The laboratory will comply with all Federal, State and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.

## 17) Training

17.1 All analysts performing this analysis are required to read and understand this SOP.

17.2 Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

## 18) Method Modifications

18.1 There are no known modifications in this laboratory standard operating procedure from the reference method.

## 19) References

	STANDARD OPERATING PROCEDURE	Mercury in Liquid Waste
	ALS   Environmental – Kelso	MET-7470A, Rev. 20.0
		Effective: 2/05/2021
		SOP Review: 2/05/2021
		Page 2 of 12

## 1) Scope & Applicability

- 1.1 This procedure is used to determine the concentrations of Mercury in aqueous samples, including mobility-procedure extractions, aqueous wastes, and ground water, using EPA Method 7470A. Method 7470A is a cold-vapor atomic absorption procedure.
- 1.2 The Method Reporting Limit (MRL) is 0.2 µg/L. Equivalent nomenclature for MRL includes Estimated Quantitation Limit (EQL) and Practical Quantitation Limit (PQL). Therefore, MRL=EQL=PQL. The reported MRL may be adjusted if required for specific project requirements; however, the capability of achieving other reported MRLs must be demonstrated. The current MDL for 7470A is 0.02 µg/L. The MDL may change slightly as annual studies are performed.
- 1.3 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DOD ELAP. QC requirements defined in the SOP *Department of Defense Projects – Laboratory Practices and Project Management* (ADM-DOD5) may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 A representative aliquot of sample is prepared as described in this procedure. The mercury is reduced to its elemental state and aerated from solution and measured with an atomic absorption spectrometer. The mercury vapor passes through a cell positioned in the light path of the AA where absorbance is measured as a function of mercury concentration.

## 3) Definitions

- 3.1 For laboratory definitions applicable to most analyses, refer to the SOP for *Sample Batches*.

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. Final review and sign-off of the data is performed by the department supervisor/manager or designee.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency, as described in the SOP *Employee Training and Orientation* (ADM-TRAIN).

## 5) Interferences

- 5.1 Potassium permanganate is added to eliminate possible interference from sulfide. Samples high in chlorides require additional permanganate because, during the oxidation step, chlorides are converted to free chlorine, which absorbs radiation at 253 nm.

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.

## STANDARD OPERATING PROCEDURE

Mercury in Liquid Waste

MET-7470A, Rev. 20.0

Effective: 2/05/2021

SOP Review: 2/05/2021

Page 3 of 12

- 6.2 Sulfuric and Nitric Acid are used in this method. These acids are extremely corrosive and care must be taken while handling them. A face shield should be used while pouring acids. And safety glasses should be worn while working with the solutions. Lab coat and gloves should always be worn while working with these solutions.

### 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Aqueous samples are preserved with nitric acid (pH<2).  
7.2 The maximum holding time for mercury in aqueous samples is 28 days.

### 8) Standards, Reagents, and Consumable Materials

- 8.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Refer to the SOP *Reagent and Standards Login and Tracking (ADM-RLT)* for the complete procedure and documentation requirements.
- 8.2 All stocks, working solutions and sample dilutions should be prepared using deionized water (DI) conforming to ASTM Type I or ASTM Type II reagent water. For more information on reagent water generation, refer to the related SOP, Operation and Maintenance of Laboratory Reagent Water Systems.
- 8.3 Mercury stock solution (1,000 mg/L). Commercially prepared certified solution stored at room temperature. The expiration date determined by manufacturer.
- 8.4 Mercury intermediate stock solution (10 mg/L). Prepared from the stock solution listed above. Store at room temperature and assign a one month expiration date.
- 8.5 Mercury working standard (100 µg/L). Prepared from the intermediate stock solution listed above. Store at room temperature and prepare a new standard daily.
- 8.6 See the Procedures section for details on preparation of calibration and ICV standards. See the Quality Assurance section for QC sample preparation.
- 8.7 Reagent water - ASTM Type II water (laboratory deionized water).
- 8.8 Concentrated nitric and sulfuric acids. Purity of acids must be established by the laboratory as being high enough to eliminate the introduction of contamination above the Method Reporting Limit.
- 8.9 Potassium permanganate solution, 5% w/v. To prepare, add 50 g of solid reagent to 1000 mL of DI water and place on magnetic stir plate for approximately 30 minutes until dissolved.
- 8.10 Potassium persulfate solution, 5% w/v. To prepare, add 50g of solid reagent to 1000 mL of DI water and warm in water bath for approximately 10 minutes. Place the warmed solution on a magnetic stir plate for approximately 10 minutes until dissolved.
- 8.11 Sodium chloride/hydroxylamine hydrochloride solution, 12% w/v each. To prepare, add 120 g sodium chloride and 120 g of hydroxylamine hydrochloride to 1000 mL of DI water and place on magnetic stir plate for approximately 15 minutes until dissolved.
- 8.12 Stannous chloride, 10% w/v in HCl (7% v/v). To prepare, add 100 g stannous chloride crystals and 70 mL of concentrated hydrochloric acid in 1000 mL of DI water. Seal lid on mixing bottle and shake until the stannous chloride is dissolved.

### 9) Apparatus and Equipment

Mercury in Liquid Waste

MET-7470A, Rev. 20.0

Effective: 2/05/2021

SOP Review: 2/05/2021

Page 4 of 12

- 9.1 CETAC M-6100A Mercury Analyzer. (See Attachments for instrument parameters).
- 9.2 VWR Borosilicate glass tubes with disposable caps, 16 mL
- 9.3 Modified block digesters, 10 and 100 mL.
- 9.4 Pipettors, Eppendorf and Finnpiptette® fixed and adjustable volume.
- 9.5 Polypropylene graduated cylinders, 50 mL.
- 9.6 125 mL Centrifuge tubes.
- 9.7 Infrared Thermometer: Fluke: Model: 572-2.

## 10) Preventative Maintenance

- 10.1 All maintenance activities are recorded in a maintenance logbook kept for each instrument. Pertinent information (serial numbers, instrument I.D., etc.) must be in the logbook. This includes the routine maintenance described in section 9. The entry in the log must include: date of event, the initials of who performed the work, and a reference to analytical control.
- 10.2 ALS staff performs all routine maintenance and troubleshooting. Preventative maintenance activities listed below should be performed when needed as determined by instrument performance (i.e. stability, sensitivity, etc.) or by visual inspection. Repairs of an extraordinary nature may or may not require factory service, depending on the nature of the task.
- 10.3 Keep the instrument free of dust, deposits, and chemical spills.
- 10.4 Replace the peristaltic and autosampler rinse tubing.
- 10.5 Remove and clean the Gas-Liquid separator.
- 10.6 Remove, dismantle, and clean the optical cells (sample cell and reference cell) including the sapphire windows.
- 10.7 Replace the Hg lamp bulb when the Lamp Over-Range is triggered. (The new instrument does not display a value).
- 10.8 Each block digester is uniquely identified and the temperature is verified with each batch of samples. The temperature is turned to the 95°C setting and the block is allowed to come to temperature. The analyst will verify that the block gives a temperature of  $95 \pm 2^\circ\text{C}$  using a semi-annually-calibrated traceable handheld infrared thermometer. If not at the right temperature, the thermostat is adjusted until the IR thermometer reads  $95 \pm 2^\circ\text{C}$ .

## 11) Procedure

### 11.1 Sample Preparation

- 11.1.1 Shake the sample and measure 10 mL into a 16 mL glass tube. Add 0.5 mL of  $\text{H}_2\text{SO}_4$  and 0.25 mL of concentrated  $\text{HNO}_3$ , mixing after each addition. Add 1.5 mL of potassium permanganate solution to each tube and shake. If the purple color does not persist for 15 minutes add additional potassium permanganate until it does so. Any additional potassium permanganate solution must also be added to the blanks and standards in equal proportion. Note: Spiking solution is added prior to acidification.
- 11.1.2 Add 0.8 mL of potassium persulfate to each tube and heat for 2 hours in a block digester maintained at 95°C. Cool and add 0.6 mL of sodium chloride-hydroxylamine hydrochloride solution.

STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

Mercury in Liquid Waste

MET-7470A, Rev. 20.0

Effective: 2/05/2021

SOP Review: 2/05/2021

Page 5 of 12

11.1.3 The samples are now ready to be analyzed. The analyzer does the final step of adding the stannous chloride solution automatically.

11.2 Calibration

11.2.1 To prepare calibration standards a 10 ppm intermediate stock solution is first prepared by aliquoting 1.0 mL of commercially prepared 1000 ppm stock standard into an acid rinsed 100 mL Class A volumetric flask and diluting to volume with 1% HNO<sub>3</sub> (This solution must be prepared monthly). Next, a 100 ppb working solution is prepared by aliquoting 1.0 mL of the 10 ppm intermediate stock solution into an acid rinsed 100 mL Class A volumetric flask and diluting to volume with 1% HNO<sub>3</sub>. This solution must be prepared daily.

Note: All standard aliquots are measured using calibrated fixed or adjustable volume autopipettors.

11.2.2 Transfer 0, 0.1, 0.25, 0.5, 2.5, and 5.0 mL aliquots of the working solution to a series of labeled 125 mL centrifuge tubes. Add the appropriate amount of reagent water to bring each bottle to a final volume of 50 mL. The final concentrations of the prepared standards are 0, 0.2, 0.5, 1.0, 5.0, 10.0 ppb. Standards may be prepared at 100 mL final volume rather than 50 mL volume to ensure sufficient quantity is available for recalibrations as well as aliquoting for CCV, CCB and CRA samples in the analytical run. The proportions of reagents and their sources are identical to those of the samples.

11.2.3 The Initial Calibration Verification (ICV) is prepared by first making a 1000 ppb intermediate solution. 0.10 mL of commercially prepared 1000 ppm stock standard, from a different manufacturer and lot than the calibration standard, is aliquoted into an acid rinsed 100 mL Class A volumetric flask and diluting to volume with 1% HNO<sub>3</sub>. This solution must be prepared monthly. Prepare the ICV standard by aliquoting 0.25 mL to a labeled 125 mL centrifuge tube. Add 49.75 mL of reagent water to bring the final volume to 50 mL.

11.2.4 Mix thoroughly and add 2.5 mL of concentrated H<sub>2</sub>SO<sub>4</sub> and 1.25 mL of concentrated HNO<sub>3</sub> to each bottle. Add 7.5 mL of potassium permanganate to each bottle and let stand for 15 minutes. Add 4 mL of potassium persulfate to each bottle and heat in the modified block for 2 hours at 95°C. Cool and add 3 mL of sodium chloride-hydroxylamine hydrochloride solution.

11.3 CETAC Calibration and Sample Analysis

11.3.1 Turn on the CETAC instrument, including the Hg lamp, and autosampler. After this is done open the operating software (Mercury Analyzer 1.6.5).

11.3.2 The rinse station for the autosampler turns on automatically, but the peristaltic pump must be started manually. Make sure all sample uptake and drain tubes are placed correctly on the pump and are secured with the appropriate tension. Place the reagent uptake tube in the stannous chloride and start the pump.

11.3.3 From the software's main screen select "File", then: "New From". Under "Template Worksheet", click "Browse" and then select "Kelso Hg Template II". Enter the name of the worksheet and click: OK.

Note: The CETAC software will not allow "0" to be entered as a true value for a "Standard". The software template includes the "0" standard as the "calibration blank".

11.3.4 Go to the "Sequence Editor" tab to generate a sequence, then enter the QC and field samples to be analyzed in the appropriate order.

11.3.5 Transfer the solutions to be analyzed to labeled 12 mL polyethylene test tubes and place them in the appropriate spaces on the autosampler trays.

STANDARD OPERATING PROCEDURE ALS   Environmental – Kelso	Mercury in Liquid Waste
	MET-7470A, Rev. 20.0
	Effective: 2/05/2021
	SOP Review: 2/05/2021
	Page 6 of 12

11.3.6 Transfer the calibration blank and standards (0.2, 0.5, 1.0, 5.0, and 10 ppb) from their Centrifuge tubes to the standard tubes located behind the autosampler trays. The calibration blank is placed in the left most tube and the other standards are placed in ascending order to the right.

11.3.7 Click start and the analysis will begin.

11.3.8 After the calibration standards have run the software will use linear regression to create a calibration curve based on the concentration and measured absorbance of each standard. The form of regression line is  $y = mx + b$ . If the correlation coefficient of the curve is greater than 0.995 the analysis will continue, if not the analysis will be terminated and corrective action will be needed by the analyst.

11.4 As the analysis sequence proceeds, next analyze the following QC standards.

- ICV (5.0 ppb standard prepared from a second source)
- ICB
- CRA (0.2 ppb calibration standard)
- CCV (5.0 ppb calibration standard)
- CCB

11.5 If either the ICV or CCV are different from their true values by more than 10% the software will terminate the analysis. If either the ICB or CCB is greater than the MRL of 0.2 µg/L the software will terminate the analysis. CRA limits are ±30%.

**Note:** For projects falling under DoD QSM requirements, the QSM criteria for CRA standards is ±20% and for ICB and CCB standards no analytes detected > LOD.

11.6 Sample Analysis

11.6.1 The samples are analyzed with the CETAC analyzer in the same manner as the calibration standards. The analyzer does the step of adding the stannous chloride solution automatically. Check the baseline between samples to verify that the spectrometer reading has stabilized at the normal baseline level.

11.6.2 The analytical sequence should be set up to include all samples, QC samples, blanks, and calibration verification standards at necessary intervals. Refer to the SOP for Sample Batches.

11.7 Sample digestion batches are analyzed with a set of CCV and CCB standards which are run at the beginning and end of the analytical run and at a minimum every 10 samples during the run. The same criteria listed above are applied to the CCVs and CCBs. If outside these limits the analysis is terminated.

## 12) QA/QC Requirements

12.1 Initial Precision and Recovery Validation

12.1.1 The accuracy and precision of the procedure must be validated before analyses of samples begin, or whenever significant changes to the procedures have been made. To do this, four water samples are spiked with the LCS spike solution, then prepared and analyzed.

12.2 Method Detection Limits

12.2.1 A method detection limit (MDL) study must be undertaken before analysis of samples can begin. To establish detection limits that are precise and accurate, the analyst must perform the following procedure. Spike a minimum of seven blank replicates with a MDL spiking solution near the MRL and analyze. Refer to *Performing and Documenting Method*

STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

Mercury in Liquid Waste

MET-7470A, Rev. 20.0

Effective: 2/05/2021

SOP Review: 2/05/2021

Page 7 of 12

*Detection Limit Studies and Establishing Limits of Detection and Quantification (CE-QA011/ADM-MDL). The MDL study must be verified annually.*

12.2.2 Calculate the average concentration found ( $\bar{x}$ ) in  $\mu\text{g/L}$ , and the standard deviation of the concentrations ( $s$ ) in  $\mu\text{g/L}$  for each analyte. Calculate the MDL for each analyte. Refer to ADM-MDL). The MDL study must be verified annually with a limit of detection (LOD).

12.2.3 Note: Method Detection Limits are subject to change as new MDL studies are completed.

12.3 Limits of Quantification (LOQ)

12.3.1 The laboratory establishes a LOQ for each analyte as the lowest reliable laboratory reporting concentration or in most cases the lowest point in the calibration curve which is less than or equal to the desired regulatory action levels, based on the stated project requirements. Analysis of a standard or extract prepared at the lowest point calibration standard provides confirmation of the established sensitivity of the method. The LOQ recoveries should be within 50-150 % of the true values to verify the data reporting limit. Refer to the SOP: Performing and Documenting Method Detection Limit Studies and Establishing Limits of Detection and Quantification (CE-QA011)/ADM-MDL).

12.4 Ongoing QC Samples required are described in the ALS-Kelso Quality Assurance Manual, and in SOP *Sample Batches* (ADM-BATCH). For this analysis, these include:

12.4.1 Prepare one method blank (MB) per digestion batch, or per 20 samples, or per EPA SDG group, whichever is more frequent. Use D.I. water and follow the digestion procedures. The Method Blank should be  $< \text{MRL}$ . Re-digest the associated samples if sample levels are  $< 20\text{X}$  MB level.

12.4.2 DoD QSM Method Blank Requirements - The Method Blank will be considered contaminated if:

12.4.2.1 The concentration of any common laboratory contaminant in the blank exceeds the reporting limit and is greater than  $1/10$  the amount measured in any sample or  $1/10$  the regulatory limit (whichever is greater).

12.4.2.2 The blank result otherwise affects the samples results as per the test method requirements or the project-specific objectives.

12.4.3 Prepare one duplicate and matrix spike sample per each digestion batch, or per twenty samples, or per EPA SDG group, whichever is more frequent. At times, specific samples will be assigned as duplicates or spikes depending on client requirements. The matrix spike is prepared by aliquoting 0.05 mL of the 1000 ppb working standard to the 10 mL sample designated as the matrix spike, resulting in a spike concentration of 5ppb.

**Note:** Duplicate samples are routinely analyzed, however all DoD projects require a MSD with every preparation batch. The MSD sample is prepared as described above.

12.4.3.1 The RPD criterion for duplicates is 20% RPD. If not, flag the data or re-digest samples. Apply Matrix spike recovery criterion listed in the DQO Table, unless project-specific limits are required. For DoD QSM work, MS recoveries are assessed using the QSM LCS control limits. If the MS (and/or MSD where applicable) recovery is outside acceptance limits proceed with the additional interference tests. Based on results of these tests, the physical nature of the sample (e.g. homogeneity), and any specific project requirements, a determination can then be made as to appropriate corrective action (e.g. re-digestion, reporting with a qualifier, alternative methodologies, etc.). If the analyte concentration is  $>4\text{x}$  the spike level the spike control limit is no longer applicable and no action is required.

STANDARD OPERATING PROCEDURE ALS   Environmental – Kelso	Mercury in Liquid Waste
	MET-7470A, Rev. 20.0
	Effective: 2/05/2021
	SOP Review: 2/05/2021
	Page 8 of 12

12.4.4 Prepare one Laboratory Control Sample (LCS) per digestion batch, or per 20 samples. The LCSW is prepared by aliquoting 0.05 mL of the 1000 ppb ICV intermediate solution to 10 mL of reagent water, resulting in a concentration of 5ppb, and processing as per the procedure.

12.4.4.1 Apply LCS recovery criteria listed in the DQO Table, unless project-specific limits are required. If the LCS fails the acceptance criteria, re-digest the batch of samples. An LCS recovery criterion for **DoD** QSM projects is 80-120%.

12.4.4.2 Calculate the LCS recovery as follows:

$$\%R = X/TV \times 100$$

Where X = Concentration of the analyte recovered  
TV = True value of amount spiked

12.4.5 Interference Tests: Prepare one post spike for every batch of samples and if samples are sufficiently high (10x the MRL/LOQ) a serial dilution. The serial dilution must agree within 10% of the original sample result. Post spike recovery acceptance limits for method 7470A are 85-115% under SW846 Update 3, and 80-120% for project falling under SW846 Update 4. When both the post spike and dilution tests fail all of the samples in the associated preparation batch must be quantified via Method of Standard Additions (MSA).

### 13) Data Reduction and Reporting

13.1 Solution concentrations are calculated by the Mercury Analyzer software based on the linear regression calibration curve created when the calibration standards are analyzed. The absorbance measured for each sample is applied to the linear regression curve and the final solution concentration is determined and displayed as the instrument result.

13.2 Calculate sample results using the data system printouts and digestion information. The digestion and dilution information is entered into the data system. The data system then uses the calculations below to generate a sample result.

13.2.1 Aqueous samples are reported in µg/L:

$$\mu\text{g} / \text{L} (\text{Sample}) = C^* \times \text{Digestion Dilution Factor} \times \text{Post Digestion Dilution Factor}$$

C\* = Concentration of analyte as measured at the instrument in mg/L (in digestate).

13.3 A daily run log of all samples analyzed is maintained. All CLP data should be printed and stored after operator has checked for evenness of burns. A copy of this document will go with each package of Tier III or higher data run that day.

13.4 It is the analyst's responsibility to review analytical data to ensure that all quality control requirements have been met for each analytical run. Results for QC analyses are calculated and recorded.

13.5 Record all sample volumes and dilutions on an A.A. benchsheet.

13.6 Record all concentrations determined at the instrument and calculate the final results in µg/L. Record the final results on the A.A. benchsheet.

13.7 The data packet for the sequence is submitted for review by supervisor or designee. The results are transferred to the appropriate report form located in the ALS network directory R:\ICP\WIP. Once the results are transferred, the report is reviewed.

STANDARD OPERATING PROCEDURE

ALS | Environmental – Kelso

Mercury in Liquid Waste

MET-7470A, Rev. 20.0

Effective: 2/05/2021

SOP Review: 2/05/2021

Page 9 of 12

- 13.8 Refer to the *SOP for Laboratory Data Review Process* (ADM-DREV) for general instructions for data review.
- 13.9 Following primary data interpretation and calculations, all data is reviewed by a secondary analyst. Following generation of the report, the report is also reviewed. Refer to the *SOP for Laboratory Data Review Process* (ADM-DREV) for details. The person responsible for final review of the data report and/or data package should assess the overall validity and quality of the results and provide any appropriate comments and information to the Project Manager to inclusion in the report narrative.

#### 14) Contingencies for Handling Out-of-Control or Unacceptable Data

- 14.1 Refer to the *SOP for Nonconformance and Corrective Action Procedures* (ADM-NCAR) for procedures for corrective action.
- 14.2 Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

#### 15) Method Performance

- 15.1 This method was validated through single laboratory studies of accuracy and precision. Refer to the reference method for additional available method performance data.
- 15.2 The method detection limit (MDL), limit of detection (LOD), and limit of quantitation (LOQ) are established using the procedure described in *Performing and Documenting Method Detection Limit Studies and Establishing Limits of Detection and Quantitation*. Method Reporting Limits are established for this method based on MDL studies and as specified in the ALS Quality Assurance Manual.

#### 16) Pollution Prevention and Waste Management

- 16.1 The laboratory will comply with all Federal, State and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.
- 16.2 This method uses acid/bases. Waste acid/base is hazardous to the sewer system and to the environment. All waste must be neutralized prior to disposal down the drain. The neutralization step is considered hazardous waste treatment and must be documented on the treatment by generator record. Refer to the ALS Lab Waste Management Plan.

#### 17) Training

- 17.1 All analysts performing this analysis are required to read and understand this SOP.
- 17.2 Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

#### 18) Method Modifications

- 18.1 There are no known modifications in this laboratory standard operating procedure from the reference method.

#### 19) References

- 19.1 DoD Quality Systems Manual for Environmental Laboratories Current Version.
- 19.2 TNI Quality Standards, 2009; 2016.

## 20) Changes since Last Revision

Revision Number	Effective Date	SOP Review	Document Editor	Description of Changes
20.0	2/05/2021		T.Caron	ADMIN changes: SOP signatories, updates to standard paragraphs; References. Section 9: Infrared Thermometer: Fluke Model: 572 has been added to the equipment list. Section 10.8: Added Block digester temperature verification procedure. Section: 11.1.2: Procedural step has been updated to reflect current practice.
		Keith Linn		Procedural change form and revision request dated 1/27/2021.

## 21) Attachments, Tables, and Appendices

- 21.1 Attachment 1: Instrument Parameters.
- 21.2 Table 1: Summary of Corrective Actions.

## Attachment 1 Instrument Parameters

### Analysis Parameters

Instrument M-6100 Mercury Analyzer

#### Conditions

Gas flow (mL/min)	Sample Uptake (s)	Rinse (s)	Read delay (s)	Replicates (#)	Replicate time (s)	Pump speed (%)	Wavelength (nm)
40	30.00	60.00	50.00	4	2.00		253.65

#### Instrumental Zero

Zero before first sample: No

Zero periodically: Yes  
Before each calibration.

#### Baseline Correction

#1 Start time (s)	#1 End time (s)	#2 Start time (s)	#2 End time (s)
5.00	10.00		

#### Standby Mode

Enabled: Yes  
Standby Options: gas off, lamp off

#### Autodilution

Enabled: No  
Condition:  
Tube # range:  
If no autodilution tubes remaining

### Calibration

#### Settings

Algorithm	Through blank	Weighted fit	Cal. Type	Recalibration rate	Reslope rate	Reslope standard
Linear	Yes	No	Normal	0	0	N/A

#### Limits

Calibration slope		Reslope		Coeff. of Determination
Lower (%)	Upper (%)	Lower (%)	Upper (%)	
75	125	75	125	0.99500

Error action: Stop analysis

### QC

GLP Override: Yes

### QC Tests

**Table 1**

<b>Summary of Corrective Actions</b>				
<b>Method Reference</b>	<b>Control</b>	<b>Specification and Frequency</b>	<b>Acceptance Criteria</b>	<b>Corrective Action</b>
EPA 7470A	ICAL	Prior to sample analysis	$R2 \geq 0.995$	Correct problem then repeat ICAL
EPA 7470A	ICV	After ICAL	$\pm 10\%$	Correct problem and verify second source standard; rerun second source verification. If fails, correct problem and repeat initial calibration.
EPA 7470A	CCV	Prior to sample analysis	$\pm 10\%$	Correct problem then repeat CCV or repeat ICAL
EPA 7470A	Method Blank	Include with each analysis batch (up to 20 samples)	<MRL	If target exceeds MRL, reanalyze to determine if instrument was cause. If still noncompliant then:  Re-extract or reanalyze samples containing contaminate, unless samples contain > 20x amount in blank.
EPA 7470A	Laboratory Control Sample	Include with each analysis batch (up to 20 samples)	See DQO Table	If exceeds limits, re-extract and re-analyze
EPA 7470A	Matrix Spike	Include with each analysis batch (up to 20 samples)	See DQO Table	Evaluate data to determine if there is a matrix effect or analytical error
EPA 7470A	Sample Duplicates	Include with each analysis batch (up to 20 samples)	$RPD \leq 20$	Re-homogenize and re-analyze if result is > 5 X the MRL

## Mercury in Solid or Semi-Solid Waste

DOCUMENT ID: MET-7471, REV 21.0

Approved By:   
Inorganics Manager, Jeff Coronado

Date: 12/1/20

Approved By:   
Quality Assurance Manager, Kurt Clarkson

Date: 12/1/2020

Approved By:   
Laboratory Director, Charles (Pat) Byrne

Date: 12-1-20

## 1) Scope & Applicability

- 1.1 This Standard Operating Procedure (SOP) describes the procedure used to determine the concentrations of Mercury in soils, sediments, freeze dried tissues, bottom deposits, and sludge-type materials using Method EPA 7471A or 7471B. If this dissolution procedure is not sufficient to dissolve a specific matrix type or sample, then this method is not applicable for that matrix. Method 7471 is a cold-vapor atomic absorption procedure.
- 1.2 The Method Reporting Limit (MRL) is 0.02 mg/kg. Equivalent nomenclature for MRL includes Estimated Quantitation Limit (EQL). Therefore, MRL=EQL. The reported MRL may be adjusted if required for specific project requirements; however, the capability of achieving other reported MRLs must be demonstrated. A Method Detection Limit (MDL) of 0.002 mg/kg has been achieved using this procedure. Refer to the ALS Kelso DQO Table for current data quality objectives.
- 1.3 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DOD ELAP. QC requirements defined in the SOP *Department of Defense Projects – Laboratory Practices and Project Management (ADM-DOD/ADM-DOD5)* may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 A representative aliquot of sample is prepared as described in this procedure. The mercury is reduced to its elemental state and aerated from solution and measured with an atomic absorption spectrometer. The mercury vapor passes through a cell positioned in the light path of the AA where absorbance is measured as a function of mercury concentration.

## 3) Definitions

- 3.1 For general definitions applicable to most analyses refer to the SOP for *Sample Batches*, ADM-BATCH.

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. The department supervisor/manager or designee performs final review and sign-off of the data.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency, as described in the SOP *Employee Training and Orientation* (ADM-TRAIN).

## 5) Interferences

- 5.1 Potassium permanganate is added to eliminate possible interference from sulfide. Samples high in chlorides require additional permanganate because, during the oxidation step, chlorides are converted to free chlorine, which absorbs radiation at 253 nm.

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Kelso Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.
- 6.2 Hydrochloric and/or Nitric Acid are used in this method. These acids are extremely corrosive and care must be taken while handling them. A face shield should be used while pouring acids. And safety glasses should be worn while working with the solutions. Lab coat and gloves should always be worn while working with these solutions.

## 7) Sample Collection, Containers, Preservation, and Storage

- 7.1 Glass, plastic, and polytetrafluoroethylene (PTFE) containers are suitable in most cases.
- 7.2 Non-aqueous samples are stored at  $4 \pm 2$  °C from receipt until analysis, unless otherwise dictated by project specifications.
- 7.3 Samples must be analyzed within 28 days of sampling.
- 7.4 Non-aqueous samples are stored at  $4 \pm 2$  °C from receipt until analysis, unless otherwise dictated by project specifications.

## 8) Apparatus and Equipment

- 8.1 CETAC M-6100A Mercury Analyzer. See Attachments, Tables and Appendices for instrument parameters.
- 8.2 Environmental Express Block Digestion Unit.
- 8.3 Pipettors, Eppendorf and Finn pipette fixed and adjustable volume.
- 8.4 Polypropylene graduated cylinders, 50 mL.
- 8.5 125 mL Digestion Vessel tubes.
- 8.6 Laboratory balance, top-loader capable of readings .001g (3-place). Mettler, Ohaus, or equivalent Standards.
- 8.7 Infrared Thermometer.

## 9) Standards, Reagents, and Consumable Materials

- 9.1 Reagent grade chemicals shall be used in all tests. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lowering the accuracy of the determination. The preparation for all laboratory prepared reagents and solutions must be documented in a laboratory logbook. Standards, reagents and consumable material documentation shall indicate traceability to purchased reagents or compounds. Refer to the SOP *Reagent/Standards Login and Tracking* (ADM-RTL) for the complete procedure and documentation requirements.
- 9.2 All stocks, working solutions and sample dilutions should be prepared using deionized water (DI) conforming to ASTM Type I or ASTM Type II reagent water. For more information on reagent water generation, refer to the related SOP, Operation and Maintenance of Laboratory Reagent Water Systems.
- 9.3 Mercury stock solution (1,000 mg/L). Commercially prepared certified solution stored at room temperature. The expiration date determined by manufacturer.

- 9.4 Mercury working standard (100µg/L). Prepared from the intermediate stock solution listed above. Store at room temperature and prepare a new standard daily.
- 9.5 Laboratory Control Sample - ERA Priority Pollutant/CLP Inorganic Soil reference material. Store at room temperature in the original container and use the vendor expiration date.
- 9.6 Matrix spike solution (1 mg/L) - Prepare by making a 1:1000 dilution of the mercury stock solution. Store at room temperature and prepare a new standard monthly.
- Note:** See the Procedure section for details on preparation of calibration and ICV standards. See the Quality Assurance section for QC sample preparation.
- 9.7 Reagent water - ASTM Type II water (laboratory deionized water).
- 9.8 Acids - Purity of acids must be established by the laboratory as being high enough to eliminate the introduction of contamination above the Method Reporting Limit.
- 9.8.1 Nitric Acid (HNO<sub>3</sub>) 69-70% - JT Baker-Baker Instra-Analyzed® or equivalent.
- 9.8.2 Sulfuric Acid concentrated (H<sub>2</sub>SO<sub>4</sub>) - EMD-OmniTrace® or equivalent.
- 9.8.3 Hydrochloric Acid concentrated (HCL) - VWR - BHD-Aristar® or equivalent.
- 9.9 Potassium permanganate solution, 5% w/v. To prepare, add 50 g of solid reagent to 1000 mL of DI water and place on magnetic stir plate for approximately 30 minutes until dissolved.
- 9.10 Sodium chloride/hydroxylamine hydrochloride solution, 12% w/v each. To prepare, add 120 g sodium chloride and 120 g of hydroxylamine hydrochloride to 1000 mL of DI water and place on magnetic stir plate for approximately 15 minutes until dissolved.
- 9.11 Stannous chloride, 10% w/v in HCl (7% v/v). To prepare, add 100 g stannous chloride crystals and 70 mL of concentrated hydrochloric acid in 1000 mL of D.I. water. Seal lid on mixing bottle and shake until the stannous chloride is dissolved.
- 9.12 Aqua Regia - Prepare immediately before use by carefully adding 3 parts of concentrated HCL to one part of HNO<sub>3</sub>.

## 10) Preventative Maintenance

- 10.1 All maintenance activities are recorded in a maintenance logbook kept for each instrument. Pertinent information (serial numbers, instrument I.D., etc.) must be in the logbook. This includes the routine maintenance described in section 9. The entry in the log must include: date of event, the initials of who performed the work, and a reference to analytical control.
- 10.2 ALS staff performs all routine maintenance and troubleshooting. Preventative maintenance activities listed below should be performed when needed as determined by instrument performance (i.e. stability, sensitivity, etc.) or by visual inspection. Repairs of an extraordinary nature may or may not require factory service, depending on the nature of the task.
- 10.3 Keep the instrument free of dust, deposits, and chemical spills.
- 10.4 Replace the peristaltic and autosampler rinse tubing.
- 10.5 Remove and clean the Gas-Liquid separator.
- 10.6 Remove, dismantle, and clean the optical cells (sample cell and reference cell) including the sapphire windows.

- 10.7 Replace the Hg lamp bulb when the Lamp Over-Range is triggered. (The new instrument does not display a value).
- 10.8 Each block digester is uniquely identified and the temperature is verified with each batch of samples. The temperature is turned to the 95°C setting and the block is allowed to come to temperature. The analyst will verify that the block gives a temperature of  $95 \pm 2^\circ\text{C}$  using a semi-annually-calibrated traceable handheld infrared thermometer. If not at the right temperature, the thermostat is adjusted until the IR thermometer reads  $95 \pm 2^\circ\text{C}$ .

## 11) Procedure

### 11.1 Sample Preparation

- 11.1.1 Mix the sample thoroughly to achieve homogeneity. For soil, sediment, solids, weigh approximately 0.5 g of well-homogenized sample and place in the bottom of a 125 mL digestion tube and record the weight to the nearest 0.01g. Add 5.0 mL of reagent water and 5.0 mL of aqua regia, then heat in the Block Digestion Unit for 2 minutes at 95°C.
- 11.1.2 Cool then add 10 mL of reagent water and 15 mL of potassium permanganate solution. If the purple color does not persist for 15 minutes, add additional potassium permanganate until it does so. Any additional potassium permanganate solution must also be added to the blanks and standards in equal proportion.  
**Note:** Spiking solution is added prior to acidification.
- 11.1.3 Mix thoroughly and place in the heating block for 30 minutes at 95°C. The temperature of the block is monitored with a thermometer that is calibrated annually.
- 11.1.4 Cool and add 6 mL of sodium chloride-hydroxylamine hydrochloride to reduce the excess permanganate. Perform this addition under a hood as  $\text{Cl}_2$  could be evolved.
- 11.1.5 Add 27 mL of reagent water and the sample is ready for analysis. (The vapor generator does the step of adding the stannous chloride solution automatically.)

### 11.2 Calibration

- 11.2.1 To prepare calibration standards a 10 ppm intermediate stock solution is first prepared by aliquoting 1.0 mL of commercially prepared 1000 ppm stock standard into an acid rinsed 100 mL Class A volumetric flask and diluting to volume with 1%  $\text{HNO}_3$ . This solution must be prepared monthly. Next, a 100 ppb working solution is prepared by aliquoting 1.0 mL of the 10 ppm intermediate stock solution into an acid rinsed 100 mL Class A volumetric flask and diluting to volume with 1%  $\text{HNO}_3$ . This solution must be prepared daily.  
**Note:** All standard aliquots are measured using calibrated fixed or adjustable volume autopipettors or calibrated disposable 5.0 or 10.0 mL pipettes.
- 11.2.2 Transfer 0, 0.1, 0.25, 0.5, 2.5 and 5.0 mL aliquots of the working solution to a series of labeled 125 mL digestion tubes. Add the appropriate amount of reagent water to bring each bottle to a volume of 5mL. Add 5.0 mL of aqua regia and heat in the heating block for 2 minutes at 95°C. The final concentrations of the prepared standards are 0, 0.2, 0.5, 1.0, 5.0, 10.0 ppb.

- 11.2.3 The Initial Calibration Verification (ICV) is prepared by first making a 1000 ppb intermediate solution. 0.10 mL of commercially prepared 1000 ppm stock standard, from a different manufacturer and lot than the calibration standard, is aliquoted into an acid rinsed 100 mL Class A volumetric flask and diluting to volume with 1% HNO<sub>3</sub>. This solution must be prepared monthly. Prepare the ICV standard by aliquoting 0.25 mL to a labeled 125 mL digestion tube. Add the 4.75 mL of reagent water and 5.0 mL of Aqua Regia.
- 11.2.4 Cool and then add 10 mL of reagent water and 15 mL of potassium permanganate solution and return the tubes to the Block Digestion Unit for 30 minutes.
- 11.2.5 Cool and add 6.0 mL of sodium chloride-hydroxylamine hydrochloride solution. Add 27 mL of reagent water and the standards are ready for analysis.
- 11.2.6 CETAC Calibration and Sample Analysis
- 11.2.6.1 Turn on the CETAC instrument, including the Hg lamp, and autosampler. After this is done turn open the operating software (Mercury Analyzer 1.6.5).
- 11.2.6.2 The rinse station for the autosampler turns on automatically, but the peristaltic pump must be started manually. Make sure all sample uptake and drain tubes are placed correctly on the pump and are secured with the appropriate tension. Place the reagent uptake tube in the stannous chloride and start the pump.
- 11.2.6.3 From the software's main screen select "File", then: "New From". Under "Template Worksheet", click "Browse" and then select "Kelso Hg Template II". Enter the name of the worksheet and click: OK.
- 11.2.6.4 Go to the "Sequence Editor" tab to generate a sequence, then enter the QC and field samples to be analyzed in the appropriate order.
- 11.2.6.5 Transfer the solutions to be analyzed to labeled 12mL polyethylene test tubes and place them in the appropriate spaces on the autosampler trays.
- 11.2.6.6 Transfer the calibration blank and standards (0.2, 0.5, 1.0, 5.0, and 10 ppb) from their digestion tubes to the standard tubes located behind the autosampler trays. The calibration blank is placed in the left most tube and the other standards are placed in ascending order to the right.
- 11.2.6.7 Click start and the analysis will begin.
- 11.2.6.8 After the calibration standards have run the software will use linear regression to create a calibration curve based on the concentration and measured absorbance of each standard. The form of regression line is  $y = mx + b$ . If the correlation coefficient of the curve is greater than 0.995 the analysis will continue, if not the analysis will be terminated and corrective action will be needed by the analyst.
- 11.3 As the analysis sequence proceeds, next analyze the following QC standards.
- ICV (5.0 ppb standard prepared from a second source)
  - ICB
  - CRA (0.2 ppb calibration standard)
  - CCV (5.0 ppb calibration standard)
  - CCB

11.3.1 If either the ICV or CCV are different from their true values by more than 10% the software will terminate the analysis. If either the ICB or CCB is greater than the MRL the software will terminate the analysis. Method 7471A does not contain criteria for the CRA, however, the result must be a positive measured concentration. For 7471B analyses the criteria are  $\pm 30\%$  of the true value. Also, specific project requirements may apply.

**Note:** For projects falling under DoD QSM requirements, the QSM criteria for CRA standards is  $\pm 20\%$  and for ICB and CCB standards no analytes detected > LOD. (The ICV limit is as listed above.)

#### 11.4 Sample Analysis

11.4.1 The samples are analyzed with the CETAC analyzer in the same manner as the calibration standards. The analyzer does the step of adding the stannous chloride solution automatically. Check the baseline between samples to verify that the spectrometer reading has stabilized at the normal baseline level.

11.4.2 The analytical sequence should be set up to include all samples, QC samples, blanks, and calibration verification standards at necessary intervals. Refer to the SOP for Sample Batches.

11.5 Sample digestion batches are analyzed with a set of CCV and CCB standards which are run at the beginning and end of the analytical run and at a minimum every 10 samples during the run. The same criteria listed above are applied to the CCVs and CCBs and if one is found to be outside these limits the analysis is terminated.

## 12) QA/QC Requirements

### 12.1 Initial Precision and Recovery Validation

12.1.1 This method shall operate under the formal Quality Assurance Program established at ALS and must maintain records that define the quality of data that is generated. Data shall be compared to established criteria in order to determine if the results of the analyses meet the performance characteristics of the method. It is required that an initial demonstration of capability and periodic analysis of laboratory reagent blanks, laboratory fortified blanks, and other QC solutions as a continuing check on performance. The accuracy and precision of the procedure must be validated *before* analyses of samples begin, or whenever significant changes to the procedures have been made.

12.1.2 Initial demonstration of capability must be performed by each analyst performing sample analysis and documented in the laboratory records.

### 12.2 Method Detection Limits

12.2.1 A method detection limit (MDL) study must be undertaken before analysis of samples can begin. To establish detection limits that are precise and accurate, the analyst must perform the following procedure. Spike a minimum of seven blank replicates with a MDL spiking solution near the MRL and analyze. Refer to *Performing and Documenting Method Detection Limit Studies and Establishing Limits of Detection and Quantification*.

12.2.2 Calculate the average concentration found ( $\bar{x}$ ) in  $\mu\text{g/L}$ , and the standard deviation of the concentrations ( $s$ ) in  $\mu\text{g/L}$  for each analyte. Calculate the MDL for each analyte. Refer to ADM-MDL.

**Note:** Method Detection Limits are subject to change as new MDL studies are completed.

12.3 Limits of Quantification

12.3.1 The laboratory establishes a Limit of Quantitation (LOQ) for each analyte as the lowest reliable laboratory reporting concentration or in most cases the lowest point in the calibration curve which is less than or equal to the desired regulatory action levels, based on the stated project requirements. Analysis of a standard or extract prepared at the lowest point calibration standard provides confirmation of the established sensitivity of the method. The LOQ recoveries should be within 70-130% of the true values to verify the data reporting limit. Refer to ADM-MDL.

12.4 For method 7471B, an LLQC sample (a CRA that is carried through the digestion) must be analyzed to verify accuracy at the MRL. The recovery must be  $\pm 30\%$ .

12.5 Ongoing QC Samples required are described in the ALS-Kelso Quality Assurance Manual, in *Sample Batches* (ADM-BATCH). For this analysis, these include:

12.5.1 Prepare one method blank (MB) per digestion batch, or per 20 samples, or per EPA SDG group, whichever is more frequent. Use D.I. water and follow the digestion procedures. The Method Blank should be  $< \text{MRL}$ . Re-digest the associated samples if sample levels are  $< 20\text{X}$  MB level.

**Note:** For projects falling under DoD QSM requirements, the QSM criteria for method blanks is no analytes detected  $> \frac{1}{2}$  MRL.

12.5.2 Prepare one Laboratory Control Sample (LCS) per digestion batch, or per 20 samples. Weigh 0.25 g of the current lot of "Environmental Resource Associates Priority Pollutant/CLP Inorganic Soil" prepared reference material in to a 125 mL Digestion vessel tube and prepare as per the procedure.

12.5.3 Calculate the LCS recovery as follows:

$$\%R = X/TV \times 100$$

Where

X = Concentration of the analyte recovered  
TV = True value of amount spiked

Apply LCS recovery criteria from the DQO Table, unless project-specific or in-house limits are established. For method 7471B, the LCS recovery limits are 80-120%. If statistical in-house limits are used, they must fall within the 80-120% range.

**Note:** For DoD QSM projects, the QSM LCS criterion is 80-120%. If the LCS fails the acceptance criteria, re-digest the batch of samples.

12.5.4 Prepare one sample duplicate and one matrix spike sample per each digestion batch, or per twenty samples, whichever is more frequent. For the matrix spike, add 0.25mL of the matrix spike solution to the designated spike sample, resulting in a spike concentration of 0.5 mg/kg. At times, specific samples will be assigned as duplicates or spikes depending on client requirements.

**Note:** Duplicate samples are routinely analyzed; however some projects may require a MSD. All DOD projects require a MSD. The MSD sample is prepared as described above.

12.5.5 The RPD criterion for duplicates is 20%. If not, flag the data or re-digest samples. Apply matrix spike recovery criterion listed in the DQO Table, unless

project-specific limits are required. For method 7471B, the recovery limits are 80-120%. If statistical in-house limits are used, they must fall within the 80-120% range. For DoD QSM work, MS recoveries are assessed using the QSM LCS control limits. If the MS (and/or MSD where applicable) recovery is outside acceptance limits proceed with the additional interference tests. Based on results of these tests, the physical nature of the sample (e.g. homogeneity), and any specific project requirements, a determination can then be made as to appropriate corrective action (e.g. re-digestion, reporting with a qualifier, alternative methodologies, etc.). If the analyte concentration is >4x the spike level the spike control limit is no longer applicable and no action is required.

**Note:** For DoD QSM projects, the duplicate RPD limit is 20% and MS recoveries are assessed using the QSM LCS control limits 80-120%.

12.5.5.1 Calculate percent recovery (%R) as:

$$\%R = \frac{X - X1}{TV} \times 100$$

Where X = Concentration of the analyte recovered  
X1 = Concentration of unspiked analyte  
TV = True value of amount spiked

12.5.5.2 Calculate Relative Percent Difference (RPD) as:

$$\%RPD = \frac{|R1 - R2|}{(R1 + R2) / 2} \times 100$$

Where R1 = Higher Result  
R2 = Lower Result

12.5.6 Interference Tests: Prepare one post spike for every batch of samples and if samples are sufficiently high (10x the MRL/LOQ) a serial dilution. The serial dilution must agree within 10% of the original sample result. Post spike recovery acceptance limits for method 7471A and 7471B are 80-120% for project falling under SW-846 Update IV. When both the post spike and dilution tests fail all of the samples in the associated preparation batch must be quantified via Method of Standard Additions (MSA).

### 13) Data Reduction and Reporting

- 13.1 It is the analyst's responsibility to review analytical data to ensure that all quality control requirements have been met for each analytical run. Results for QC analyses are calculated and recorded as specified in section 12.
- 13.2 Record all sample weight, volumes and dilutions on an A.A. benchsheet (see Attachments).
- 13.3 Solution concentrations are calculated by the Mercury Analyzer software based on the linear regression calibration curve created when the calibration standards are analyzed. The absorbance measured for each sample is applied to the linear regression curve and the final solution concentration is determined and displayed as the instrument result.
- 13.4 Calculate sample results using the data system printouts and digestion information. The digestion and dilution information is entered into the data system. The data

system then uses the calculations below to generate a sample result. Solid samples are reported in mg/Kg:

$$\text{mg/Kg(Sample)} = C^* \times \text{PostDigestionDilutionFactor} \times \frac{\text{DigestionVol.(ml)}}{\text{Samplewt.(g)}} \times \frac{1\text{mg}}{1000\text{ug}} \times \frac{1\text{L}}{1000\text{ml}} \times \frac{1000\text{g}}{1\text{Kg}}$$

C\*= Concentration of analyte as measured at the instrument in ug/L (in digestate).

**NOTE:** If results are to be reported on a dry weight basis as required by certain projects, the Sample Wt. (g) component of the equation should be the dry-weight derived from a determination of %moisture of a separate aliquot of the sample using the SOP for Total Solids.

- 13.5 Record all concentrations determined at the instrument and calculate the final results in mg/Kg. Record the final results on the A.A. Benchsheet.
- 13.6 The data packet for the sequence is submitted for review by supervisor or designee. The results are transferred to the appropriate report form located in the ALS network directory R:\ICP\WIP. Once the results are transferred, the report is reviewed.
- 13.7 A daily run log of all samples analyzed is maintained. All data should be printed and stored after operator has checked for evenness of burns. A copy of this document will go with each package of Tier III or higher data run that day.
- 13.8 Refer to the SOP *Laboratory Data Review Process* (ADM-DREV) for general instructions for data review.

#### 14) Method Performance

- 14.1 Available method performance data is given in the reference method. In addition, this procedure was validated through single laboratory studies of accuracy and precision as in the determinative procedure. The method detection limit(s) and method reporting limit(s) are established for the determinative procedure. See *Performing and Documenting Method Detection Limit Studies and Establishing Limits of Detection and Quantitation*.

#### 15) Pollution Prevention and Waste Management

- 15.1 The laboratory will comply with all Federal, State and local regulations governing waste management, particularly the hazardous waste identification rules and land disposal restrictions as specified in the ALS Lab Waste Management Plan.

#### 16) Contingencies for Handling Out-of-Control or Unacceptable Data

- 16.1 Refer to the SOP for *Nonconformance and Corrective Action Procedure* (ADM-NCAR) for procedures for corrective action. Personnel at all levels and positions in the laboratory are to be alert to identifying problems and nonconformities when errors, deficiencies, or out-of-control situations are detected.

#### 17) Training

- 17.1 All analysts performing this analysis are required to read and understand this SOP.

17.2 Training is documented following the *Employee Training and New Employee Orientation* (ADM-TRAIN).

### 18) Method Modifications

18.1 There are no known modifications in this laboratory standard operating procedure from the reference method.

### 19) References

### 20) Changes Since the Last Revision

Summary of Revision Changes			
Revision Number	Effective Date	Document Editor	Description of Changes
21.0	12/4/2020	T. Caron	Updated SOP signatories. Sections 8 & 10: Added the use of an infrared thermometer to verify hot block operating temperature.

### 21) Attachments, Tables, and Appendices

- 21.1 Table 1: Analysis Parameters - M 6100 Mercury Analyzer.
- 21.2 Table 2: Summary of Corrective Actions.

**Table 1**  
**Analysis Parameters M-6100 Mercury Analyzer**

*Analysis Parameters*

**Instrument** M-6100 Mercury Analyzer

**Conditions**

Gas flow (mL/min)	Sample Uptake (s)	Rinse (s)	Read delay (s)	Replicates (#)	Replicate time (s)	Pump speed (%)	Wavelength (nm)
40	30.00	60.00	50.00	4	2.00		253.65

**Instrumental Zero**

Zero before first sample: No  
Zero periodically: Yes  
Before each calibration:

**Baseline Correction**

#1 Start time (s)	#1 End time (s)	#2 Start time (s)	#2 End time (s)
5.00	10.00		

**Standby Mode**

Enabled: Yes  
Standby Options: gas off, lamp off

**Autodilution**

Enabled: No  
Condition:  
Tube # range:  
If no autodilution tubes remaining

**Calibration**

**Settings**

Algorithm	Through blank	Weighted fit	Cal. Type	Recalibration rate	Reslope rate	Reslope standard
Linear	Yes	No	Normal	0	0	N/A

**Limits**

Calibration slope		Reslope		Coeff. of Determination
Lower (%)	Upper (%)	Lower (%)	Upper (%)	
75	125	75	125	0.99500

Error action: Stop analysis

**QC**

GLP Override: Yes

**QC Tests**

Table 2

Summary of Corrective Actions

Method Reference	Control	Specification and Frequency	Acceptance Criteria	Corrective Action
EPA 7471A/B	ICAL	Prior to sample analysis	$R2 \geq 0.995$	Correct problem then repeat ICAL
EPA 7471A/B	ICV	After ICAL	$\pm 10\%$	Correct problem and verify second source standard; rerun second source verification. If fails, correct problem and repeat initial calibration.
EPA 7471A/B	CCV	Prior to sample analysis	$\pm 10\%$	Correct problem then repeat CCV or repeat ICAL
EPA 7471A/B	Method Blank	Include with each analysis batch (up to 20 samples)	<MRL	If target exceeds MRL, reanalyze to determine if instrument was cause. If still noncompliant then:  Re-extract or reanalyze samples containing contaminate, unless samples contain > 20x amount in blank.
EPA 7471A/B	Laboratory Control Sample	Include with each analysis batch (up to 20 samples)	See DQO	If exceeds limits, re-extract and re-analyze
EPA 7471A/B	Matrix Spike	Include with each analysis batch (up to 20 samples)	See DQO	Evaluate data to determine if there is a matrix effect or analytical error
EPA 7471A/B	Sample Duplicates	Include with each analysis batch (up to 20 samples)	$\leq 20\% \text{ RPD}$	Re-homogenize and re-analyze if result is > 5 X the MRL

## Metals Digestion of Aqueous Samples

DOCUMENT ID: MET-DIG REVISION 20.0

Prepared By:   
Inorganics Manager, Jeff Coronado

Date: 12/1/20

Prepared By:   
Quality Assurance Manager, Kurt Clarkson

Date: 12/1/2020

Approved By:   
Laboratory Director, Charles (Pat) Byrne

Date: 12-1-20

## 1) Scope & Applicability

- 1.1 This procedure is used to prepare aqueous samples for determination of metals using ICP and ICP/MS methodologies. This procedure is the ALS default water digestion procedure and is based on methods described in EPA CLP ILM04.0, EPA 200.8, EPA 200.7, and EPA SW-846 3005A.
- 1.2 This procedure is applicable to all "CLP" scope of elements plus boron and molybdenum.
- 1.3 This procedure is used for the determination of dissolved as well as total recoverable metals.
- 1.4 This procedure is applicable to drinking water and non-potable water sample matrices.
- 1.5 In cases where there is a project-specific quality assurance plan (QAPP), the project manager identifies and communicates the QAPP-specific requirements to the laboratory. In general, project specific QAPP's supersede method specified requirements. An example of this are projects falling under DOD ELAP. QC requirements defined in the SOP *Department of Defense Projects - Laboratory Practices and Project Management* (ADM-DOD) may supersede the requirements defined in this SOP.

## 2) Summary of Procedure

- 2.1 A representative aliquot of aqueous sample is digested in nitric, hydrochloric acid, or a mix of acids/reagents. After cooling, the sample is made up to volume prior to analysis.
- 2.2 This digestion procedure is carried out in a Class-10,000 clean room and "Clean" procedures are utilized throughout.

## 3) Definitions

- 3.1 For general definitions applicable to most analyses refer to the SOP for *Sample Batches*, ADM-BATCH.

## 4) Responsibilities

- 4.1 It is the responsibility of the analyst to perform the analysis according to this SOP and to complete all documentation required for data review. Analysis and interpretation of the results are performed by personnel in the laboratory who have demonstrated the ability to generate acceptable results utilizing this SOP. This demonstration is in accordance with the training program of the laboratory. The department supervisor/manager or designee performs final review and sign-off of the data.
- 4.2 It is the responsibility of the department supervisor/manager to document analyst training and method proficiency, as described in the ALS-Kelso SOP: *Employee Training and Orientation*, (ADM-TRAIN).

## 5) Interferences

- 5.1 Refer to the determinative method for a discussion of interferences.

## 6) Safety

- 6.1 Chemicals, reagents and standards must be handled as described in the ALS safety policies, approved methods and in SDSs where available. Refer to the ALS Kelso Chemical Hygiene Plan and the appropriate SDSs prior to beginning this method.
- 6.2 Hydrochloric and/or Nitric Acid are used in this method. These acids are extremely corrosive and care must be taken while handling them. A face shield should be used while pouring acids. And safety glasses should be worn while working with the solutions. Lab coat and gloves should always be worn while working with these solutions.
