SORPTION PARAMETER MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
SWAN ISLAND BASIN PROJECT AREA, CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

1.0 INTRODUCTION

The purpose of this Sorption Parameter Memorandum (SPM) is to present the sorption parameters selected from literature values for CapSIM modeling efforts of chemical isolation layer (CIL) performance. The CIL performance was evaluated for the remedial design (RD) of Swan Island Basin (SIB) Project Area. Values presented in this memo are incorporated into the Pre-Final 90% RD Cap Design Technical Memorandum (CDTM; Volume I, Appendix E).

Sorption models include linear, Freundlich and Langmuir sorption isotherms. The linear sorption model is a widely accepted model for the sorption of organic compounds onto both sediments and natural organic matter (Karickhoff et al., 1979; Reible, 2023) and inorganic constituents to mineral surfaces. Linear model input parameters include adsorption-desorption linear partitioning coefficient (K_D), which depends on the organic carbon-water partition coefficient (Koc), the organic carbon content associated with the solids (foc), and the octanol-water partition coefficient (Kow). Freundlich and Langmuir (non-linear) sorption isotherms are also frequently used to predict particle concentrations from porewater concentrations for cap amendment materials, for compounds and settings that are more appropriately modeled as having non-linear sorption characteristics.

Section 2 discusses literature-based sorption parameters outlined in this SPM. Section 3 discusses Project Area-adjacent sorption parameters. Section 4 details chemical isolation materials used in the design. Section 5 discusses selected sorption parameters for all analytes. Section 6 lists all the references.

2.0 LITERATURE-BASED SORPTION PARAMETERS

A review of sorption parameters available in literature was performed. The values were screened based on conditions under which the sorption parameters were measured such as material type, redox conditions, pH, and environmental setting. The most appropriate available values were selected based on the degree of similarity to in-situ conditions within SIB. The selected sorption parameters for each ROD Errata #2 Table 17 (EPA, 2020) contaminant of concern (COC) and for each capping material are described in detail in Section 5.

3.0 PROJECT AREA-ADJACENT SORPTION PARAMETERS

The SPM evaluates literature K_D values against the Project Area-adjacent K_D values. These Project Area-adjacent specific measurements include 2020 Transition Zone Water investigation from River Mile 9 West (RM9W, Bridgewater Group, 2020), as well as Cathedral Park, and Fund-Lead 3, and Fund-Lead 9 (CDM Smith, 2025) project areas. As discussed in Section 1.2 of the Cap

Corporate Headquarters
11107 Sunset Hills Road, Suite 400
Reston, Virginia 20190
703-478-5186

Design Technical Memorandum, these Project Areas are adjacent to the SIB Project Area, both upstream and downstream and represent the most-similar spatial conditions to the SIB Project Area within the Willamette River. Project Area-adjacent K_D values are used for evaluating partitioning within the SIB sediments when available, as they better represent SIB Project Area conditions than literature values, due to the physical proximity of these reference sites to the SIB Project Area.

These Project Area-adjacent K_D values were:

- calculated from sediment and porewater sampling results (Bridgewater Group, 2020; CDM Smith, 2025);
- available for 34 individual COCs and Total PCBs; and
- compared to literature values previously applied to SIB Project Area in Draft 50% RD.

The Project Area-adjacent measured sorption parameters are lower for 1,2,3,4,7,8-hexachlorodibenzofuran (HxCDF), 1,2,3,7,8- pentachlorodibenzo-p-dioxin (PeCDD), benzo(g,h,i)perylene, and diesel compared to the selected literature values, resulting in equivalent porewater concentrations that are between 170 and 375 percent (average of 292 percent) of the literature equivalent porewater concentrations for the same initial sediment concentrations. The measured sorption parameters for the other 31 COCs are higher than the selected literature values, resulting in equivalent porewater concentrations that are between 0.22 and 93 percent (average of 15 percent) of the literature equivalent porewater concentrations for the same initial sediment concentrations. Section 1.2 of Pre-Final 90% RD discussed the impact of selecting Project Area-adjacent values on cap design.

4.0 MODELED MATERIALS

Section 4 provides a discussion of the sediment and capping materials present in the CIL and evaluated in the CapSIM model. The main CIL components evaluated included sand and activated carbon as an amendment. Multiple additional cap amendment materials were evaluated for arsenic, BEHP, and tributyltin for the 100-year design life based on cap breakthrough of the GAC-amended sand alternatives modeled in the 50% RD CDTM. These additional materials are apatite, bauxite, and organoclay.

4.1 ACTIVATED CARBON

Activated carbon is known to strongly adsorb hydrophobic organic contaminants that are commonly associated with sediments and is one of the most widely accepted treatment amendments (ITRC, 2023). Activated carbon can be used in its raw granulated form (GAC) mixed with sand, in a powdered form (PAC), or in the form of a geotextile mat containing GAC (ITRC, 2023). GAC and GAC geotextile were evaluated in this design due to challenges with uniform placement of PAC and potentially better performance of GAC as compared to PAC for the 100-year cap design life. A key attribute for activated carbon is its high specific surface area resulting from its porous structure. Polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), dioxins/furans, and pesticides, all of which are present in the sediment within SIB Project Area, are strongly adsorbed by activated carbon, often in a granular form, making them less bioavailable (EPA, 2013). Adsorption of hydrophobic organic contaminants to activated carbon in

sediments is often 10 to 100 times greater than absorption to organic carbon (OC) (EPA, 2013). Pre-hydrated activated carbon mixed with sand, as specified in the CDTM, has been applied on full and pilot scales at multiple sites over the last decade (ITRC, 2023).

The physical parameters for GAC as modeled in the Final 90% RD CDTM are based on the commercially available product FILTRASORB 400 manufactured by Calgon Carbon Corporation. FILTRASORB 400 is produced from a pulverized and reagglomerated blend of bituminous coals and has been used in treatment and purification applications for over 40 years (Calgon Carbon Corporation, 2019).

4.2 APATITE

Apatites are a class of naturally occurring minerals that consist of a matrix of phosphate minerals, including calcium phosphate, and other common ions like fluoride, chloride, and hydroxide that sequester metals through direct ion exchange with the calcium atom or by dissolution of hydroxyapatite followed by precipitation of the metal phosphate mineral (ITRC, 2023). Common sources for apatite are processed animal bones and mined fossilized bones, such as from fish. The partition coefficient is sensitive to the equilibrium solution pH and temperature, and the uptake of the contaminant may be diminished by the presence of interfering ions that can affect the solid phase by competitive sorption or by altering of the surface properties (Bostick et al., 2003). Pilot-scale apatite caps have shown reductions in lead, cadmium, and zinc porewater concentrations compared to sand caps (ITRC, 2023).

4.3 BAUXITE

Bauxite is capable of sequestering many heavy metals, including mercury, arsenic, chromium, cadmium, lead, zinc, and nickel (EPA, 2013). Bauxite is a clay-like mineral and a primary ore of aluminum composed of a mixture of aluminum oxides and aluminum hydroxides. The surface properties of bauxite allow it to sequester both cationic and oxy-anionic forms of heavy metals through a combination of sorption, ion-exchange, and precipitation (EPA, 2013). Bench-scale studies have been conducted to evaluate the effectiveness of bauxite, bauxite residue, and red mud (Alcoa), however, there have been no pilot- or full-scale applications (EPA, 2013; ITRC, 2023).

Red mud and bauxite residue have been a growing focus of research efforts, due in part to its quantity generated annually as a solid waste from the alumina, the precursor to aluminum, industry. Bauxite products are attractive adsorbents for arsenic in particular due to the naturally high aluminum oxide (Al_2O_3), iron oxide (Fe_2O_3), and rutile (TiO_2) contents (Anang et al., 2022). However, due to its alkalinity and chemical and mineralogical properties, red mud is classified as a toxic industrial waste which needs to be treated before discharge (Liu et al., 2011). The treatment, or activation, methods vary depending on the origin of the adsorbent and the pollutant to be addressed and changes the physiochemical properties of the material. These are summarized in Table 4 of Liu et al. (2011).

4.4 ORGANOCLAY

Clay minerals are low-cost and nontoxic sorbents. Organophilic clays, also known generically as organoclay, are created by introducing a cationic surfactant to surface of clays (i.e. bentonite), which creates hydrophobic, sorbing layers for nonpolar organics and metals (ITRC, 2023). Organoclays are particularly effective for NAPLs, such as fuels and heavy oils, and dissolved

PAHs. Raw clays are able to sorb cations owing to their negatively charged surface; however, they display low sorption efficiency for negatively charged contaminants such as arsenic (Tuchowska et al., 2019). Similar to activated carbon, weighting agents can be applied to organoclays to overcome placement challenges, and granular organophilic clay can be applied within a geotextile mat.

According to EPA (2007), common earth materials such as clays used in environmental remediation applications can contain traces of the same contaminants creating the hazardous condition at a cleanup site. For instance, common clays often contain heavy metals in some concentration given the ubiquitous geologic presence of metals and the high affinity clays have for metals through cation exchange. However, it is likely that the hazardous condition at a cleanup site would be significantly greater in terms of concentration compared to naturally occurring metal loads in a clay material applied at a site.

4.5 SAND AND SEDIMENT

Unamended granular cap materials are generally intended to physically separate the underlying contaminated sediment and the overlying benthic community and surface water, reducing the diffusive flux of contaminants to the benthically active zone (BAZ) and surface water and the accumulation of contaminants in the BAZ (ITRC, 2023). Granular materials such as sand also compose a major portion of chemical isolation layers, providing both density, stability and a porous, durable material to be combined with reactive amendments.

Sorption for metals to sediment and granular materials, such as capping sand, uses the linear partition coefficient, KD. The relationship between soil organic carbon content and sorption observed for organic chemicals (KOC) does not apply to inorganic constituents. The distribution coefficient KD for metals and other inorganic compounds is affected by numerous geochemical parameters and processes, including pH; sorption to clays, organic matter, iron oxides, and other soil constituents; oxidation/reduction conditions; major ion chemistry; other processes such as precipitation or encapsulation; and the chemical form of the metal (EPA, 2023; European Chemicals Agency, 2008).

4.6 UNIT CONVERSIONS

Sorption isotherms in CapSIM utilize the following units:

- Linear, K_{OC}: log(L/kg)
- Linear, K_D: L/kg
- Freundlich, K_F: $\mu g/kg \Big/ (\mu g/L)^N$
- Freundlich, N (1/n): unitless
- Langmuir, q_{max}: µg/kg
- Langmuir, b: L/µg

Literature sorption parameters are presented in numerous forms depending on experimental measurements[1].

5.0 SELECTED SORPTION PARAMETERS

Section 5 provides a discussion of the selected sorption parameters for the applicable cap materials, including all modeled chemical isolation, erosion protection, and sediment layers.

5.1 APPLICABILITY OF REFERENCED LITATURE

Resources that are were referenced for the sorption parameters for multiple modeled contaminants are described here.

Addeck et al. (2014): The value presented in the Annex of Addeck et al. (2014) was sourced from the Handbook of Physical-Chemical Properties and Environmental Fate for Organic Chemicals (Mackay et al., 2006) and used as a point of comparison for a Project Area-specific K_D determination. The handbook contains physical-chemical property data from peer-reviewed journals and other valuable sources on over 1,200 chemicals of environmental concern.

AECOM (2017): The values presented in Table C-6-2 of AECOM (2017) were used in the transient modeling to support a final cap design for the River Mile (RM) 13.1 Study Area. This site is approximately five miles upstream of the mouth of SIB on the Willamette River. The values were sourced from the Risk-Based Concentrations for Decision Making tables published by the Department of Environmental Quality (DEQ). The modeled cap design was approved, and cleanup was completed in 2017.

Alaska Department of Environmental Conservation, Division of Spill Prevention and Response Contaminated Sites Program (2018): The values presented in Table 7 of Division of Spill Prevention and Response Contaminated Sites Program (2018) are used by the Alaska Department of Environmental Conservation in the selection or development of cleanup levels for contaminated soil and groundwater. The K_{OC} values presented in Table 7 of Division of Spill Prevention and Response Contaminated Sites Program (2018) were selected using the following hierarchy: EPA's Estimation Programs Interface (EPI) Suite software, EPA Soil Screening Level (SSL), Yaws' Handbook of Thermodynamic and Physical Properties of Chemical Compounds, EPI Suite experimental values, and Yaws' Handbook of Thermodynamic and Physical Properties of Chemical Compounds.

Allison & Allison (2005): The values presented in Table 4 of Allison & Allison (2005) are from a literature review of metal partition coefficients for sediment from porewater, and the mean value was used in the Lower Duwamish Waterway Upper Reach 30% RD Basis of Design Report as the partition coefficient for arsenic to sand. The study was contracted by the U.S. Environmental Protection Agency to develop metal partition coefficients for the surface water pathway to be used in the Multimedia, Multi-pathway, Multi-receptor Exposure and Risk Assessment (3MRA) technology. Reviewed studies characterized whole natural media; values were rejected from

[1] Conversions employed in this sorption parameter literature review include the following:

$$\frac{\frac{mmol}{kg}}{\left(\frac{mmol}{L}\right)^{1/n}} \times \frac{\frac{g}{mol}\times 1000}{\left(\frac{g}{mol}\times 1000\right)^{1/n}} = \frac{\frac{ug}{kg}}{\left(\frac{ug}{L}\right)^{1/n}}; \quad \frac{\frac{mmol}{g}}{\left(\frac{mmol}{L}\right)^{1/n}} \times \frac{\frac{g}{mol}\times 1000\times 1000}{\left(\frac{g}{mol}\times 1000\right)^{1/n}} = \frac{\frac{ug}{kg}}{\left(\frac{ug}{L}\right)^{1/n}}; \; and \; \frac{\frac{mg}{g}}{\left(\frac{mg}{L}\right)^{1/n}} \times \frac{1000\times 1000}{(1000)^{1/n}} = \frac{\frac{ug}{kg}}{\left(\frac{ug}{L}\right)^{1/n}}$$

studies that used pure mineral phases or treated soils. The pH values in the studies reviewed by Allison & Allison (2005) were in the natural range (4 to 10). Where multiple partition coefficients are presented for a system due to experimental variation of pH or other parameters, the partition coefficient corresponding to the conditions most closely approximating natural conditions and lowest metal concentration was selected.

Bureau of Habitat (2014): The Bureau of Habitat is a part of the New York State Department of Environmental Conservation. The values presented in Table 2-2 of Pre-Final CDTM (Volume I, Appendix E) are intended to be used to derive Project Area-specific numeric sediment concentrations of individual contaminants that classify the sediment based on the potential for adverse impacts to aquatic life. Table 7, referenced for naphthalene, cites the EPA Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: PAH Mixtures.

California Department of Toxic Substances Control (2009): The guidance document was developed by the Department of Toxic Substances Control (DTSC) Human and Ecological Risk Division (HERD) to address the characterization and risk evaluation of total petroleum hydrocarbons (TPH). The values present in Table 1 are separated by carbon chain length for both aliphatic and aromatic hydrocarbons and the K_{OC} value for C9- C18 aliphatic hydrocarbons was selected as representative of diesel-range hydrocarbons. California Department of Toxic Substances Control (2009) utilized work performed by the Total Petroleum Hydrocarbon Criteria Working Group in 1997 in *Volume 3. Selection of Representative TPH Fractions Based on Fate and Transport Considerations*.

Center for Environmental & Human Toxicology, University of Florida (2005): The value presented in Table 4 was sourced from the EPA Superfund Chemical Data Matrix (SCDM) (EPA/540/R96/028). The SCDM is a database that can be accessed and downloaded via the Internet. The SCDM database is composed of information selected from specified literature sources or other databases, and calculated values. The SCDM then ranks those values that reasonably apply to a hazardous substance and reports a single value for each of the physical/chemical parameters. If the K_{OC} value was not presented in the SCDM, the value was selected using the following hierarchy: calculated from the K_D published in the SCDM using the equation $K_{OC} = K_D / 0.002$, the Estimation Program Interface Suite for Windows (EPIWIN), the Hazardous Substances Data Bank (HSDB), the Agency for Toxic Substances and Disease Registry's Toxicological Profiles (ATSDR), and finally reference texts.

CLARC (2025): The CLARC (2025) data table presents K_{OC}, K_D, and other physical parameters and toxicity of chemicals alongside Washington State and Federal cleanup levels.

Cornelissen et al. (2008): Table 3 of this study reports linear sorption parameters and derived Freundlich sorption parameters using three n parameters in different units. Cornelissen et al. (2008) studied the sorption of PCDD/Fs to total organic carbon, black carbon, and dissolved organic carbon in five soils affected by chlorophenol wood impregnation. All 2,3,7,8-chlorinated PCDD/F congeners were included in the study. Soil samples were collected at a former sawmill site at Marieberg, Sweden where around 260 kg WHO-TEQ PCDD/F are present. The black carbon (BC) was environmental, mainly consisting of soot, and sourced from the collected samples. The BC content was measured in triplicate for each sample and was present at between 0.04 to 0.4 percent. The referenced parameters for CapSIM modeling is under the header $Log\ K_{F,BC}\ n_{F,BC} = 0.61$.

Dobbs & Cohen (1980): This research program was initiated with the overall objective of determining the capability of activated carbon to sorb priority pollutants and other hazardous organic compounds from aqueous solution. Another objective of the study was to standardize the experimental procedure as well as the method of reporting results so that information on adsorption can be compared on a common basis. The approach chosen to describe adsorption was batch equilibrium carbon adsorption isotherms with the results plotted according to the Freundlich adsorption equation. Among the conclusions of the study are that pesticides, PAHs, phthalates, phenolics, and substituted benzenes are readily adsorbed by activated carbon and certain low molecular weight compounds with high polarity are not amenable to activated carbon treatment. Compounds in this category include low molecular weight amines, nitrosamines, glycols, and certain ethers.

EPA (2023): Table 38 of the Superfund Soil Screening Guidance (EPA, 2023) reports summary statistics for K_{OC} values found in a literature review. When K_D was reported instead of K_{OC}, the K_D value was converted using the fractional soil organic carbon content or, if the partition content was normalized to soil organic matter, it was converted using a conversion factor of 1.724 citing Dragun (1988). The geometric mean of the K_{OC} was used because it is a more suitable estimate of the central tendency of a distribution of environmental values with wide variability. For DDD and DDE, Table 39 of the Superfund Soil Screening Guidance (EPA, 2023) was referenced instead of Table 38 due to the sample size of 1 used for K_{OC} determination in Table 38. In Table 39, the K_{OC} value is calculated from the K_{OW} value in the Superfund Chemical Data Matrix using the relationship published by Di Toro (1985).

EPA (n.d.): The Technical Factsheet on Lindane is an archived part of the EPA National Primary Drinking Water Regulations publication. A mean K_{OC} of 1080.9 was obtained from K_{OC} determinations on three soils. The average organic carbon content of the soils used was 13 percent, higher than the f_{OC} measured within SIB sediments (2.36 percent).

Erto et al. (2015): Table 2 of Erto et al. (2015) reports sorption equation parameters for four isotherm regressions. Erto et al. (2015) aimed to study the single and binary adsorption of zinc and cadmium from model aqueous solutions at a constant pH (6.8±0.3) and temperature (20°C). The sorbent used was Aquacarb 207EA™, a commercially available non-impregnated granular activated carbon (GAC), produced by Sutcliffe Carbon starting from a bituminous coal. This study was performed in response to a finding reported in multiple studies that zinc and cadmium compete with one another in binary mixtures, leading to a reduction of their adsorption capacity. Erto et al. (2015) found that while cadmium adsorption is affected by the presence of zinc in solution, zinc adsorption is not affected by the presence of cadmium.

Gomez-Eyles et al. (2013): Table S2 within the supporting information of Gomez-Eyles et al. (2013) reporting the Freundlich isotherm parameters for commercially available carbons. This study aimed to address whether biochars could provide viable alternatives to activated carbons for the in situ remediation of sediments based on partitioning behavior and which types of activated carbons and biochars are most suitable for the in situ treatment of mercury and methylmercury. Gomez-Eyles et al. (2013) evaluated the sorption potential of PCBs, PAHs, DDXs mercury, and methylmercury for 17 commercially available and laboratory synthesized activated carbons and unactivated biochars. The referenced material for CapSIM modeling is the bituminous coal based activated carbon (CAC-Coal) sourced from Calgon Corporation.

Götz et al. (1994): Table 2a presents the calculated K_{OC} values for two sampling points in the river Elbe. The calculated value at the Blankenese sampling station was connected as it is downstream of Hamburg, similar to the positioning of SIB in relation to Portland.

Hawker & Connell (1988): The accuracy of the measurement method used by Hawker & Connell was first confirmed by comparing their results to other accepted literature. After validating a high correlation between the total surface area of the molecule and the K_{OW}, they were able to estimate K_{OW} values for all 209 PCB congeners. This paper has been cited by nearly 700 other publications, most recently in 2023.

Kupryianchyk et al. (2011): Table 1 presents the calculated Freundlich sorption parameters. The study aimed to understand to what extent hydrophobic organic contaminants binding to activated carbon could be generalized for different activated carbon types applied to natural sediment. The analyzed dataset was compiled from four published studies. Equations were derived to represent the equilibrium distributions of contaminants in the sediment before and after the addition of activated carbon. The optimized n value was determined from the smallest variation in calculated Freundlich equations, which was then used in the derived equation to determine the $LogK_F$ value. Kupryianchyk et al. (2011) notes that the derived equation shows the effect of activated carbon dose decreases if more organic matter and black carbon are present in the sediment.

Lin (2014): This is the 3rd edition of the textbook Water and Wastewater Calculations Manual. The isotherms are for the compounds in distilled water, with different activated carbons. Summary sorption isotherms from Lin (2014) are presented in Pre-Final 90% RD (Volume I, Appendix E). The values were sourced from a prior literature review (Snoeyink, 1990).

MFA (2009): The Zidell Waterfront Property on the west side of the Willamette River in Portland, Oregon, upstream of the PHSS. MFA measured Project Area-specific partitioning coefficients during a 2008 sampling event by collecting and analyzing bulk sediment and pore water (K_D). For hydrophobic organic compounds, the partitioning coefficients were normalized to the organic matter found in the sample (K_{OC}). Table 3-2 of MFA (2009) reports the Project Area-specific partitioning coefficient for tributyltin measured at the Zidell Waterfront Property as the standard value, which was used as the K_{OC} in cap design modeling for the Zidell project area. The standard was also determined to fall within the literature review completed by the Zidell Waterfront Property design team. Table 3-4 of MFA (2009) reports a summary of Project Area-specific partitioning coefficients that were measured at the Zidell Waterfront Property and were used in their chemical isolation layer model, a precursor to CapSIM.

New Mexico Environment Department (2021): The values presented in Table B-2 of New Mexico Environment Department (2021) were used by the New Mexico Environment Department (NMED) Hazardous Waste Bureau (HWB) and the Ground Water Quality Bureau Voluntary Remediation Program to derive the State of New Mexico Soil Screening Levels. The K_{OC} value presented in Table B-2 of New Mexico Environment Department (2021) was selected from EPA's Estimation Programs Interface (EPI) Suite software. This K_{OC} value is in agreement with Alaska Department of Environmental Conservation, Division of Spill Prevention and Response Contaminated Sites Program (2018).

NJDEP (2014): Table 1 in the NJDEP (2014) guidance document presents the chemical properties approved by NJDEP for use in the SESOIL and AT123D models when evaluating contaminated

sites managed by the New Jersey Department of Environmental Protection. These values are taken from the 2008 New Jersey DEP Remediation Standards Chemical Properties and Soil Saturation Limits.

PHSS Remedial Investigation (RI)/Feasibility Study (FS) (2016): The values presented in Table D-7 in Appendix D, Supporting Information for Alternative Development, of the PHSS RI/FS were calculated using the regression equation: $\log(K_{OC}) = 0.903 \times \log(K_{OW}) + 0.904$. This report was prepared for, and accepted by, the EPA specifically for PHSS.

Roy F. Weston, Inc. (1996): The value reported in Section 3.6 was sourced from measurements completed by Meador et al. (1996). The research completed by Meador et al. (1996) varied the organic carbon content and studied the bioavailability of tributyltin by measuring the bulk sediment, interstitial water, and tissue concentrations. The sediment used was a mixture from three sites within the northern Puget Sound. The average K_{OC} value was measured as 25,100 L/kg, and referenced similarity to Unger et al. (1988). The range in calculated K_{OC} values was 23,400 to 104,700 L/kg for organic carbon ranging from 0.1 to 1.0 percent. Roy F. Weston, Inc. (1996) notes that environmental factors such as salinity, pH, organic carbon, and sorption capacity of the sediment strongly influence the form and fate of tributyltin in aquatic environments and thus its bioavailability, as does the phase and form in which tributyltin is introduced into the environment. Roy F. Weston, Inc. (1996) additionally notes that there are uncertainties associated with the use of a single K_{OC} value to estimate interstitial water tributyltin concentrations as statistical analyses of existing data suggest there is not a strong correlation between sediment tributyltin concentrations and total organic carbon.

Schwarzenbach et al. (2017): This is the 3rd edition of the textbook Environmental Organic Chemistry. EPA's Health & Environmental Research Online (HERO) entry for the second edition of the textbook shows 8,400 citations.

The Louis Berger Group et al. (2014): Table 3-7 of The Louis Berger Group et al. (2014) lists the constants used for each chemical in the contaminant fate and transport modeling completed for the Lower Passaic River as part of the analysis of potential remedial alternatives. The remedial alternatives were evaluated by EPA as part of a focused feasibility study of the lower eight miles of the Lower Passaic River. The chemical properties used and presented in Table 3-7 are largely the same as those used in the peer reviewed model developed for NY/NJ Harbor Contaminant Assessment and Reduction Project (CARP).

Unger et al. (1988): Unger et al. (1988) measured the sorption of tributyltin in aqueous solution to natural sediments under various salinity conditions. Sorption coefficients were calculated from environmental water and sediment concentrations at various locations in the Chesapeake Bay region and compared to equilibrium sorption coefficients determined in the laboratory. The organic carbon content for the collected samples ranged from 0.34 to 19.8 percent and the clay content ranged from 17.9 to 58.4 percent. In the SIB project area, the organic carbon content is 2.36 percent and the average clay content is approximately 27 percent. The K_{OC} value utilized is the average of the four calculated K_{OC} values presented in Table 2.

Walters and Luthy (1984): The isotherm equations are presented in Table III of Walters and Luthy (1984). The study measured the sorption of 11 PAHs from water onto FILTRASORB 400 at 25°C. To reduce equilibration time, the activated carbon was mechanically ground and classified to 200

mesh (0.074 mm). The water used for preparation of the aqueous solutions typically had a pH in the range 6.8-7.2, similar to slightly higher than the expected pH at the site (approximately 6.4). This research was prompted by the World Health Organization (WHO) recommending a limit for PAHs in drinking water and the inclusion of PAHs in the EPA list of priority pollutants.

5.2 1,2,3,4,7,8-HXCDF

5.2.1 Activated Carbon

The utilized sorption parameter for 1,2,3,4,7,8-HxCDF to GAC was sourced from Cornelissen et al. (2008). The Freundlich sorption isotherms are presented in Table 3.

5.2.1.1 Modeled Sorption Isotherm

Cornelissen et al. (2008) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 7.80$; $K_F = 6.31 \times 10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.61

5.2.2 Sand

Sorption for 1,2,3,4,7,8-HxCDF to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. A literature review was conducted, and the source identified to be applicable to the sorption of 1,2,3,4,7,8-HxCDF to Sand was Addeck et al. (2014).

5.2.3 Sediment

5.2.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for 1,2,3,4,7,8-HxCDF to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area Fund-Lead 3 and presented in Table E-2 of the SPDI Evaluation. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.2.3.2 Modeled Sorption Isotherm

The Fund-Lead linear (K_D) isotherm, used in CapSIM modeling:

- $K_D = 5.30$ log(L/kg) = 199,526.23 L/kg
- n = 1

5.3 1,2,3,7,8-PECDD

5.3.1 Activated Carbon

The utilized sorption parameter for 1,2,3,7,8-PeCDD to GAC was sourced from Cornelissen et al. (2008). The Freundlich sorption isotherms are presented in Table 3.

5.3.1.1 Modeled Sorption Isotherm

Cornelissen et al. (2008) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 7.10$; $K_F = 1.26 \times 10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.61

5.3.2 Sand

Sorption for 1,2,3,7,8-PeCDD to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The sorption parameter for 1,2,3,7,8-PeCDD to Sand was retrieved from Götz et al. (1994).

5.3.3 Sediment

5.3.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for 1,2,3,7,8-PeCDD to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project areas Cathedral Park, Fund-Lead 3, and Fund-Lead 9. The calculated K_D values from Cathedral Park, Fund-Lead 3, and Fund-Lead 9 presented in Table E-2 of the SPDI Evaluation were averaged. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.3.3.2 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm:

- $K_D = 4.69$ log(L/kg) = 48,977.88 L/kg L/kg
- $R^2 = 0.80$
- n = 4

The Fund-Lead 3 linear (K_D) isotherm:

- $K_D = 4.92$ log(L/kg) = 83,176.38 L/kg
- n = 1

The Fund-Lead 9 linear (K_D) isotherm:

- $K_D = 4.70$ log(L/kg) = 50,118.72 L/kg
- n = 1

The average linear (K_D) isotherm used in CapSIM modeling:

- K_D = 60,757.66 L/kg

5.4 1-METHYLNAPHTHALENE

5.4.1 Activated Carbon

The utilized sorption parameter for 1-methylnaphthalene to GAC was sourced from GeoEngineers (2022). GeoEngineers (2022) is the Basis of Design Report for the Crawford Street South Site in Portland, Oregon. This site is upland approximately two miles downstream of the mouth of SIB on the Willamette River. The sorption isotherms are presented in Table 15 of this report and credit Walters and Luty (1984), Cohen and Dobbs (1980), Hu et al. (2007), and Kupryianchyk et al. (2012) for PAHs.

5.4.1.1 Modeled Sorption Isotherm

GeoEngineers (2022) reports a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 2.01\times10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.43

5.4.2 Sand and Sediment

Sorption for 1-methylnaphthalene to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. A literature review was conducted, and the source identified to be applicable to the sorption of 1-methylnaphthalene to sand and sediment was Table B-2 of New Mexico Environment Department (2021). This K_{OC} value is in agreement with Alaska Department of Environmental Conservation, Division of Spill Prevention and Response Contaminated Sites Program (2018).

5.5 2,3,4,7,8-PECDF

5.5.1 Activated Carbon

The utilized sorption parameter for 2,3,4,7,8-PeCDF to GAC was sourced from Cornelissen et al. (2008). The Freundlich sorption isotherms are presented in Table 3.

5.5.1.1 Modeled Sorption Isotherm

Cornelissen et al. (2008) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 7.30$; $K_F = 2.00\times10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.61

5.5.2 Sand

Sorption for 2,3,4,7,8-PeCDF to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The sorption parameter for 2,3,4,7,8-PeCDF to Sand was retrieved from PubChem (n.d.). PubChem is an open chemistry database at the National Institutes of Health (NIH) National Library of Medicine that accepts data from academic labs, governmental agencies, chemical supply and pharmaceutical companies, journal publishers, and individual researchers. The estimated K_{OC} was

determined from a published log K_{OW} (Sijm et al., 1989) and a regression-derived equation (Lyman et al., 1990).

5.5.3 Sediment

5.5.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for 2,3,4,7,8-PeCDF to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area Cathedral Park and presented in Table E-2 of the SPDI Evaluation. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.5.3.1 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm, used in CapSIM modeling:

- K_D = 4.02 log(L/kg) = 10,471.29 L/kg
- n = 1

5.6 2,3,7,8-TCDD

5.6.1 Activated Carbon

The utilized sorption parameter for 2,3,7,8-TCDD to GAC was sourced from Cornelissen et al. (2008). The Freundlich sorption isotherms are presented in Table 3.

5.6.1.1 Modeled Sorption Isotherm

Cornelissen et al. (2008) reports a non-linear isotherm, used in the CapSIM modeling:

- Log(K_F) = 6.60 ; $K_F = 3.98 \times 10^6$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.61

5.6.2 Sand and Sediment

Sorption for 1,3,7,8-TCDD to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. The sorption parameter for 2,3,7,8-TCDD to sand and sediment was retrieved from Washington State Department of Ecology's CLARC database (CLARC, 2025). This K_{OC} value is in agreement with New Mexico Environment Department (2021).

5.7 2,3,7,8-TCDF

5.7.1 Activated Carbon

The utilized sorption parameter for 2,3,7,8-TCDF to GAC was sourced from Cornelissen et al. (2008). The Freundlich sorption isotherms are presented in Table 3.

5.7.1.1 Modeled Sorption Isotherm

Cornelissen et al. (2008) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 6.80$; $K_F = 6.31 \times 10^6$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.61

5.7.2 Sand

Sorption for 2,3,7,8-TCDF to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. A literature review was conducted, and the source identified to be applicable to the sorption of 2,3,7,8-TCDF to Sand was Addeck et al. (2014).

5.7.3 Sediment

5.7.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for 2,3,7,8-TCDF to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project areas Cathedral Park and Fund-Lead 3. The calculated K_D values from Cathedral Park and Fund-Lead 3 presented in Table E-2 of the SPDI Evaluation were averaged. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.7.3.2 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm:

- K_D = 5.37 log(L/kg) = 234,422.88 L/kg L/kg
- $R^2 = 0.39$
- n = 6

The Fund-Lead 3 linear (K_D) isotherm:

- K_D = 2.82 log(L/kg) = 660.69 L/kg
- $R^2 = 0.05$
- n = 2

The average linear (K_D) isotherm used in CapSIM modeling:

- K_D = 117,542 L/kg

5.8 2-METHYLNAPHTHALENE

5.8.1 Activated Carbon

The utilized sorption parameter for 2-methylnaphthalene to GAC was sourced from GeoEngineers (2022). GeoEngineers (2022) is the Basis of Design Report for the Crawford Street South Site in Portland, Oregon. This site is upland approximately two miles downstream of the mouth of SIB on the Willamette River. The sorption isotherms are presented in Table 15 of this report and credit Walters and Luty (1984), Cohen and Dobbs (1980), Hu et al. (2007), and Kupryianchyk et al. (2012) for PAHs.

5.8.1.1 Modeled Sorption Isotherm

GeoEngineers (2022) reports a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 2.01 \times 10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.43

5.8.2 Sand and Sediment

Sorption for 2-methylnaphthalene to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. A literature review was conducted, and the source identified to be applicable to the sorption of 2-methylnaphthalene to sand and sediment was Table B-2 of New Mexico Environment Department (2021). This K_{OC} value is in agreement with Alaska Department of Environmental Conservation, Division of Spill Prevention and Response Contaminated Sites Program (2018).

5.9 ACENAPHTHENE

5.9.1 Activated Carbon

The utilized sorption parameter for acenaphthene to GAC was sourced from Walters & Luthy (1984). The sorption isotherms are presented in Table III of this study. The Langmuir isotherm was determined by the researchers to be the most useful of the evaluated equations for representing the data. However, the Langmuir equation was not capable of describing the adsorption over the entire concentration range. The experimental data was reasonably fit by the Freundlich isotherm and was therefore selected. This value was additionally utilized by GeoEngineers (2022) and is lower, and therefore more conservative, than the reported isotherm in Gomez-Eyles et al. (2013).

5.9.1.1 Modeled Sorption Isotherm

Walters & Luthy (1984) reports a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 624$ (mg/g)/((mg/L)^(1/n)) = 2.66×10^7 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.457
- $R^2 = 0.87$

5.9.2 Sand

Sorption for acenaphthene to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Texas Commission on Environmental Quality's published Toxicity Values and Chemical – Physical Properties (TCEQ, 2019).

5.9.3 Sediment

5.9.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for acenaphthene to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project areas Cathedral Park and Fund-Lead 3. The calculated K_D values from Cathedral Park and Fund-Lead 3 presented in Table E-2 of the SPDI Evaluation were averaged. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.9.3.2 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm:

- K_D = 3.44 log(L/kg) = 2,754.23 L/kg L/kg
- R^2 = 0.95
- n = 14

The Fund-Lead 3 linear (K_D) isotherm:

- K_D = 0.85 log(L/kg) = 7.08 L/kg
- R^2 = 0.70
- n = 3

The average linear (K_D) isotherm used in CapSIM modeling:

- K_D = 1,380.65 L/kg

5.10 ACENAPHTHYLENE

5.10.1 Activated Carbon

The utilized sorption parameter for acenaphthylene to GAC was sourced from Walters & Luthy (1984). The sorption isotherms are presented in Table III of this study. The Langmuir isotherm was determined by the researchers to be the most useful of the evaluated equations for representing the data. However, the Langmuir equation was not capable of describing the adsorption over the entire concentration range. The experimental data was reasonably fit by the Freundlich isotherm and was therefore selected. This value was additionally utilized by GeoEngineers (2022).

5.10.1.1 Modeled Sorption Isotherm

Walters & Luthy (1984) reports a non-linear isotherm, used in the CapSIM modeling:

- K_F = 266 (mg/g)/((mg/L)^(1/n)) = 3.30×10^7 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.302
- R^2 = 0.88

5.10.2 Sand and Sediment

Sorption for acenaphthylene to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. A literature review was conducted, and the source identified to be applicable to the sorption of acenaphthylene to sand and sediment was Table 7 of Alaska Department of Environmental Conservation, Division of Spill Prevention and Response Contaminated Sites Program (2018).

5.11 ALDRIN

5.11.1 Activated Carbon

The utilized sorption parameter for aldrin to GAC was sourced from Dobbs & Cohen (1980). This is the same value as is reported in Lin (2014).

5.11.1.1 Modeled Sorption Isotherm

Dobbs & Cohen (1980) reports a non-linear isotherm, used in the CapSIM modeling:

- K_F = 651 (mg/g)/((mg/L)^(1/n)) = 1.13×10^6 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.92
- R^2 = 0.97

5.11.2 Sand and Sediment

Sorption for aldrin to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. The default K_{OC} value in CapSIM was utilized, which was sourced from Texas Commission on Environmental Quality's published Chemical/Physical Properties Table accompanying the Texas Risk Reduction Program (TRRP) Rule (TCEQ, 2023). This K_{OC} value is in agreement with the geometric mean in Table 38 of the Superfund Soil Screening Guidance (EPA, 2023).

5.12 ANTHRACENE

5.12.1 Activated Carbon

The utilized sorption parameter for anthracene to GAC was sourced from Walters & Luthy (1984). The sorption isotherms are presented in Table III of this study. The Langmuir isotherm was determined by the researchers to be the most useful of the evaluated equations for representing the data. However, the Langmuir equation was not capable of describing the adsorption over the entire

concentration range. The experimental data was reasonably fit by the Freundlich isotherm and was therefore selected. This value was additionally utilized by GeoEngineers (2022).

5.12.1.1 Modeled Sorption Isotherm

Walters & Luthy (1984) reports a non-linear isotherm, used in the CapSIM modeling:

- K_F = 330 (mg/g)/((mg/L)^(1/n)) = 4.56×10^6 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.62
- R^2 = 0.81

5.12.2 Sand

Sorption for anthracene to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Texas Commission on Environmental Quality's published Toxicity Values and Chemical – Physical Properties (TCEQ, 2019). This K_{OC} value is in agreement with the geometric mean in Table 38 of the Superfund Soil Screening Guidance (EPA, 2023).

5.12.3 Sediment

5.12.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for anthracene to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area Cathedral Park and presented in Table E-2 of the SPDI Evaluation. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.12.3.1 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm, used in CapSIM modeling:

- K_D = 4.15 log(L/kg) = 14,125.38 L/kg
- n = 1

5.13 ARSENIC

Arsenic can combine with other elements to form both organic and inorganic compounds. In soil and water, arsenic exists primarily in the more toxic inorganic forms, including arsenite [As(III)] and arsenate [As(V)], and As(V) predominates near pH 6-9 and in oxic environments (Kanel et al., 2005; Bostick et al., 2003). As(V) adsorption onto soil components are better understood compared to As(III) and takes place through an inner-sphere complex via ligand-exchange mechanism (Müller et al., 2010). As(III) may form under mildly reducing conditions and in addition to a higher toxicity it is also more mobile due to its neutral character in a wide pH range, resulting in a weaker adsorption to soil constituents such as iron and aluminum hydroxides (Müller

et al., 2010). The speciation of arsenic in sediment samples collected at SIB and other PHSS project areas is not specified in analytical reports.

5.13.1 Activated Carbon

5.13.1.1 Literature Review

In the Draft 50% RD CDTM, the utilized sorption parameter for arsenic to GAC was sourced from Gu et al. (2005) and reduced by an order of magnitude to have a conservative model. The research presented in Gu et al. (2005) focused on iron-impregnated GAC (GAC-Fe) for effective drinking water treatment. The sorption isotherms for un-modified GAC are presented in Table 3 of this study as a control. Notable experimental assumptions and processes include:

- Analyzed total arsenic (As(III) and As(V))
- 13 GAC materials were modified and analyzed in the study, and the untreated GAC was Dacro20 × 40LI, sourced from ANCI
- Solution pH was 4.70, lower than the expected pH at the site (approximately 6.4)
- Temperature was 25.0 ± 1°C, higher than the expected temperature at the site (averaging between 4°C and 22°C)

Values from Gu et al (2005) study were used in the Draft 50% RD. However, sorption of arsenic seemed to have limitations. To overcome this limitation, additional literature review was conducted, evaluating if perhaps a different material (as opposed to GAC produced by Dacro), had better performance. Four additional sources were identified that are applicable to the sorption of arsenic to GAC: Deliyanni & Bandosz (2011), Nieto-Delgado et al. (2019), Velazquez-Jimenez et al. (2018), and Vitela-Rodriguez & Rangel-Mendez (2013). Deliyanni & Bandosz (2011) utilized activated carbon BAX-1500 manufactured by Mead Westvaco. The study analyzed As(V) at a pH of 5.84, closer to expected conditions in the sediment cap. Nieto-Delgado et al. (2019) performed their study using FILTRASORB® F-400 that was reduced to a particle diameter of 850 micrometers and analyzed As(V) sorption. Velazquez-Jimenez et al. (2018) also studied As(V) sorption to FILTRASORB® F-400, maintaining experimental conditions of pH 7 and a temperature of 25°C. Vitela-Rodriguez & Rangel-Mendez (2013) also studied As(V) sorption to FILTRASORB® F-400. Vitela-Rodriguez & Rangel-Mendez (2013) additionally concluded that the As(V) adsorption capacity of activated carbons increases after modification to impregnate the material with additional iron, temperature does not significantly affect As(V) adsorption capacity, and As(V) adsorption capacity decreases 32 percent when the solution pH increases from 6 to 8.

The experimental amount adsorbed (q; µg/kg) was plotted against the equilibrium concentration (C; µg/L) for all five studies (Figure C-1 below) and it was determined that the literature values reported in Gu et al (2005) for sorption of arsenic to GAC, for GAC manufactured by Dacro appear to substantially underestimate GAC performance as compared to studies that evaluated sorption of arsenic to FILTRASORB® GAC material manufactured by CalgonCarbon or Nuchar® BAX-1500 GAC material, manufactured by Ingevity. FILTRASORB® GAC and BAX-1500 seemed to have comparable performance, indicating that using Gu et al. (2005) values might have underestimated GAC performance in the 50% RD. As a result of this evaluation and due to availability of literature values for FILTRASORB® F-400, F-400 was used in modeling efforts in Pre-Final 90% RD CDTM, alongside its material properties (bulk density, particle size, and permeability). Sorption parameters used in Pre-Final 90%RD include data from both

FILTRASORB® F-400 and BAX-1500 performance (as indicated by black squares in Figure C-1 below).

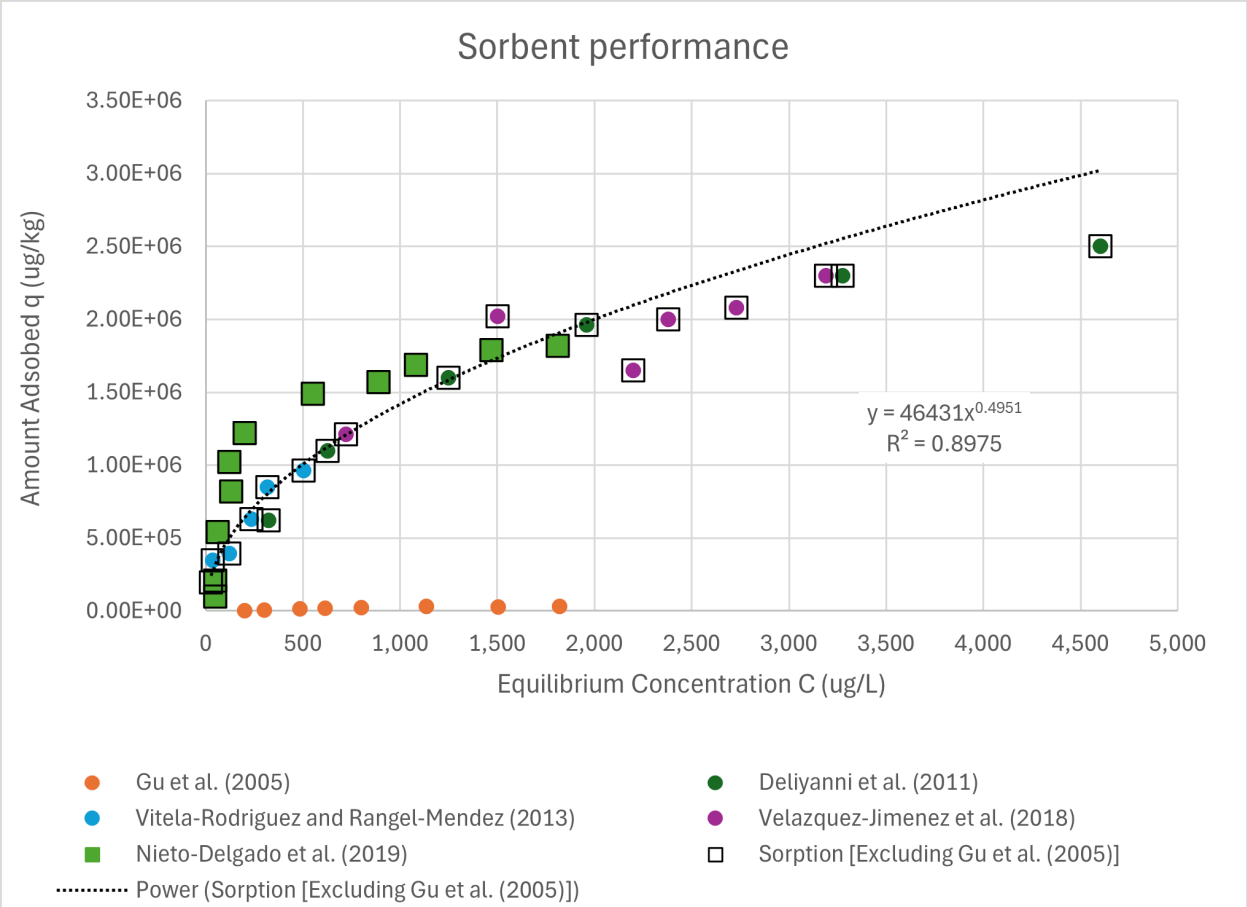

Figure C-1. GAC sorption of Arsenic

5.13.1.2 Modeled Sorption Isotherm

The combined experimental data from Deliyanni & Bandosz (2011), Nieto-Delgado et al. (2019), Velazquez-Jimenez et al. (2018), and Vitela-Rodriguez & Rangel-Mendez (2013) was fit with the Freundlich (nonlinear) equation. The modeled sorption isotherm in the Pre-Final 90% RD CDTM is:

- K_F = 46,430.86 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.4951
- R^2 = 0.8975

5.13.2 Apatite

5.13.2.1 Literature Review

Akartasse et al. (2017) found that hydroxyapatite (HAp) has low adsorption capacity for metal, attributed to the limited number of coordination sites on HAp. However, its highly porous structure

makes it attractive for enhancing its adsorbent efficiency for metals by binding it with a material that has a good chemical affinity for HAp and metals. Consistent with this finding, the majority of available literature that presented experimental results and calculated sorption parameters applicable for arsenic in sediment focused on various HAp composites as the primary sorbent.

The work completed by Bostick et al. (2003) was contracted by the U.S. Department of Energy to understand the performance of remedial technologies for metal-contaminated Federal and civilian sites. The study utilized commercially available biogenic (fish bone) Apatite II^{TM}. Apatite II works by providing phosphate ion to the solution phase to precipitate metal phosphate solids and inducing the precipitation of metals into other phases such as carbonates, oxides, and hydroxides. Nanocrystals in the Apatite II structure additionally provide sites to nucleate the metal precipitates (Bostick et al., 2003). The sorption isotherms for raw apatite are presented in Table 11 of Bostick et al. (2003). Notable experimental assumptions and processes include:

- Analyzed As(V)
- Initial pH was 7.6 and Final pH was 7.15, higher than the expected pH at the site (approximately 6.4)

Bostick et al. (2003) notes that the conditional value for K_D is sensitive to the equilibrium solution pH value and the solution temperature. Additionally, in batch tests for a number of media (natural and synthetic apatites, tricalcium phosphate, bone char, zeolite, magnetite, etc.) only a limited affinity for As(V) was observed, however, improvement was observed in column tests containing multi-metals. Therefore, it is possible that removal of As(V) is enhanced by synergistic co-precipitation with other cationic metals, which are present in the sediment at SIB, in the formation of a mixed phosphate-arsenate mineral phase or phases.

5.13.2.2 Modeled Sorption Isotherm

The slope of the short-term (52-hour) sorption data, presented as a linearized Freundlich isotherm, is near unity, suggesting that the data can be adequately represented as a simple linear sorption isotherm:

- K_D = S(calc)/Ce = 18.4 mL/g

5.13.3 Bauxite

5.13.3.1 Literature Review

A literature review was conducted, and two sources were identified that are applicable to the sorption of arsenic to bauxite: Anang et al., (2022) and Genç-Fuhrman et al., (2004). Anang et al., (2022) utilized five combinations of unmodified and thermally modified yellow and red lateritic bauxite (TYB + TRB) that was reduced to a particle diameter of 850 µm and analyzed total arsenic. Genç-Fuhrman et al. (2004) evaluated As(V) sorption to Bauxsol and activated Bauxsol and As(III) sorption to activated Bauxsol.

Anang et al. (2022) studied multiple bauxite combinations to quantify the affect of bauxite type and modification processes. Thermal modification has been reported to increase the surface area of an earth material, change its chemical composition, and improve its adsorption property. Similarly, the blended yellow and red lateritic bauxite have markedly significant levels of chemical

composition. The observed removal efficiency was observed at pH 4 and 400°C, below the expected sediment pH and far exceeding natural temperatures. The sorption isotherms for the best performing combination, TYB + TRB, are presented in Table 2 of Anang et al. (2022). Notable experimental assumptions and processes include:

- pH was 6.0 ± 0.1, similar to the expected pH at the site (approximately 6.4)
- Temperature was 25 ± 1 °C, higher than the expected temperature at the site (averaging between 4°C and 22°C)

Genç-Fuhrman et al. (2004) was also studying the impact of activating bauxite prior to use as an adsorbent for arsenic and the influence of contact time, particle size, pH, and initial arsenic concentration on the efficacy of the treatment. The calculated sorption isotherms for the varied initial concentrations, temperatures, pH, and sorbent are presented in Table 3 of Genç-Fuhrman et al. (2004) and the conditions most similar to SIB were selected. Notable experimental assumptions and processes for the selected sorption parameters include:

- As(V) to Bauxsol
- Initial arsenic concentration was between 0.80-32.00 µmol/L (59.94-2,397 µg/L)
- Performed at room temperature (23°C ± 1 °C), higher than the expected temperature at the site (averaging between 4°C and 22°C)
- pH was 6.3 ± 0.1, similar to the expected pH at the site (approximately 6.4)

5.13.3.2 Modeled Sorption Isotherm

The experimental adsorption from Anang et al., (2022) most closely followed the Freundlich (nonlinear) equation, however, the Freundlich isotherm was not reported with the necessary shape parameter (N). The Langmuir (nonlinear) fit is consistent with the better fit from Genç-Fuhrman et al. (2004) and was retained:

- q_{max} = 57.77 mg/g = 5.777×10^7 µg/kg
- b = 27.31 L/mg = 0.02731 L/ug
- R^2 = 0.6337

The experimental adsorption from Genç-Fuhrman et al. (2004) most closely followed the Langmuir (nonlinear) equation and was presented in units of mmol. The values below were converted using the molecular weight of arsenic (74.9216 g/mol):

- q_{max} = 14.43 mmol/g = 1.081×10^9 µg/kg
- b = 0.27 L/umol = 0.003604 L/ug
- R^2 = 0.95

The sorption parameters were modeled individually as they represent different bauxite sources and treatments.

5.13.4 Organoclay

5.13.4.1 Literature Review

A literature review was conducted, and two sources were identified that are applicable to the sorption of arsenic to organoclay: Sarkar et al. (2012) and Tuchowska et al. (2019). Tuchowska et al. (2019) notes that raw clays are low-cost, nontoxic sorbents that are able to sorb cations owing to their negatively charged surface; however, they display low sorption efficiency for negatively charged contaminants such as arsenic. Both studies tested surface modifications, and the experimental results using hexadecyl trimethylammonium bromide (HDTMA) were chosen based on the frequency of the treatment in organoclay literature. Sarkar et al. (2012) utilized bentonite clay prepared with HDTMA and analyzed As(V) sorption. Tuchowska et al. (2019) utilized organo-vermiculite with a size fraction of 0.25–1 mm modified with HDTMA and analyzed both As(III) and As(V) sorption. The sorption parameters for As(V) were selected.

Sarkar et al. (2012) studied the modification of silicate clay minerals by the introduction of organic molecules into the mineral structure. The calculated sorption isotherms for the HDTMA and Arquad modified organoclays from are presented in Table 1 of Sarkar et al. (2012). Notable experimental assumptions and processes include:

- Temperature was 23°C, higher than the expected temperature at the site (averaging between 4°C and 22°C)
- Initial pH of the contaminated soil was 6.7, similar to the expected pH at the site (approximately 6.4)

Tuchowska et al., (2019) expanded on the available organoclay literature by studying modified organo-vermiculites. Vermiculite is a 2:1 phyllosilicate mineral that has a large internal surface, high cation exchange capacity (CEC), and high negative charge on the silicate layers. Therefore, addition of a surfactant is necessary for the sorption of anions. The sorption isotherms from Tuchowska et al. (2019) onto raw and modified vermiculite are presented in Table S1. Notable experimental assumptions and processes include:

- Temperature was 20 ± 1 °C, within the expected temperature range at the site (averaging between 4°C and 22°C)
- Initial pH value equal to 6, similar to the expected pH at the site (approximately 6.4)

5.13.4.2 Modeled Sorption Isotherm

The experimental adsorption is reported in Table 1 of Sarkar et al. (2012) for both HDTMA and Arquad modified organoclay and closely followed the Freundlich (nonlinear) equation. The applicable units were defined in Section 4.2.1.

- K_F = 2.69 (mg/g)/((mg/L)^(1/n)) = 33,964 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.6329
- R^2 = 0.982

The experimental adsorption is reported in Table S1 of Tuchowska et al. (2019) for 1.0 HDTMA-As(V) in both the Freundlich and Langmuir (nonlinear) equations and was presented in units of

mmol. The conversions below were converted following the convention shown in Section 4.6 using the molecular weight of arsenic (74.9216 g/mol):

- K_F = 12.7 (mmol/kg)/((mmol/L) ^(1/n)) = 1,210.3 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.594
- R^2 = 0.9143

The experimental amount adsorbed (q; µg/kg) and equilibrium concentration (C; µg/L) were interpreted from available plots in Sarkar et al. (2012) and Tuchowska et al. (2019). The data from the two studies were plotted together (Figure C-2 below) and fit with the Freundlich (nonlinear) equation to reflect the best fit of the original studies:

- Kf = 344,862 (µg/kg)/((µg/L)^(1/n))
- N = 1/n = 0.1619
- R^2 = 0.3886

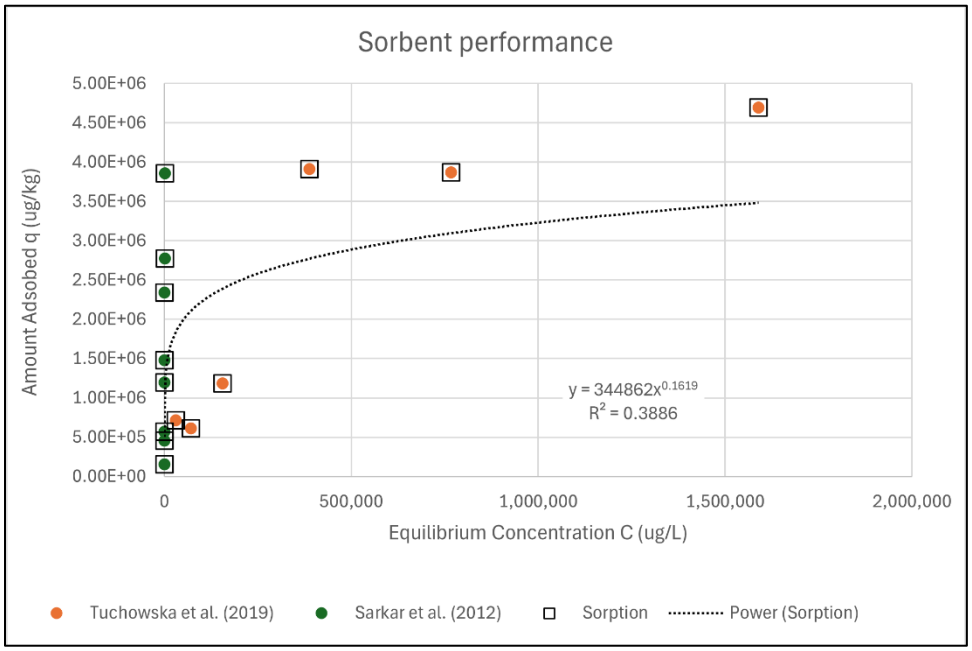

Figure C-2. Organoclay sorption of Arsenic – Freundlich

The combined experimental data was additionally fit with the Langmuir (nonlinear) equation (Figure C-3 below), which better fit the larger dataset. Q_{max} is defined as the inverse of the slope, and b is the inverse of the intercept multiplied by q_{max}.

- $q_{max} = 4.74 \times 10^6$ µg/kg
- $b = 1.000 \times 10^{-5}$ L/ug
- R^2 = 0.8761

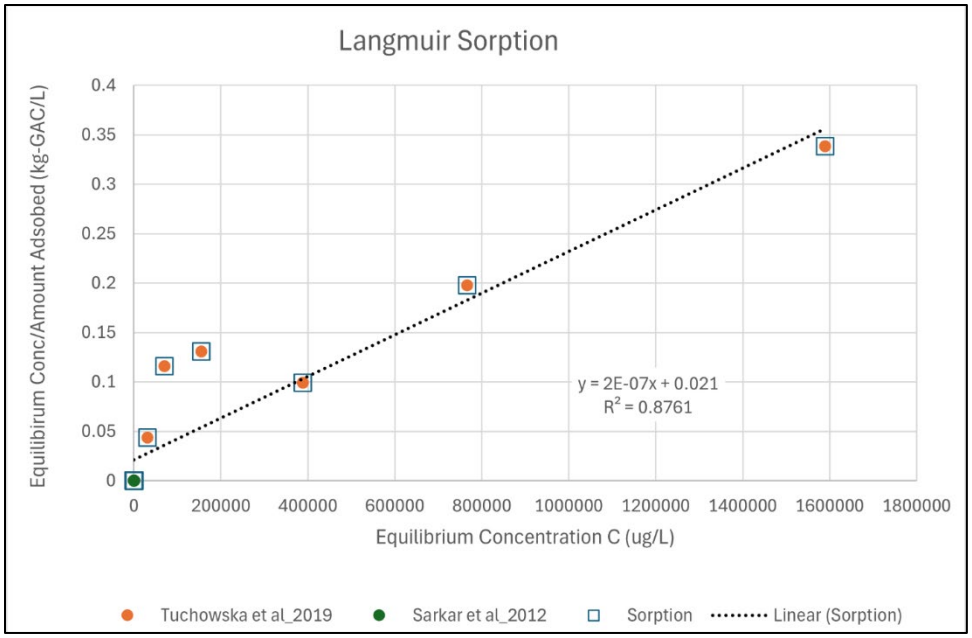

Figure C-3 Organoclay sorption of Arsenic – Langmuir

5.13.5 Sand

5.13.5.1 Literature Review

Sorption for arsenic to granular materials, such as capping Sand, uses the linear partition coefficient, K_D. A literature review was conducted, and three sources were identified that are applicable to the sorption of arsenic to Sand: Allison & Allison (2005), CLARC (2025), and NJDEP (2014). The published metal partitioning data does not allow differentiation of As(III) and As(V). It is probable that the data presented include results for both oxidation states.

5.13.5.2 Modeled Sorption Isotherm

The Allison & Allison (2005) literature review reports a linear (K_D) isotherm:

- K_D = 2.4 log(L/kg) = 251.19 L/kg

The CLARC (2025) data table reports a linear (K_D) isotherm:

- K_D = 29 L/kg

The NJDEP (2014) guidance document reports a linear (K_D) isotherm:

- K_D = 26 L/kg

An average of the three sources was used in CapSIM modeling:

- K_D = 102.06 L/kg

5.13.6 Sediment

5.13.6.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, the utilized sorption parameter (K_D) for arsenic to sediment, 237.36 L/kg, was based on the average of the median linear sorption parameters presented in Tables 1 and 4 of Allison & Allison (2005). Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project areas River Mile 9 West (RM9W), Cathedral Park, Fund-Lead 3, and Fund-Lead 9. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. A K_D value for each sample location, excluding duplicates, was calculated and then averaged. The averaged RM9W K_D was then averaged with the calculated K_D values from Cathedral Park, Fund-Lead 3, and Fund-Lead 9 presented in Table E-2 of the SPDI Evaluation. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided. Table E-2 of the SPDI Evaluation additionally includes a Site-Wide sorption value that was not included in the average to prevent EPA-lead project areas from being weighted more heavily in the average K_D value.

5.13.6.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm:

- K_D = 233.431 L/kg

The Cathedral Park linear (K_D) isotherm:

- K_D = 2.81 log(L/kg) = 645.65 L/kg
- R^2 = 0.24
- n = 25

The Fund-Lead 3 linear (K_D) isotherm:

- K_D = 2.49 log(L/kg) = 309.03 L/kg
- R^2 = 0.75
- n = 15

The Fund-Lead 9 linear (K_D) isotherm:

- K_D = 2.49 log(L/kg) = 309.03 L/kg
- R^2 = 0.96
- n = 9

The average linear (K_D) isotherm used in CapSIM modeling:

- K_D = 374.29 L/kg

5.14 BEHP

5.14.1 Activated Carbon

The utilized sorption parameter for BEHP to GAC was sourced from Lin (2014). The sorption isotherms are presented in Table 2-2 of Pre-Final CDTM (Volume I, Appendix E).

5.14.1.1 Modeled Sorption Isotherm

Lin (2014) reports a non-linear isotherm, used in the CapSIM modeling:

- K_F = 11,300 (mg/g)/((mg/L)^(1/n)) = 3.57×10^5 (µg/kg)/((µg/L)^(1/n))
- 1/n = 1.5

5.14.2 Apatite

Literature describing BEHP sorption to apatite could not be found.

5.14.3 Bauxite

Literature describing BEHP sorption to bauxite could not be found.

5.14.4 Organoclay

Literature describing BEHP sorption to organoclay could not be found.

5.14.5 Sand and Sediment

5.14.5.1 Literature Review

Sorption for BEHP to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. A literature review was conducted, and two sources were identified that are applicable to the sorption of BEHP to sands and sediments: CLARC (2025), and EPA (2023).

5.14.5.2 Modeled Sorption Isotherm

EPA (2023) Table 38 reports a linear (K_{OC}) isotherm:

- K_{OC} = 111,123 L/kg = 5.05 log(L/kg)

The CLARC (2025) data table reports a linear (K_{OC}) isotherm:

- K_{OC} = 111,123 L/kg = 5.05 log(L/kg)

The value shared by the two sources was used in CapSIM modeling:

- K_{OC} = 5.05 log(L/kg)

5.15 BENZO(A)ANTHRACENE

5.15.1 Activated Carbon

The utilized sorption parameter for benzo(a)anthracene to GAC was the CapSIM default value. CapSIM documentation references two sources for isotherm parameters for PAHs: Walters & Luthy (1984) and Dobbs & Cohen (1980). The CapSIM default parameter for benzo(a)anthracene was sourced from Walters & Luthy (1984). This value was additionally utilized by GeoEngineers (2022).

5.15.1.1 Modeled Sorption Isotherm

The CapSIM default is a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 6.83 \times 10^6$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.50
- $R^2 = 0.67$

5.15.2 Sand

Sorption for benzo(a)anthracene to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Texas Commission on Environmental Quality's published Toxicity Values and Chemical – Physical Properties (TCEQ, 2019). This K_{OC} value is in agreement with the geometric mean in Table 38 of the Superfund Soil Screening Guidance (EPA, 2023).

5.15.3 Sediment

5.15.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for benzo(a)anthracene to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values were measured at adjacent PHSS project area Cathedral Park and presented in Table E-2 of the SPDI Evaluation. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.15.3.2 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm, used in CapSIM modeling:

- $K_D = 5.10$ log(L/kg) = 125892.54 L/kg
- n = 1

5.16 BENZO(A)PYRENE

5.16.1 Activated Carbon

The utilized sorption parameter for benzo(a)pyrene to GAC was the CapSIM default value. CapSIM documentation references two sources for isotherm parameters for PAHs: Walters & Luthy (1984) and Dobbs & Cohen (1980). The CapSIM default parameter for benzo(a)pyrene was sourced from Dobbs & Cohen (1980). This value was additionally utilized by GeoEngineers (2022).

5.16.1.1 Modeled Sorption Isotherm

The CapSIM default is a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 1.61 \times 10^6$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.44
- $R^2 = 0.90$

5.16.2 Sand and Sediment

Sorption for benzo(a)pyrene to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. The source identified to be applicable to the sorption of benzo(a)pyrene to sand and sediment is presented in Table D7-1 of the PHSS Remedial Investigation (RI)/Feasibility Study (FS) Appendix D, Supporting Information for Alternative Development. This K_{OC} value is in agreement with New Mexico Environment Department (2021) and Alaska Department of Environmental Conservation, Division of Spill Prevention and Response Contaminated Sites Program (2018).

5.17 BENZO(B)FLUORANTHENE

5.17.1 Activated Carbon

The utilized sorption parameter for benzo(b)fluoranthene to GAC was the CapSIM default value. CapSIM documentation references two sources for isotherm parameters for PAHs: Walters & Luthy (1984) and Dobbs & Cohen (1980). The CapSIM default parameter source for benzo(b)fluoranthene could not be verified from the listed sources. This value was additionally utilized by GeoEngineers (2022).

5.17.1.1 Modeled Sorption Isotherm

The CapSIM default is a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 4.42 \times 10^6$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.37

5.17.2 Sand and Sediment

Sorption for benzo(b)fluoranthene to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. The default K_{OC} value in CapSIM was utilized, which was sourced from Texas Commission on Environmental Quality's published Toxicity Values and Chemical – Physical Properties (TCEQ, 2019).

5.18 BENZO(E)PYRENE

5.18.1 Activated Carbon

The utilized sorption parameter for benzo(e)pyrene to GAC was sourced from Kupryianchyk et al. (2011). The sorption isotherms are presented in Table 1 of this report, and the optimum $LogK_{AC}$ with $n_{F,AC}$ of 0.82 was selected.

5.18.1.1 Modeled Sorption Isotherm

Kupryianchyk et al. (2011) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 8.4$; $K_F = 2.51\times10^8$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.82

5.18.2 Sand and Sediment

Sorption for benzo(e)pyrene to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. The default K_{OC} value in CapSIM was utilized, which uses the K_{OW} conversion $\log(K_{OC}) = 0.98\times\log(K_{OW})-0.32$. TCEQ (2023) is cited for the K_{OW} value and Schwarzenbach et al. (2017) is cited for the conversion method.

5.19 BENZO(G,H,I)PERYLENE

5.19.1 Activated Carbon

The utilized sorption parameter for benzo(g,h,i)perylene to GAC was the CapSIM default value. CapSIM documentation references two sources for isotherm parameters for PAHs: Walters & Luthy (1984) and Dobbs & Cohen (1980). The CapSIM default parameter for benzo(g,h,i)perylene was sourced from Dobbs & Cohen (1980). This value is similar to the value utilized by GeoEngineers (2022).

5.19.1.1 Modeled Sorption Isotherm

Dobbs & Cohen (1980) reports a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 10.7$ (mg/g)/((mg/L)^(1/n)) = 8.31×10^5 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.37
- $R^2 = 0.92$

5.19.2 Sand

Sorption for benzo(g,h,i)perylene to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. A literature review was conducted, and the source identified to be applicable to the sorption of benzo(g,h,i)perylene to Sand was in Table 7 of Alaska Department of Environmental Conservation, Division of Spill Prevention and Response Contaminated Sites Program (2018).

5.19.3 Sediment

5.19.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for benzo(g,h,i)perylene to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values were measured at adjacent PHSS project area Fund-Lead 3 and presented in Table E-2 of the SPDI Evaluation. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.19.3.2 Modeled Sorption Isotherm

The Fund-Lead 3 linear (K_D) isotherm, used in CapSIM modeling:

- K_D = 4.13 log(L/kg) = 13489.63 L/kg
- n = 1

5.20 BENZO(K)FLUORANTHENE

5.20.1 Activated Carbon

The utilized sorption parameter for benzo(k)fluoranthene to GAC was the CapSIM default value. CapSIM documentation references two sources for isotherm parameters for PAHs: Walters & Luthy (1984) and Dobbs & Cohen (1980). The CapSIM default parameter for benzo(k)fluoranthene appears to have been sourced from Dobbs & Cohen (1980). This is the same value as is reported in Lin (2014) and the value was additionally utilized by GeoEngineers (2022).

5.20.1.1 Modeled Sorption Isotherm

The CapSIM default is a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 3.53\times10^6$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.57

5.20.2 Sand and Sediment

Sorption for benzo(k)fluoranthene to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. The default K_{OC} value in CapSIM was utilized, which was sourced from Texas

Commission on Environmental Quality's published Toxicity Values and Chemical – Physical Properties (TCEQ, 2019).

5.21 CADMIUM

5.21.1 Activated Carbon

The utilized sorption parameter for cadmium to GAC was sourced from Erto et al. (2015). The sorption isotherms are presented in Table 2 of this report, and the Freundlich isotherm was selected as the coefficient determination (R^2) was the highest and standard error was the lowest for both modeled contaminants.

5.21.1.1 Modeled Sorption Isotherm

Erto et al. (2015) reports a non-linear isotherm, used in the CapSIM modeling:

- K_F = 0.096 (mmol/g)/((mmol/L)^(1/n)) = 4.62×10^3 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.667
- R^2 = 0.992

5.21.2 Sand

Sorption for cadmium to granular materials, such as capping Sand, uses the linear partition coefficient, K_D. A literature review was conducted, and two sources were identified that are applicable to the sorption of cadmium to Sand: CLARC (2025) and NJDEP (2014).

5.21.2.1 Modeled Sorption Isotherm

The CLARC (2025) data table reports a linear (K_D) isotherm:

- K_D = 6.7 L/kg

The NJDEP (2014) guidance document reports a linear (K_D) isotherm:

- K_D = 23 L/kg

An average of the two sources was used in CapSIM modeling:

- K_D = 14.85 L/kg

5.21.3 Sediment

Sorption for cadmium to sediment uses the linear partition coefficient, K_D. A literature review was conducted, and MFA (2009) was identified as applicable to the sorption of cadmium to sediment.

5.21.3.1 Modeled Sorption Isotherm

MFA (2009) Table 3-4 reports a linear (K_D) isotherm, used in CapSIM modeling:

- K_D = 4.7 log(L/kg) = 50,118 L/kg

5.22 CHLORDANES

5.22.1 Activated Carbon

The utilized sorption parameter for chlordanes to GAC was the CapSIM default value for chlordane (technical). CapSIM documentation references three sources for isotherm parameters for pesticides and other compounds: Dobbs & Cohen (1980), Speth & Miltner (1990), and Speth et al. (1988). Speth et al. (1988) could not be verified. The CapSIM default parameter for chlordanes appears to have been sourced from Dobbs & Cohen (1980). This is slightly lower, and therefore more conservative, than the reported isotherm in Lin (2014).

5.22.1.1 Modeled Sorption Isotherm

The CapSIM default is a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 1.77 \times 10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.38

5.22.2 Sand and Sediment

5.22.2.1 Literature Review

Sorption for chlordanes to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. A literature review was conducted, and four sources were identified to be applicable to the sorption of chlordanes to sands and sediments: Appendix D from Bureau of Habitat (2014), Table 1 of NJDEP (2014), the geometric mean from Table 38 of Superfund Soil Screening Guidance (EPA, 2023), and CLARC (2025). The log(K_{OC}) values were averaged and then utilized within CapSIM.

5.22.2.1 Modeled Sorption Isotherm

Bureau of Habitat (2014) Appendix D reports a linear (K_{OC}) isotherm:

- K_{OC} = 791189 L/kg = 5.90 log(L/kg)

NJDEP (2014) Table 1 reports a linear (K_{OC}) isotherm:

- K_{OC} = 120000 L/kg = 5.08 log(L/kg)

EPA (2023) Table 38 reports a linear (K_{OC}) isotherm:

- K_{OC} = 51310 L/kg = 4.71 log(L/kg)

The CLARC (2025) data table reports a linear (K_{OC}) isotherm:

- K_{OC} = 51310 L/kg = 4.71 log(L/kg)

The average log(K_{OC}) value from the four sources was used in CapSIM modeling:

- K_{OC} = 5.10 log(L/kg)

5.23 CHROMIUM

5.23.1 Activated Carbon

The utilized sorption parameter for chromium to GAC was the CapSIM default value for chromium (III). CapSIM documentation references McKay et al. (1985) for isotherm parameters for metals. The research presented in McKay et al. (1985) focused on the capacity of FILTRASORB 400 activated carbon to adsorb several contaminants from aqueous solutions for the purpose of removing contaminants from wastewater. The sorption parameters are presented in Table 3 of the study. McKay et al. (1985) additionally observed that the adsorption capacity of activated carbon shows a small particle size dependence possibly because the solute molecules cannot completely penetrate all the pores within the carbon particles.

5.23.1.1 Modeled Sorption Isotherm

The CapSIM default is a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 1.10 \times 10^5$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.44

5.23.2 Sand

Sorption for chromium to granular materials, such as capping Sand, uses the linear partition coefficient, K_D. A literature review was conducted, and CLARC (2025) was identified as applicable to the sorption of total chromium to Sand. CLARC (2025) reports K_D values for two oxidation states: Cr(III) and Cr(VI). The K_D value reported for total chromium is the same as for Cr(III) and higher than is reported for Cr(VI).

5.23.2.1 Modeled Sorption Isotherm

The CLARC (2025) data table reports a linear (K_D) isotherm, used in CapSIM modeling:

- K_D = 1000 L/kg

5.23.3 Sediment

Sorption for chromium to sediment uses the linear partition coefficient, K_D. A literature review was conducted, and MFA (2009) was identified as applicable to the sorption of chromium to sediment.

5.23.3.1 Modeled Sorption Isotherm

MFA (2009) Table 3-4 reports a linear (K_D) isotherm, used in CapSIM modeling:

- K_D = 4.6 log(L/kg) = 39,811 L/kg

5.24 CHRYSENE

5.24.1 Activated Carbon

The utilized sorption parameter for chrysene to GAC was the CapSIM default value. CapSIM documentation references two sources for isotherm parameters for PAHs: Walters & Luthy (1984) and Dobbs & Cohen (1980). The CapSIM default parameter for chrysene appears to have been sourced from Walters & Luthy (1984). This value was additionally utilized by GeoEngineers (2022).

5.24.1.1 Modeled Sorption Isotherm

The CapSIM default is a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 3.03 \times 10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.458
- $R^2 = 0.62$

5.24.2 Sand

Sorption for chrysene to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Texas Commission on Environmental Quality's published Toxicity Values and Chemical – Physical Properties (TCEQ, 2019).

5.24.3 Sediment

5.24.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for chrysene to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area Cathedral Park and presented in Table E-2 of the SPDI Evaluation. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.24.3.1 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm, used in CapSIM modeling:

- $K_D = 5.39$ log(L/kg) = 245470.89 L/kg
- $R^2 = 0.56$
- n = 5

5.25 COPPER

5.25.1 Activated Carbon

The utilized sorption parameter for copper to GAC was sourced from Patnukao et al. (2008). The research presented in Patnukao et al. (2008) focused on the effects of pH, contact time, initial concentration and temperature. The sorption isotherms are presented in Table 4 of this study. The Langmuir isotherm is used as it fits the experimental data better than the Freundlich isotherm. Notable experimental assumptions and processes include:

- Eucalyptus bark was sourced from Advance Agro Co., Ltd, Prachinburi Province, Thailand and then activated and crushed into PAC (size range of 0.045-0.150mm).
- Solution pH was 5, lower than the expected pH at the site (approximately 6.4).
- Temperature was 25.0 ± 1°C, higher than the expected temperature at the site (averaging between 4°C and 22°C).

Patnukao et al. (2008) notes that at pH values above 6 the electrostatic repulsion between cations and the positively charged surface is reduced, promoting a higher adsorption, however, insoluble hydrolyzed species could also form and lead to misunderstanding the adsorption capacity of the sorbent. Additionally, higher temperatures were found to increase the adsorption capacity.

5.25.1.1 Modeled Sorption Isotherm

Patnukao et al. (2008) reports a non-linear isotherm, used in the CapSIM modeling:

- q_m = 0.45 mmol/g = 2.86×10^{7} µg/kg
- b = 0.19 L/mmol = 2.99×10^{-6} L/µg
- R^2 = 0.9911

5.25.2 Sand

Sorption for copper to granular materials, such as capping Sand, uses the linear partition coefficient, K_D. A literature review was conducted, and two sources were identified that are applicable to the sorption of copper to Sand: CLARC (2025) and NJDEP (2014).

5.25.2.1 Modeled Sorption Isotherm

The CLARC (2025) data table reports a linear (K_D) isotherm:

- K_D = 22 L/kg

The NJDEP (2014) guidance document reports a linear (K_D) isotherm:

- K_D = 430 L/kg

An average of the two sources was used in CapSIM modeling:

- K_D = 226 L/kg

5.25.3 Sediment

5.25.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, the utilized sorption parameter (K_D) for copper to sediment, 31622.8 L/kg, was based on the value used in the sediment cap modeling for the Zidell Waterfront Property (MFA, 2009), on the west side of the Willamette River upstream of the PHSS. Project Area-specific partitioning values were measured at adjacent PHSS project areas RM9W, Cathedral Park, Fund-Lead 3, and Fund-Lead 9. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. A K_D value for each sample location was calculated. The K_D value from sample T15 and its duplicate was excluded from the average K_D calculation along with the T9 sample duplicate. At T15, the measured Copper concentrations in sediment (450 mg/kg and 140 mg/kg) are very high compared to the other samples taken at RM9W (36-98 mg/kg) and the transition zone water concentration is non-detect at a lab reporting limit of 20 µg/L. Copper was detected in transition zone water at two other sample locations where sediment concentrations lower than those at T15 were observed, T14 (53 mg/kg) and T18 (98 mg/kg). The resulting K_D values calculated for T15 and its duplicate, 34615.4 and 10769.2 respectively, are between 2.1 and 38.9 times higher than the K_D values calculated for the other sample locations.

The averaged RM9W K_D was then averaged with the calculated K_D values from Cathedral Park, Fund-Lead 3, and Fund-Lead 9 presented in Table E-2 of the SPDI Evaluation. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided. Table E-2 of the SPDI Evaluation additionally includes a Project Area-Wide sorption value that was not included in the average to prevent EPA-lead project areas from being weighted more heavily in the average K_D value.

5.25.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm:

- K_D = 2885.483 L/kg

The Cathedral Park linear (K_D) isotherm:

- K_D = 5.00 log(L/kg) = 100000.00 L/kg
- R^2 = 0.76
- n = 11

The Fund-Lead 3 linear (K_D) isotherm:

- K_D = 4.67 log(L/kg) = 46773.51 L/kg
- R^2 = 0.37
- n = 13

The Fund-Lead 9 linear (K_D) isotherm:

- K_D = 4.94 log(L/kg) = 87096.36 L/kg
- R^2 = 0.98

- n = 7

The average linear (K_D) isotherm used in CapSIM modeling:

- K_D = 59,189 L/kg

5.26 DDD

5.26.1 Activated Carbon

The utilized sorption parameter for DDD to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2.

5.26.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 8.30$; $K_F = 2.00\times10^8$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.73
- $R^2 = 0.95$

5.26.2 Sand

5.26.2.1 Literature Review

Sorption for DDD to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material.
A literature review was conducted, and six sources were identified to be applicable to the sorption of DDD to sands and sediments: Table 1 of NJDEP(2014), Table 39 of Superfund Soil Screening Guidance (EPA, 2023), CLARC (2025), the CapSIM default value sourced from TCEQ (2023), Table C-6-2 of AECOM (2017), and Table 3-7 of the Lower Passaic River Contaminant Fate and Transport Model (The Louis Berger Group et al., 2014). To encapsulate the range of found literature values, the average log(K_{OC}) was utilized within CapSIM.

5.26.2.2 Modeled Sorption Isotherm

NJDEP (2014) Table 1 reports a linear (K_{OC}) isotherm:

- K_{OC} = 1.00E+06 L/kg = 6.00 log(L/kg)

EPA (2023) Table 39 reports a linear (K_{OC}) isotherm:

- K_{OC} = 1.00E+06 L/kg = 6.00 log(L/kg)

The CLARC (2025) data table reports a linear (K_{OC}) isotherm:

- K_{OC} = 45800 L/kg = 4.66 log(L/kg)

The CapSIM default is a linear (K_{OC}) isotherm:

- K_{OC} = 4.93 log(L/kg)

AECOM (2017) Table C-6-2 reports a linear (K_{OC}) isotherm:

- K_{OC} = 117500 cm^3/g = 5.07 log(L/kg)

The Louis Berger Group et al. (2014) Table 3-7 reports a linear (K_{OC}) isotherm:

- K_{OC} = 6.42 log(L/kg)

The average log(K_{OC}) value from the four sources was used in CapSIM modeling:

- K_{OC} = 5.51 log(L/kg)

5.26.3 Sediment

5.26.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for DDD to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project areas Cathedral Park, Fund-Lead 3, and Fund-Lead 9. The calculated K_D values from Cathedral Park, Fund-Lead 3, and Fund-Lead 9 presented in Table E-2 of the SPDI Evaluation were averaged. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.26.3.2 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm:

- K_D = 4.68 log(L/kg) = 47863.01 L/kg L/kg
- R^2 = 0.56
- n = 19

The Fund-Lead 3 linear (K_D) isotherm:

- K_D = 3.86 log(L/kg) = 7244.36 L/kg
- R^2 = 0.45
- n = 15

The Fund-Lead 9 linear (K_D) isotherm:

- K_D = 3.80 log(L/kg) = 6309.57 L/kg
- R^2 = 0.59
- n = 7

The average linear (K_D) isotherm used in CapSIM modeling:

- K_D = 20472.31 L/kg

5.27 DDE

5.27.1 Activated Carbon

The utilized sorption parameter for DDE to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2. This value is higher than the reported isotherm in Lin (2014).

5.27.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 8.50$; $K_F = 3.16\times10^8$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.69
- $R^2 = 0.95$

5.27.2 Sand

5.27.2.1 Literature Review

Sorption for DDE to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material.

A literature review was conducted, and five sources were identified to be applicable to the sorption of DDD to sands and sediments: Table 1 of NJDEP(2014), Table 39 of Superfund Soil Screening Guidance (EPA, 2023), CLARC (2025), the CapSIM default value sourced from TCEQ (2023), and Table 3-7 of the Lower Passaic River Contaminant Fate and Transport Model (The Louis Berger Group et al., 2014). To encapsulate the range of found literature values, the average log(K_{OC}) was utilized within CapSIM.

5.27.2.2 Modeled Sorption Isotherm

NJDEP (2014) Table 1 reports a linear (K_{OC}) isotherm:

- K_{OC} = 4.47E+06 L/kg = 6.65 log(L/kg)

EPA (2023) Table 39 reports a linear (K_{OC}) isotherm:

- K_{OC} = 4.47E+06 L/kg = 6.65 log(L/kg)

The CLARC (2025) data table reports a linear (K_{OC}) isotherm:

- K_{OC} = 86405 L/kg = 4.94 log(L/kg)

The CapSIM default is a linear (K_{OC}) isotherm:

- K_{OC} = 2.7 log(L/kg)

The Louis Berger Group et al. (2014) Table 3-7 reports a linear (K_{OC}) isotherm:

- K_{OC} = 7.26 log(L/kg)

The average log(K_{OC}) value from the five sources was used in CapSIM modeling:

- K_{OC} = 5.64 log(L/kg)

5.27.3 Sediment

5.27.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for DDE to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project areas Cathedral Park, Fund-Lead 3, and Fund-Lead 9. The calculated K_D values from Cathedral Park, Fund-Lead 3, and Fund-Lead 9 presented in Table E-2 of the SPDI Evaluation were averaged. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.27.3.2 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm:

- K_D = 4.77 log(L/kg) = 58884.37 L/kg L/kg
- R^2 = 0.70
- n = 6

The Fund-Lead 3 linear (K_D) isotherm:

- K_D = 4.78 log(L/kg) = 60255.96 L/kg
- R^2 = 0.33
- n = 6

The Fund-Lead 9 linear (K_D) isotherm:

- K_D = 4.88 log(L/kg) = 75857.76 L/kg
- n = 1

The average linear (K_D) isotherm used in CapSIM modeling:

- K_D = 64999.36 L/kg

5.28 DDT

5.28.1 Activated Carbon

The utilized sorption parameter for DDT to GAC was the CapSIM default value. CapSIM documentation references three sources for isotherm parameters for pesticides and other compounds: Dobbs & Cohen (1980), Speth & Miltner (1990), and Speth et al. (1988). Speth et al.

(1988) could not be verified. The CapSIM default parameter for DDT appears to have been sourced from Dobbs & Cohen (1980). This is consistent with the reported isotherm in Lin (2014).

5.28.1.1 Modeled Sorption Isotherm

The CapSIM default is a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 1.02 \times 10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.50
- $R^2 = 0.89$

5.28.2 Sand

Sorption for DDT to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Texas Commission on Environmental Quality's published Chemical/Physical Properties Table accompanying the Texas Risk Reduction Program (TRRP) Rule (TCEQ, 2023).

5.28.3 Sediment

5.28.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for DDT to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the DDT organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project areas Cathedral Park and Fund-Lead 3. The calculated K_D values from Cathedral Park and Fund-Lead 3 presented in Table E-2 of the SPDI Evaluation were averaged. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.28.3.2 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm:

- K_D = 5.61 log(L/kg) = 407380.28 L/kg L/kg
- $R^2 = 0.40$
- n = 4

The Fund-Lead 3 linear (K_D) isotherm:

- K_D = 4.19 log(L/kg) = 15488.17 L/kg
- $R^2 = 0.98$
- n = 2

The average linear (K_D) isotherm used in CapSIM modeling:

- K_D = 211434.22 L/kg

5.29 DIBENZ(A,H)ANTHRACENE

5.29.1 Activated Carbon

The utilized sorption parameter for benzo(b)fluoranthene to GAC was the CapSIM default value. CapSIM documentation references two sources for isotherm parameters for PAHs: Walters & Luthy (1984) and Dobbs & Cohen (1980). The CapSIM default parameter source for dibenz(a,h)fluoranthene could not be verified from the listed sources. This value was additionally utilized by GeoEngineers (2022).

5.29.1.1 Modeled Sorption Isotherm

The CapSIM default is a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 3.90\times10^5$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.75

5.29.2 Sand and Sediment

Sorption for dibenz(a,h)anthracene to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. The default K_{OC} value in CapSIM was utilized, which was sourced from Texas Commission on Environmental Quality's published Toxicity Values and Chemical – Physical Properties (TCEQ, 2019). This K_{OC} value is slightly higher than the geometric mean in Table 38 of the Superfund Soil Screening Guidance (EPA, 2023): 6.25 log(L/kg).

5.30 DIELDRIN

5.30.1 Activated Carbon

The utilized sorption parameter for dieldrin to GAC was sourced from Lin (2014). The Freundlich sorption isotherms are presented in Table 2-2 of Pre-Final CDTM (Volume I, Appendix E).

5.30.1.1 Modeled Sorption Isotherm

Lin (2014) reports a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 606$ (mg/g)/((mg/L)^(1/n)) = 1.79×10^7 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.51

5.30.2 Sand and Sediment

5.30.2.1 Literature Review

Sorption for dieldrin to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. A literature review was conducted, and four sources were identified to be applicable to the sorption of dieldrin to sands and sediments: Appendix D from Bureau of Habitat (2014), Table 1 of NJDEP (2014), the geometric mean from Table 38 of Superfund Soil Screening Guidance (EPA, 2023),

and CLARC (2025). To encapsulate the range of found literature values, the average log(K_{OC}) was utilized within CapSIM.

5.30.2.2 Modeled Sorption Isotherm

Bureau of Habitat (2014) Appendix D reports a linear (K_{OC}) isotherm:

- K_{OC} = 161881 L/kg = 5.21 log(L/kg)

EPA (2023) Table 38 reports a linear (K_{OC}) isotherm:

- K_{OC} = 25546 L/kg = 4.41 log(L/kg)

NJDEP (2014) Table 1 reports a linear (K_{OC}) isotherm:

- K_{OC} = 21400 L/kg = 4.33 log(L/kg)

The CLARC (2025) data table reports a linear (K_{OC}) isotherm:

- K_{OC} = 25546 L/kg = 4.41 log(L/kg)

The average log(K_{OC}) value from the four sources was used in CapSIM modeling:

- K_{OC} = 4.59 log(L/kg)

5.31 DIESEL

5.31.1 Activated Carbon

Limited literature is available investigating the sorption of diesel to activated carbon. In the Draft 50% RD CDTM, the utilized sorption parameter for diesel to GAC was sourced from Adeyoye (1999). The research presented in Adeyoye (1999) focused on treating hydrocarbons contaminated groundwater. The sorption isotherm is presented in Table 3.1 of this paper. Notable experimental assumptions and processes include:

- Analyzed aged total petroleum hydrocarbon (TPH)
- The untreated GAC was FILTRASORB 400, sourced from Calgon Carbon
- Solution pH was 6.8, similar to the expected pH at the project area (approximately 6.4)

Additional literature review was conducted, and two additional sources were identified that are applicable to the sorption of diesel to GAC: Giustra and Di Bella (2017) and Ayotamuno (2006). The experimental amount adsorbed (q; µg/kg) was plotted against the equilibrium concentration (C; µg/L) for all three studies (Figure C-4 below).

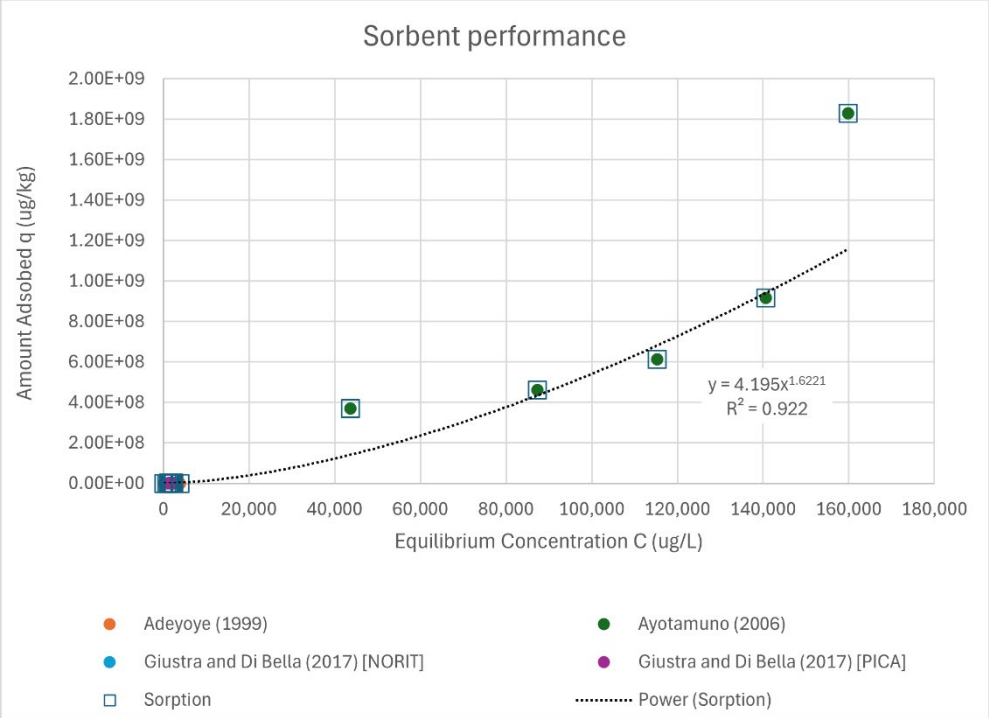

Figure C-4. GAC sorption of Diesel

The log of the experimental amount adsorbed was additionally plotted against the log of the equilibrium concentration to aide in visualization for the lower concentration experimental data (Figure C-5 below).

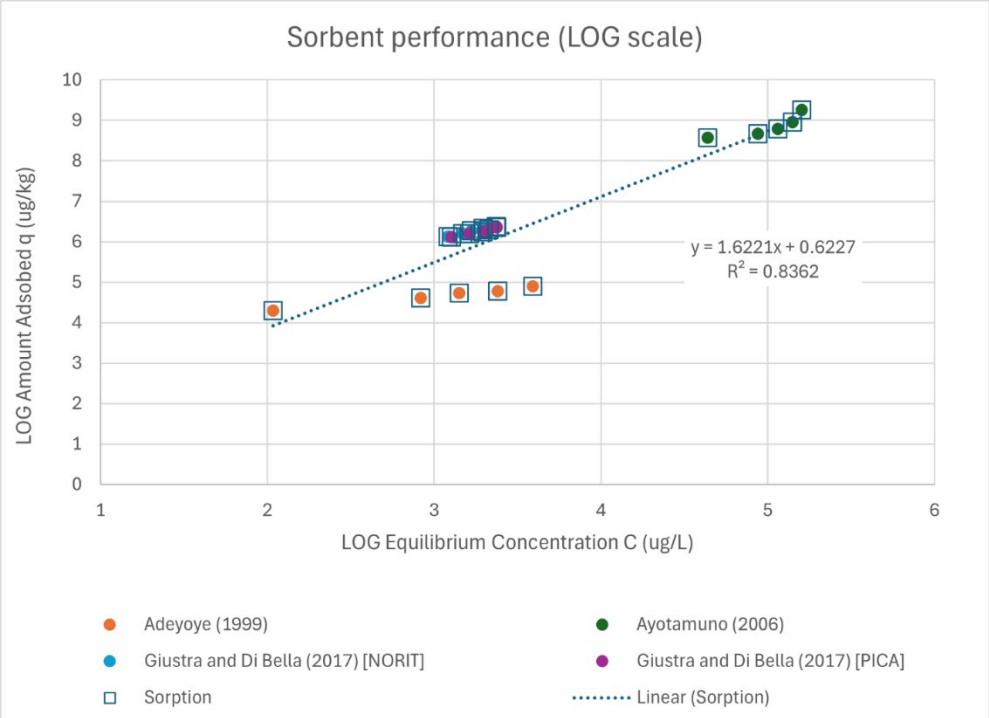

Figure C-5. GAC sorption of Diesel – log scale

Giustra and Di Bella (2017) utilized two different commercial samples of GAC: PIC-Anhydro S23 and NORIT GAC 830W. The study analyzed sorption at a pH of 7.8, higher than expected conditions in the sediment cap. Ayotamuno (2006) studied the performance of GAC compared to powdered activated carbon (PAC) at a pH of 5.5, lower than expected conditions in the sediment cap, and did not specify the source of the studied materials, however, the paper cites Norit and Ultra Carbon as common trade names. The experimental data from the three studies represent different sediment pH and capping material combinations, the log scale of the sorbent performance (Figure C-5) shows distinct groupings that are not in clear agreement, and all values result in weaker adsorption than expected.

Aged diesel is more likely to be the lower solubility constituents, as the lighter, more soluble, and more bioavailable compounds have diminished over extended periods of time in an aqueous environment. That process and the representative compounds within diesel, including decane hexadecane, and naphthalene, would result in a higher expected sorption coefficient than is reported in the literature referenced above. Therefore, diesel sorption to GAC was modeled using the linear organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the GAC.

5.31.2 Sand

Sorption for diesel to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. A literature review was conducted, and the source identified to be applicable to the sorption of diesel to Sand was Table 1 of California Department of Toxic Substances Control (2009).

5.31.3 Sediment

5.31.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for diesel to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area Cathedral Park and presented in Table E-2 of the SPDI Evaluation. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.31.3.1 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm, used in CapSIM modeling:

- K_D = 3.34 log(L/kg) = 2187.76 L/kg
- n = 1

5.32 FLUORANTHENE

5.32.1 Activated Carbon

The utilized sorption parameter for fluoranthene to GAC was sourced from Walters & Luthy (1984). The sorption isotherms are presented in Table III of this study. The Langmuir isotherm was determined by the researchers to be the most useful of the evaluated equations for representing

the data. However, the Langmuir equation was not capable of describing the adsorption over the entire concentration range. The experimental data was reasonably fit by the Freundlich isotherm and was therefore selected. This value is lower, and therefore more conservative, than the reported isotherm in Gomez-Eyles et al. (2013) and slightly higher than the value utilized by GeoEngineers (2022).

5.32.1.1 Modeled Sorption Isotherm

Walters & Luthy (1984) reports a non-linear isotherm, used in the CapSIM modeling:

- K_F = 242 (mg/g)/((mg/L)^(1/n)) = 2.77×10^7 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.314
- R^2 = 0.81

5.32.2 Sand

Sorption for fluoranthene to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Texas Commission on Environmental Quality's published Toxicity Values and Chemical – Physical Properties (TCEQ, 2019). This K_{OC} value is in agreement with the geometric mean in Table 38 of the Superfund Soil Screening Guidance (EPA, 2023).

5.32.3 Sediment

5.32.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for fluoranthene to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area Cathedral Park and presented in Table E-2 of the SPDI Evaluation. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.32.3.2 Modeled Sorption Isotherm

The average Cathedral Park linear (K_D) isotherm, used in CapSIM modeling:

- K_D = 4.77 log(L/kg) = 58884.37 L/kg
- R^2 = 0.71
- n = 9

5.33 FLUORENE

5.33.1 Activated Carbon

The utilized sorption parameter for fluorene to GAC was sourced from Walters & Luthy (1984). The sorption isotherms are presented in Table III of this study. The Langmuir isotherm was

determined by the researchers to be the most useful of the evaluated equations for representing the data. However, the Langmuir equation was not capable of describing the adsorption over the entire concentration range. The experimental data was reasonably fit by the Freundlich isotherm and was therefore selected. This value was additionally utilized by GeoEngineers (2022).

5.33.1.1 Modeled Sorption Isotherm

Walters & Luthy (1984) reports a non-linear isotherm, used in the CapSIM modeling:

- K_F = 674 (mg/g)/((mg/L)^(1/n)) = 1.04×10^7 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.604
- R^2 = 0.90

5.33.2 Sand

Sorption for fluorene to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. A literature review was conducted, and the source identified to be applicable to the sorption of fluorene to sand and sediment was Table B-2 of New Mexico Environment Department (2021). This K_{OC} value is in agreement with Alaska Department of Environmental Conservation, Division of Spill Prevention and Response Contaminated Sites Program (2018).

5.33.3 Sediment

5.33.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for fluorene to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area Cathedral Park and presented in Table E-2 of the SPDI Evaluation. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.33.3.1 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm, used in CapSIM modeling:

- K_D = 3.56 log(L/kg) = 3630.78 L/kg
- R^2 = 0.98
- n = 6

5.34 INDENO(1,2,3-CD)PYRENE

5.34.1 Activated Carbon

The utilized sorption parameter for indendo(1,2,3-cd)pyrene to GAC was sourced from Kupryianchyk et al. (2011). The sorption isotherms are presented in Table 1 of this report, and the optimum $LogK_{AC}$ with $n_{F,AC}$ of 0.82 was selected. This value is slightly higher than the value utilized by GeoEngineers (2022).

5.34.1.1 Modeled Sorption Isotherm

Kupryianchyk et al. (2011) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 8.3$; $K_F = 2.00\times10^8$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.82

5.34.2 Sand and Sediment

Sorption for indeno(1,2,3-cd)pyrene to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. The default K_{OC} value in CapSIM was utilized, which was sourced from Texas Commission on Environmental Quality's published Toxicity Values and Chemical – Physical Properties (TCEQ, 2019).

5.35 LEAD

5.35.1 Activated Carbon

The utilized sorption parameter for lead to GAC was sourced from Patnukao et al. (2008). The research presented in Patnukao et al. (2008) focused on the effects of pH, contact time, initial concentration and temperature. The sorption isotherms are presented in Table 4 of this study. The Langmuir isotherm is used as it fits the experimental data better than the Freundlich isotherm. Notable experimental assumptions and processes include:

- Eucalyptus bark was sourced from Advance Agro Co., Ltd, Prachinburi Province, Thailand and then activated and crushed into PAC (size range of 0.045-0.150mm).
- Solution pH was 5, lower than the expected pH at the site (approximately 6.4).
- Temperature was 25.0 ± 1°C, higher than the expected temperature at the site (averaging between 4°C and 22°C).

Patnukao et al. (2008) notes that at pH values above 6 the electrostatic repulsion between cations and the positively charged surface is reduced, promoting a higher adsorption, however, insoluble hydrolyzed species could also form and lead to misunderstanding the adsorption capacity of the sorbent. Additionally, higher temperatures were found to increase the adsorption capacity.

5.35.1.1 Modeled Sorption Isotherm

Patnukao et al. (2008) reports a non-linear isotherm, used in the CapSIM modeling:

- $q_m = 0.55$ mmol/g = 1.14×10^9 µg/kg
- b = 0.23 L/mmol = 1.11×10^{-6} L/µg
- $R^2 = 0.9969$

5.35.2 Sand

Sorption for lead to granular materials, such as capping Sand, uses the linear partition coefficient, K_D. A literature review was conducted, and two sources were identified that are applicable to the sorption of lead to Sand: CLARC (2025) and NJDEP (2014).

5.35.2.1 Modeled Sorption Isotherm

The CLARC (2025) data table reports a linear (K_D) isotherm:

- K_D = 10000 L/kg

The NJDEP (2014) guidance document reports a linear (K_D) isotherm:

- K_D = 900 L/kg

An average of the two sources was used in CapSIM modeling:

- K_D = 5450 L/kg

5.35.3 Sediment

Sorption for lead to sediment uses the linear partition coefficient, K_D. A literature review was conducted, and MFA (2009) was identified as applicable to the sorption of lead to sediment.

5.35.3.1 Modeled Sorption Isotherm

MFA (2009) Table 3-4 reports a linear (K_D) isotherm, used in CapSIM modeling:

- K_D = 4.3 log(L/kg) = 19,953 L/kg

5.36 LINDANE

5.36.1 Activated Carbon

The utilized sorption parameter for lindane to GAC was sourced from Lin (2014). The sorption isotherms are presented in Table 2-2 of Pre-Final CDTM (Volume I, Appendix E).

5.36.1.1 Modeled Sorption Isotherm

Lin (2014) reports a non-linear isotherm, used in the CapSIM modeling:

- K_F = 285 (mg/g)/((mg/L)^(1/n)) = 1.46×10^7 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.43

5.36.2 Sand and Sediment

5.36.2.1 Literature Review

Sorption for lindane to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. A literature review was conducted, and five sources were identified to be applicable to the sorption

of lindane to sands and sediments: Appendix D from Bureau of Habitat (2014), Table 1 of NJDEP (2014), the geometric mean from Table 38 of Superfund Soil Screening Guidance (EPA, 2023), TCEQ (2023), and the EPA National Primary Drinking Water Regulations Technical Factsheet on Lindane (EPA, n.d.). To encapsulate the range of found literature values, the average log(K_{OC}) was utilized within CapSIM.

5.36.2.2 Modeled Sorption Isotherm

Bureau of Habitat (2014) Appendix D reports a linear (K_{OC}) isotherm:

- K_{OC} = 4082 L/kg = 3.61 log(L/kg)

NJDEP (2014) Table 1 reports a linear (K_{OC}) isotherm:

- K_{OC} = 1070 L/kg = 3.03 log(L/kg)

EPA (2023) Table 38 reports a linear (K_{OC}) isotherm:

- K_{OC} = 1352 L/kg = 3.13 log(L/kg)

The TCEQ (2023) data table reports a linear (K_{OC}) isotherm:

- K_{OC} = 3.04 log(L/kg)

The EPA (n.d.) factsheet reports a linear (K_{OC}) isotherm:

- K_{OC} = 1081 = 3.03 log(L/kg)

The average log(K_{OC}) value from the five sources was used in CapSIM modeling:

- K_{OC} = 3.17 log(L/kg)

5.37 MANGANESE

5.37.1 Activated Carbon

A literature review was conducted, and two sources were identified that are applicable to the sorption of manganese to GAC: bin Jusoh et al. (2005) and Tran et al. (2018). The research presented in bin Jusoh et al. (2005) focused on the effectiveness of GAC in removing iron and manganese for the palatability of drinking water. The Freundlich sorption isotherms are presented in Table 1 of this study. Langmuir isotherms are additionally presented in Table 2 of this study, however, in a non-standard form. bin Jusoh et al. (2005) observed that activated carbon has a higher adsorption capacity for Fe(II) compared to Mn(II) and concluded it may relate to electronegativity and ionic radius; Fe(II) is more electronegative and has a smaller ionic radius than Mn(II). Notable experimental assumptions and processes include:

- Analyzed Mn(II)

- The coconut shell GAC was supplied by local manufacturer Kekwa Indah Sdn Bhd in Nilai, Negeri Sembilan, Malaysia. The crushed carbon utilized was between sieve sizes of 850 mm and 1000 mm.
- Temperature was 30°C, higher than the expected temperature at the site (averaging between 4°C and 22°C).

The research presented in Tran et al. (2018) focused on characterizing the properties and functional groups of acid-modified GAC. Mn(II) removal was studied under different experimental conditions including pH, temperature, initial contaminant concentration, and adsorbent dose. The sorption isotherms for un-modified GAC (R-GAC) are presented in Table 4 of this study as a control, and the Freundlich isotherm was selected for comparison with the other applicable source. Tran et al. (2018) observed that nitric acid treatment greatly enhanced the adsorption performance of modified GAC (M-GAC). The higher adsorption capacity was determined to be related mainly to the development of new carboxylic groups (-COOH) on the GAC surface, ultimately enabling the formation of surface complexes between Mn(II) ions and functional groups. Notable experimental assumptions and processes include:

- Analyzed Mn(II)
- The adsorbent used was NORIT® GAC 1240 acquired from Norit Americas Inc., USA.
- Solution pH was 6.0, slightly lower than the expected pH at the site (approximately 6.4).
- Temperature was 25°C, higher than the expected temperature at the site (averaging between 4°C and 22°C).

5.37.1.1 Modeled Sorption Isotherm

bin Jusoh et al. (2005) reports a non-linear isotherm:

- K_F = 2.3372 (mg/g)/((mg/L)^(1/n)) = 1.32×10^6 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.0824
- R^2 = 0.9227

Tran et al. (2018) reports a non-linear isotherm:

- K_F = 0.33 (mg/g)/((mg/L)^(1/n)) = 1.66×10^4 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.433
- R^2 = 0.9379

An average of the two sources was used in CapSIM modeling:

- K_F = 6.70×10^5 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.258

5.37.2 Sand

Sorption for manganese to granular materials, such as capping Sand, uses the linear partition coefficient, K_D. A literature review was conducted, and two sources were identified that are applicable to the sorption of manganese to Sand: CLARC (2025) and NJDEP (2014).

5.37.2.1 Modeled Sorption Isotherm

The CLARC (2025) data table reports a linear (K_D) isotherm:

- K_D = 65 L/kg

The NJDEP (2014) guidance document reports a linear (K_D) isotherm:

- K_D = 65 L/kg

An average of the two sources was used in CapSIM modeling:

- K_D = 65 L/kg

5.37.3 Sediment

5.37.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, the utilized sorption parameter (K_D) for manganese to sediment, 65.0 L/kg, was the average of the sorption values available in CLARC (2025) and NJDEP (2014). This is the value that is being utilized as the K_D for manganese to Sand. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.37.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- K_D = 70.22 L/kg

5.38 MERCURY

5.38.1 Activated Carbon

The utilized sorption parameter for mercury to GAC was the CapSIM default value. CapSIM documentation references McKay et al. (1985) for isotherm parameters for metals. The research presented in McKay et al. (1985) focused on the capacity of FILTRASORB 400 activated carbon to adsorb several contaminants from aqueous solutions for the purpose of removing contaminants from wastewater. The sorption parameters are presented in Table 3 of the study. McKay et al. (1985) additionally observed that the adsorption capacity of activated carbon shows a small particle size dependence possibly because the solute molecules cannot completely penetrate all the pores within the carbon particles.

5.38.1.1 Modeled Sorption Isotherm

The CapSIM default is a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 8.34 \times 10^5$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.46

5.38.2 Sand

Sorption for mercury to granular materials, such as capping Sand, uses the linear partition coefficient, K_D. A literature review was conducted, and two sources were identified that are applicable to the sorption of mercury to Sand: CLARC (2025) and NJDEP (2014).

5.38.2.1 Modeled Sorption Isotherm

The CLARC (2025) data table reports a linear (K_D) isotherm:

- K_D = 52 L/kg

The NJDEP (2014) guidance document reports a linear (K_D) isotherm:

- K_D = 0.2 L/kg

An average of the two sources was used in CapSIM modeling:

- K_D = 26.1 L/kg

5.38.3 Sediment

Sorption for mercury to sediment uses the linear partition coefficient, K_D. A literature review was conducted, and MFA (2009) was identified as applicable to the sorption of mercury to sediment.

5.38.3.1 Modeled Sorption Isotherm

MFA (2009) Table 3-4 reports a linear (K_D) isotherm, used in CapSIM modeling:

- K_D = 3.1 log(L/kg) = 1,259 L/kg

5.39 NAPHTHALENE

5.39.1 Activated Carbon

The utilized sorption parameter for naphthalene to GAC was sourced from Walters & Luthy (1984). The sorption isotherms are presented in Table III of this study. The Langmuir isotherm was determined by the researchers to be the most useful of the evaluated equations for representing the data. However, the Langmuir equation was not capable of describing the adsorption over the entire concentration range. The experimental data was reasonably fit by the Freundlich isotherm and was therefore selected. This value was additionally utilized by GeoEngineers (2022) and is slightly lower and therefore more conservative, than the reported isotherm in Table 5.7 of Chattopadhyay (2011).

5.39.1.1 Modeled Sorption Isotherm

Walters & Luthy (1984) reports a non-linear isotherm, used in the CapSIM modeling:

- K_F = 277 (mg/g)/((mg/L)^(1/n)) = 1.42×10^7 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.43
- R^2 = 0.87

5.39.2 Sand and Sediment

Sorption for naphthalene to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. A literature review was conducted, and the source identified to be applicable to the sorption of naphthalene to Sand and Sediments was Table 4 of Center for Environmental & Human Toxicology, University of Florida (2005). This K_{OC} value is in agreement with the value presented in Table 7 of Bureau of Habitat (2014).

5.40 PCB-1

5.40.1 Activated Carbon

The utilized sorption parameter for PCB-1 to GAC was sourced from Chattopadhyay (2011). The research presented in Chattopadhyay (2011) focused on granular materials as direct amendments to conventional caps including; granular activated carbon (GAC), iron (Fe)/palladium (Pd) amended GAC, alumina pillared clay, rice husk char, and organically modified clays. This report was prepared for the EPA. The sorption isotherms adapted from Sharma (2008) are presented in Table 2.3 of this study. The original study utilized activated carbon created from coconut shells. Chattopadhyay (2011) observed that PCB partitioning to activated carbon is strongly related to K_{OW} and influenced by the total number of chlorines and the number of chlorines in the ortho position.

5.40.1.1 Modeled Sorption Isotherm

Chattopadhyay (2011) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 7.90$; $K_F = 7.94 \times 10^7$ (µg/kg)/((µg/L)^(1/n))
- $1/n = 0.34$

5.40.2 Sand

Sorption for PCB-1 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.40.3 Sediment

5.40.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-1 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.40.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- K_D = 1558.74 L/kg

5.41 PCB-15

5.41.1 Activated Carbon

The utilized sorption parameter for PCB-15 to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2. In this study, PCB-15 was coeluted with PCB-17.

5.41.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F)$ = 8.60 ; $K_F = 3.98 \times 10^8$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 1.01
- R^2 = 0.98

5.41.2 Sand

Sorption for PCB-15 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.41.3 Sediment

5.41.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-15 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.41.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- K_D = 24901.577 L/kg

5.42 PCB-31

5.42.1 Activated Carbon

The utilized sorption parameter for PCB-31 to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2.

5.42.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 8.90$; $K_F = 7.94 \times 10^8$ (µg/kg)/((µg/L)^(1/n))
- $1/n = 0.99$
- $R^2 = 0.98$

5.42.2 Sand

Sorption for PCB-31 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.42.3 Sediment

5.42.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-31 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.42.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- $K_D = 413537.83$ L/kg

5.43 PCB-44

5.43.1 Activated Carbon

The utilized sorption parameter for PCB-44 to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2.

5.43.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 8.60$; $K_F = 3.98 \times 10^8$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.92
- $R^2 = 0.99$

5.43.2 Sand

Sorption for PCB-44 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.43.3 Sediment

5.43.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-44 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. The results for PCB-44 was reported with coeluters (PCB-44/47/65). A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.43.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- $K_D = 987325.54$ L/kg

5.44 PCB-99

5.44.1 Activated Carbon

The utilized sorption parameter for PCB-99 to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2.

5.44.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 7.70$; $K_F = 5.01 \times 10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.71
- $R^2 = 0.98$

5.44.2 Sand

Sorption for PCB-99 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.44.3 Sediment

5.44.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-99 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. The results for PCB-99 was reported with coeluters (PCB-83/99). A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.44.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- K_D = 452549.15 L/kg

5.45 PCB-141

5.45.1 Activated Carbon

The utilized sorption parameter for PCB-141 to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2.

5.45.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 9.30$; $K_F = 2.00\times10^9$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.95
- $R^2 = 0.99$

5.45.2 Sand

Sorption for PCB-141 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.45.3 Sediment

5.45.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-141 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.45.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- K_D = 596986.12 L/kg

5.46 PCB-153

5.46.1 Activated Carbon

The utilized sorption parameter for PCB-153 to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2. This value is slightly higher than the value presented in Chattopadhyay (2011).

5.46.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F)$ = 8.40 ; $K_F = 2.51 \times 10^8$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.72
- R^2 = 0.98

5.46.2 Sand

Sorption for PCB-153 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.46.3 Sediment

5.46.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-153 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. The results for PCB-153 was reported with coeluters (PCB-153/168). A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.46.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- K_D = 509501.86 L/kg

5.47 PCB-174

5.47.1 Activated Carbon

The utilized sorption parameter for PCB-174 to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2.

5.47.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 8.70$; $K_F = 2.51 \times 10^8$ (µg/kg)/((µg/L)^(1/n))
- $1/n = 0.71$
- $R^2 = 0.98$

5.47.2 Sand

Sorption for PCB-174 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.47.3 Sediment

5.47.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-174 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.47.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- $K_D = 790044.96$ L/kg

5.48 PCB-177

5.48.1 Activated Carbon

The utilized sorption parameter for PCB-177 to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2.

5.48.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 9.30$; $K_F = 2.00 \times 10^9$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.70
- $R^2 = 0.98$

5.48.2 Sand

Sorption for PCB-177 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.48.3 Sediment

5.48.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-177 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.48.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- $K_D = 843077.63$ L/kg

5.49 PCB-180

5.49.1 Activated Carbon

The utilized sorption parameter for PCB-180 to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2.

5.49.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 9.10$; $K_F = 1.26 \times 10^9$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.82
- $R^2 = 0.99$

5.49.2 Sand

Sorption for PCB-180 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.49.3 Sediment

5.49.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-180 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. The results for PCB-180 was reported with coeluters (PCB-180/193). A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.49.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- K_D = 668697.14 L/kg

5.50 PCB-183

5.50.1 Activated Carbon

The utilized sorption parameter for PCB-183 to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2.

5.50.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 8.30$; $K_F = 2.00\times10^8$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.69
- $R^2 = 0.98$

5.50.2 Sand

Sorption for PCB-183 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.50.3 Sediment

5.50.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-183 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. The results for PCB-183 was reported with coeluters (PCB-183/185). A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.50.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- K_D = 729680.97 L/kg

5.51 PCB-199

5.51.1 Activated Carbon

The utilized sorption parameter for PCB-199 to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2.

5.51.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F)$ = 8.00 ; $K_F = 1.00\times10^8$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.70
- R^2 = 0.98

5.51.2 Sand

Sorption for PCB-199 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.51.3 Sediment

5.51.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-199 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. The results for PCB-199 was reported with coeluters (PCB-198/199). A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.51.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- K_D = 7281538.79 L/kg

5.52 PCB-206

5.52.1 Activated Carbon

The utilized sorption parameter for PCB-206 to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2.

5.52.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 8.00$; $K_F = 1.00\times10^8$ (µg/kg)/((µg/L)^(1/n))
- $1/n = 0.60$
- $R^2 = 0.96$

5.52.2 Sand

Sorption for PCB-206 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.52.3 Sediment

5.52.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-206 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.52.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- $K_D = 2812708.78$ L/kg

5.53 PCB-209

5.53.1 Activated Carbon

Literature could not be found identifying the sorption of PCB-209 to activated carbon. As a conservative assumption, the utilized K_F sorption parameter for PCB-209 to GAC was assumed to be equal to the minimum K_F from the reported PCBs (PCB-136) in Gomez-Eyles et al. (2013). The Freundlich shape parameter, n, was assumed to equal 1, resulting in a linear relationship between aqueous and adsorbed concentrations. The Freundlich sorption isotherms are presented in Table S2.

5.53.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- $Log(K_F) = 6.90$; $K_F = 7.94 \times 10^6$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 1.00
- $R^2 = 0.94$

5.53.2 Sand

Sorption for PCB-209 to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Hawker & Connell (1988).

5.53.3 Sediment

5.53.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for PCB-209 to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.53.3.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- $K_D = 9321883.44$ L/kg

5.54 PENTACHLOROPHENOL

5.54.1 Activated Carbon

A literature review was conducted, and two sources were identified that are applicable to the sorption of pentachlorophenol to GAC: Lin (2014) and Dobbs & Cohen (1980). The sorption isotherms from Lin (2014) are presented in Table 2-2 of Pre-Final CDTM (Volume I, Appendix E). The sorption isotherm corresponding to pH 7.0 was selected from Dobbs & Cohen (1980) as it is closest to the expected conditions in SIB.

5.54.1.1 Modeled Sorption Isotherm

Lin (2014) reports a non-linear isotherm:

- $K_F = 436$ (mg/g)/((mg/L)^(1/n)) = 4.16×10^7 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.34

Dobbs & Cohen (1980) reports a non-linear isotherm:

- K_F = 0.33 (mg/g)/((mg/L)^(1/n)) = 8.24×10^6 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.42

An average of the two sources was used in CapSIM modeling:

- K_F = 2.49×10^7 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.38

5.54.2 Sand and Sediment

5.54.2.1 Literature Review

Sorption for pentachlorophenol to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. A literature review was conducted, and six sources were identified to be applicable to the sorption of pentachlorophenol to sands and sediments: Appendix D from Bureau of Habitat (2014), Table 1 of NJDEP(2014), the value for pH 6.8 from Table 42 of Superfund Soil Screening Guidance (EPA, 2023), Table 4 from Center for Environmental & Human Toxicology, University of Florida (2005), Table B-2 of New Mexico Environment Department (2021), and Table 7 of Division of Spill Prevention and Response Contaminated Sites Program (2018). To encapsulate the range of found literature values, the average log(K_{OC}) was utilized within CapSIM.

5.54.2.2 Modeled Sorption Isotherm

Bureau of Habitat (2014) Appendix D reports a linear (K_{OC}) isotherm:

- K_{OC} = 107954 L/kg = 5.03 log(L/kg)

NJDEP (2014) Table 1 reports a linear (K_{OC}) isotherm:

- K_{OC} = 5100 L/kg = 3.71 log(L/kg)

EPA (2023) Table 42 reports a linear (K_{OC}) isotherm:

- K_{OC} = 592 L/kg = 2.77 log(L/kg)

Center for Environmental & Human Toxicology, University of Florida (2005) Table 4 reports a linear (K_{OC}) isotherm:

- K_{OC} = 592 L/kg = 2.77 log(L/kg)

New Mexico Environment Department (2021) Table B-2 reports a linear (K_{OC}) isotherm:

- K_{OC} = 4960 L/kg = 3.695 log(L/kg)

Division of Spill Prevention and Response Contaminated Sites Program (2018) Table 7 reports a linear (K_{OC}) isotherm:

- K_{OC} = 592 L/kg = 2.77 log(L/kg)

The average log(K_{OC}) value from the five sources was used in CapSIM modeling:

- K_{OC} = 3.45 log(L/kg)

5.55 PHENANTHRENE

5.55.1 Activated Carbon

The utilized sorption parameter for phenanthrene to GAC was sourced from Gomez-Eyles et al. (2013). The Freundlich sorption isotherms are presented in Table S2. This value is higher than the reported isotherm in Lin (2014) and utilized in GeoEngineers (2022).

5.55.1.1 Modeled Sorption Isotherm

Gomez-Eyles et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- Log(K_F) = 8.71 ; K_F = 5.13×10^8 (µg/kg)/((µg/L)^(1/n))
- 1/n = 1.11
- R^2 = 0.95

5.55.2 Sand

Sorption for phenanthrene to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. A literature review was conducted, and the source identified to be applicable to the sorption of phenanthrene to sand and sediment was New Mexico Environment Department (2021). This K_{OC} value is in agreement with Alaska Department of Environmental Conservation, Division of Spill Prevention and Response Contaminated Sites Program (2018).

5.55.3 Sediment

5.55.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for phenanthrene to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project areas Cathedral Park and Fund-Lead 3. The calculated K_D values from Cathedral Park and Fund-Lead 3 presented in Table E-2 of the SPDI Evaluation were averaged. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.55.3.2 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm:

- K_D = 3.96 log(L/kg) = 9120.11 L/kg L/kg
- R^2 = 0.90

- n = 4

The Fund-Lead 3 linear (K_D) isotherm:

- K_D = 2.33 log(L/kg) = 213.80 L/kg
- n = 1

The average linear (K_D) isotherm used in CapSIM modeling:

- K_D = 4666.95 L/kg

5.56 PYRENE

5.56.1 Activated Carbon

The utilized sorption parameter for pyrene to GAC was sourced from Walters & Luthy (1984). The sorption isotherms are presented in Table III of this study. The Langmuir isotherm was determined by the researchers to be the most useful of the evaluated equations for representing the data. However, the Langmuir equation was not capable of describing the adsorption over the entire concentration range. The experimental data was reasonably fit by the Freundlich isotherm and was therefore selected. This value was additionally utilized by GeoEngineers (2022).

5.56.1.1 Modeled Sorption Isotherm

Walters & Luthy (1984) reports a non-linear isotherm, used in the CapSIM modeling:

- K_F = 389 (mg/g)/((mg/L)^(1/n)) = 2.70×10^7 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.386
- R^2 = 0.78

5.56.2 Sand

Sorption for pyrene to granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the granular material. The default K_{OC} value in CapSIM was utilized, which was sourced from Texas Commission on Environmental Quality's published Toxicity Values and Chemical – Physical Properties (TCEQ, 2019).

5.56.3 Sediment

5.56.3.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for pyrene to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent Cathedral Park and Fund-Lead 3. The calculated K_D values from Cathedral Park and Fund-Lead 3 presented in Table E-2 of the SPDI Evaluation were averaged. Individual sample sediment and transition zone water results are not available from the EPA-lead project areas, but the sample size is provided.

5.56.3.2 Modeled Sorption Isotherm

The Cathedral Park linear (K_D) isotherm:

- K_D = 4.77 log(L/kg) = 58884.37 L/kg L/kg
- R^2 = 0.65
- n = 16

The Fund-Lead 3 linear (K_D) isotherm:

- K_D = 3.34 log(L/kg) = 2187.76 L/kg
- n = 1

The average linear (K_D) isotherm used in CapSIM modeling:

- K_D = 4666.95 L/kg

5.57 TOTAL CPAHS

The ROD Table 17 Total cPAHs CULs are based on a benzo(a)pyrene equivalent. Total cPAHs were modeled using the same chemical and sorption properties as benzo(a)pyrene, the initial concentrations of Total cPAHs detected within the SIB project area, and resulting concentrations were compared to the CULs for Total cPAHs. See Section 5.16 for information on the sorption parameters used for Total cPAHs.

5.58 TOTAL DIOXINS/FURANS

The ROD Table 17 Total Dioxins/Furans CULs are based on a 2,3,7,8-TCDD equivalent. Total Dioxins/Furans were modeled using the same chemical and sorption properties as 2,3,7,8-TCDD, the initial concentrations of Total Dioxins/Furans detected within the SIB project area, and resulting concentrations were compared to the CULs for Total Dioxins/Furans. See Section 5.6 for information on the sorption parameters used for Total Dioxins/Furans.

5.59 TOTAL PAHS

Chemical inputs for Total PAHs, including sorption parameters, are the average values for the modeled individual PAHs, including cPAHs.

5.59.1 Activated Carbon

The utilized sorption parameter for Total PAHs to GAC was the average of the CapSIM default values for all PAHs included in the supporting materials. The PAHs where the sorption parameters were sourced from Dobbs & Cohen (1980) include benzo(a)pyrene, benzo(k)fluoranthene, and benzo(g,h,i)perylene. The PAHs where the sorption parameters were sourced from Walters & Luthy (1984) include acenaphthene, acenaphthylene, anthracene, benzo(a)anthracene, chrysene, fluoranthene, fluorene, naphthalene, phenanthrene, pyrene, and triphenylene.

5.59.1.1 Modeled Sorption Isotherm

An average of the 14 analytes was used in CapSIM modeling:

- $K_F = 1.45\times10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.47

5.60 TOTAL PCBS

Chemical inputs for Total PCBs, including sorption parameters for activated carbon and granular capping materials, are the average values for the modeled individual PCB congeners.

5.60.1 Activated Carbon

The utilized sorption parameter for Total PCBs to GAC was the average of all PCBs reported in Table S2 of Gomez-Eyles et al. (2013). Gomez-Eyles et al. (2013) reported 72 values representing 101 PCB congeners. Of the reported values, 25 report the sorption parameters for two or three coeluting congeners. Additionally, parameters are only reported for isotherms with more than three points and when the R^2 of the Freundlich fit is greater than 0.70.

5.60.1.1 Modeled Sorption Isotherm

An average of the 72 values was used in CapSIM modeling:

- $K_F = 2.40\times10^8$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.805

5.60.2 Sediment

5.60.2.1 Project Area-Adjacent Data Review

In the Draft 50% RD CDTM, sorption for Total PCBs to sediment used the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the sediment. Project Area-specific partitioning values (K_D) were measured at adjacent PHSS project area RM9W. RM9W presents the sediment and transition zone water results from eight sample locations and one duplicate per media. A K_D value for each sample location, excluding duplicates, was calculated and then averaged.

5.60.2.2 Modeled Sorption Isotherm

The average RM9W linear (K_D) isotherm, used in CapSIM modeling

- K_D = 447157.07 L/kg

5.61 TRIBUTYLTIN

5.61.1 Activated Carbon

Limited literature is available investigating the sorption of tributyltin to activated carbon. In the Draft 50% RD CDTM, the utilized sorption parameter for tributyltin to GAC was sourced from Ma et el. (2000). The research presented in Ma et al. (2000) focused on the distribution of tributyltin at the interfaces of the overlying water-sediment-pore water system under simulated estuarine conditions. The Freundlich sorption isotherms for tributyltin to sediment are presented in Figure 2 of this study, providing a conservative estimate of adsorption, and the value for experimental temperature of 25°C was selected. Ma et al. (2000) observed a strong influence of pH on both sorption of tributyltin on the sediment and partitioning into the porewater. Notable experimental assumptions and processes include:

- Sediment samples were acquired from sampling sites in Haihe estuary, Tianjin, China.
- Solution pH was 7.9, higher than the expected pH at the site (approximately 6.4).

Additional literature review was conducted, and Ayanda et al. (2013) was identified as applicable to the sorption of tributyltin to GAC. The research presented in Ayanda et al. (2013) focused on the adsorption potential of nFe3O4, activated carbon, and a composite in the removal of tributyltin from artificial seawater. The study utilized activated carbon (100–400 mesh) sourced from Sigma Aldrich. The adsorbent amount, contact time, pH, stirring speed, initial concentration, and temperature were varied to understand effect on adsorption capacity. The sorption isotherms are presented in Table 4 of this study. The Freundlich isotherm is used as the Langmuir constants are negative, indicating an inadequacy of the model to fit the data.

Ayanda et al. (2013) notes that increasing pH from 3 to 8 steadily increases the adsorbed percentage of tributyltin, followed by equilibrium at pH values above 8. It was also observed that the adsorption capacity increases with increased solution temperature as well as increased initial concentrations.

5.61.1.1 Modeled Sorption Isotherm

Ayanda et al. (2013) reports a non-linear isotherm, used in the CapSIM modeling:

- K_F = 6.6589 (mg/g)/((mg/L)^(1/n)) = 2.05×10^4 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.8375
- R^2 = 0.9977

5.61.2 Apatite

Literature describing tributyltin sorption to apatite could not be found.

5.61.3 Bauxite

Literature describing tributyltin sorption to bauxite could not be found.

5.61.4 Organoclay

A literature review was conducted and Du et al. (2000) was identified as applicable to the sorption of tributyltin to organoclay. The research presented in Du et al. (2000) focused on a new method to synthesize porous bentonite granules and assessing their removal capacity of tributyltin from wastewater. The sorption isotherms are presented in Figure 5 of Du et al. (2000) and the results for the porous organoclay granule were selected. Du et al. (2000) observed that all of the tested porous organoclay granules have a higher tributyltin adsorptive capacity than granules without surfactant (HDTMA) modification. Additionally, bentonite granules were determined to be a more practical amendment than bentonite powder, despite the higher sorptive capacity of the bentonite powder, due to the lack of swelling when wet and no dispersion into the water matrix. Notable experimental assumptions and processes include:

- Bentonite (Active Gel 150) was supplied from Sibelco Australia. Active Gel 150 is a sodium activated bentonite, mined and processed in Sandgate, New South Wales.
- Temperature was 23°C, higher than the expected temperature at the site (averaging between 4°C and 22°C)

5.61.4.1 Sorption Isotherm

Du et al. (2000) reports a non-linear isotherm, used in the CapSIM modeling:

- K_F = 2.8864 (mg/g)/((mg/L)^(1/n)) = 0.02161 (µg/kg)/((µg/L)^(1/n))
- 1/n = 2.7086

5.61.5 Sand and Sediment

5.61.5.1 Literature Review

Sorption for tributyltin to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. A literature review was conducted, and four sources were identified to be applicable to the sorption of tributyltin to sands and sediments: Table 3-2 of MFA (2009), Table 4 of Center for Environmental & Human Toxicology, University of Florida (2005), the average of the measured values in Table 2 of Unger et al. (1988), and Roy F. Weston, Inc. (1996). To encapsulate the range of found literature values, the average log(K_{OC}) was utilized within CapSIM.

5.61.5.2 Modeled Sorption Isotherm

MFA (2009) Table 3-2 reports a linear (K_{OC}) isotherm:

- K_{OC} = 5.17 log(L/kg)

Center for Environmental & Human Toxicology, University of Florida (2005) Table 4 reports a linear (K_{OC}) isotherm:

- K_{OC} = 9.08E+04 L/kg = 4.96 log(L/kg)

The average from Unger et al. (1988) Table 2 reports a linear (K_{OC}) isotherm:

- K_{OC} = 109250 L/kg = 5.04 log(L/kg)

Roy F. Weston, Inc. (1996) Section 3.6.1 reports a linear (K_{OC}) isotherm:

- K_{OC} = 25100 L/kg = 4.40 log(L/kg)

An average of the four sources was used in CapSIM modeling:

- K_{OC} = 4.89 log(L/kg)

5.62 VANADIUM

5.62.1 Activated Carbon

A literature review was conducted, and two sources were identified that are applicable to the sorption of vanadium to GAC: Chaudhari (2009) and Dessouki et al. (2000). The research presented in Chaudhari (2009) focused on improving the adsorption efficiency of GAC in removing vanadium from drinking water. The sorption isotherms for un-modified GAC are presented in Table 1 of this study as a control, and the Freundlich isotherm was selected for comparison with the other applicable source. Chaudhari (2009) observed a higher percentage removal at pH 2 and then a decreasing removal efficiency with increasing pH. Notable experimental assumptions and processes include:

- The commercially available GAC was supplied by an unknown manufacturer. The carbon was sieved through a mesh size (-12 × 18) (m/s Jayant Test sieves, Mumbai).
- Temperature was 25°C, higher than the expected temperature at the site (averaging between 4°C and 22°C).

The research presented in Dessouki et al. (2000) focused on the sorption of four heavy metals (uranium, molybdenum, zirconium, vanadium) to GAC and ion exchangers for the purposes of wastewater treatment. Heavy metal removal was studied under various pH values and initial concentrations ranging from 10 to 100 mg/L. The Freundlich sorption isotherms for GAC are presented in Table 1 of this study, and the sorption isotherm corresponding to pH 7.0 was selected as it is closest to the expected conditions in SIB. Dessouki et al. (2000) observed that GAC exhibited a higher adsorption capacity than the tested ion exchange resins and variation was noted depending on the chemical valency of the heavy metals. Notable experimental assumptions and processes include:

- Analyzed vanadium chloride (VCl_4) as V^{4+}
- Solution pH was 7.0, higher than the expected pH at the site (approximately 6.4).
- Temperature was 25°C, higher than the expected temperature at the site (averaging between 4°C and 22°C).

5.62.1.1 Modeled Sorption Isotherm

Chaudhari (2009) reports a non-linear isotherm:

- K_F = 1.228 (mg/g)/((mg/L)^(1/n)) = 1.55×10^5 (µg/kg)/((µg/L)^(1/n))

- 1/n = 0.2993
- R^2 = 0.9477

Dessouki et al. (2000) reports a non-linear isotherm:

- K_F = 5.60 (mg/g)/((mg/L)^(1/n)) = 3.15×10^4 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.75

An average of the two sources was used in CapSIM modeling:

- K_F = 9.34×10^4 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.525

5.62.2 Sand and Sediment

Sorption for vanadium to sediment and granular materials, such as capping Sand, uses the linear partition coefficient, K_D. A literature review was conducted, and two sources were identified that are applicable to the sorption of vanadium to Sand and Sediment: CLARC (2025) and NJDEP (2014).

5.62.2.1 Modeled Sorption Isotherm

The CLARC (2025) data table reports a linear (K_D) isotherm:

- K_D = 1000 L/kg

The NJDEP (2014) guidance document reports a linear (K_D) isotherm:

- K_D = 1000 L/kg

An average of the two sources was used in CapSIM modeling:

- K_D = 1000 L/kg

5.63 XYLENES

5.63.1 Activated Carbon

The utilized sorption parameter for xylenes to GAC was the average of the CapSIM default values for m-, o-, and p-xylenes. CapSIM documentation references three sources for isotherm parameters for pesticides and other compounds: Dobbs & Cohen (1980), Speth & Miltner (1990), and Speth et al. (1988). Speth et al. (1988) could not be verified. The CapSIM default parameters for o- and p-xylenes appear to have been sourced from Speth & Miltner (1990). The CapSIM default parameter source for m-xylene could not be verified from Dobbs & Cohen (1980) or Speth & Miltner (1990). The values for m-, o- and p-xylenes are slightly higher than the reported isotherms in Lin (2014).

5.63.1.1 Modeled Sorption Isotherm

The CapSIM default for m-xylene is a non-linear isotherm:

- $K_F = 3.56\times10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.25

The CapSIM default for o-xylene is a non-linear isotherm:

- $K_F = 9.76\times10^6$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.474

The CapSIM default for p-xylene is a non-linear isotherm:

- $K_F = 1.26\times10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.418

An average of the three analytes was used in CapSIM modeling:

- $K_F = 1.93\times10^7$ (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.381

5.63.2 Sand and Sediment

Sorption for xylenes to sediment and granular materials, such as capping Sand, uses the organic carbon normalized partition coefficient, K_{OC}, and the fraction organic carbon f_{OC} in the material. A literature review was conducted, and the source identified to be applicable to the sorption of xylenes to sand and sediment was Appendix D from Bureau of Habitat (2014). The log of presented K_{OC} values for 1,2-Xylene [3.07 log(L/kg)], 1,3-Xylene [3.15 log(L/kg)], and 1,4-Xylene [3.10 log(L/kg)] were calculated and the average of these values was used in CapSIM modeling.

5.64 ZINC

5.64.1 Activated Carbon

The utilized sorption parameter for zinc to GAC was sourced from Erto et al. (2015). The sorption isotherms are presented in Table 2 of this report, and the Freundlich isotherm was selected as the coefficient determination (R^2) was the highest and standard error was the lowest for both modeled contaminants.

5.64.1.1 Modeled Sorption Isotherm

Erto et al. (2015) reports a non-linear isotherm, used in the CapSIM modeling:

- $K_F = 0.101$ (mmol/g)/((mmol/L)^(1/n)) = 1.40×10^4 (µg/kg)/((µg/L)^(1/n))
- 1/n = 0.555
- $R^2 = 0.992$

5.64.2 Sand

Sorption for zinc to granular materials, such as capping Sand, uses the linear partition coefficient, K_D. A literature review was conducted, and two sources were identified that are applicable to the sorption of zinc to Sand: CLARC (2025) and NJDEP (2014).

5.64.2.1 Modeled Sorption Isotherm

The CLARC (2025) data table reports a linear (K_D) isotherm:

- K_D = 62 L/kg

The NJDEP (2014) guidance document reports a linear (K_D) isotherm:

- K_D = 23 L/kg

An average of the two sources was used in CapSIM modeling:

- K_D = 42.5 L/kg

5.64.3 Sediment

Sorption for zinc to sediment uses the linear partition coefficient, K_D. A literature review was conducted, and Allison & Allison (2005) was identified as applicable to the sorption of zinc to sediment.

5.64.3.1 Modeled Sorption Isotherm

The average of the median linear sorption parameters presented in Tables 1 and 4 of Allison & Allison (2005) reports a linear (K_D) isotherm, used in CapSIM modeling:

- K_D = 34,054 L/kg

CONTENTS

Cap Alternative 1: 30 centimeters [cm] of unamended sand with 30 cm erosion protection layer/unamended habitat mix (EPL/UHM) 3
Porewater Concentration – Depth 3
Total Solids Concentration – Depth 36
Cap Alternative 2: 15 cm of 5.0% GAC amended sand with 30 cm EPL/UHM 68
Porewater Concentration - Depth 68
Total Solids Concentration – Depth 101
Cap Alternative 3: 30 cm of 5.0% GAC amended sand with 30 cm EPL/UHM 133
Porewater Concentration - Depth 133
Total Solids Concentration – Depth 166
Cap Alternative 4: 30 cm of 10.0% GAC amended sand with 30 cm EPL/UHM 198
Porewater Concentration - Depth 198
Total Solids Concentration – Depth 231
Cap Alternative 5: 30 cm of 20.0% GAC amended sand with 30 cm EPL/UHM 263
Porewater Concentration - Depth 263
Total Solids Concentration – Depth 296
Cap Alternative 6: 76 cm of 20.0% GAC amended sand with 30 cm EPL/UHM 328
Porewater Concentration - Depth 328
Total Solids Concentration – Depth 361
Cap Alternative 7: 2 cm Tektoseal-AC with 30 cm of 2.5-inch bedding stone and 60 cm of 10-inch armor stone 393
Porewater Concentration - Depth 393
Total Solids Concentration – Depth 426
Cap Alternative 8: 2 cm Tektoseal-HM with 30 cm of 2.5-inch bedding stone and 60 cm of 10-inch armor stone 458
Porewater Concentration - Depth 458
Total Solids Concentration – Depth 491
Cap Alternative 9: 2 cm hybrid of Tektoseal-AC and Tektoseal-HM with 30 cm of 2.5-inch bedding stone and 60 cm of 10-inch armor stone 524
Porewater Concentration - Depth 524
Total Solids Concentration – Depth 557
Cap Alternative 10: 2 cm Tektoseal-AC and 2 cm Tektoseal-HM with 30 cm of 2.5-inch bedding stone and 60 cm of 10-inch armor stone 589
Porewater Concentration - Depth 589

Total Solids Concentration – Depth 622
Cap Alternative 11: 4 cm Tektoseal-AC with 30 cm of 2.5-inch bedding stone and 60 cm of 10-inch armor stone 654
Porewater Concentration - Depth 654
Total Solids Concentration – Depth 687
Example 0 µg/L porewater concentration at CPP over time: arsenic in Cap Alternative 3 719

The Cap Performance Point (CPP) is at the top surface of the chemical isolation layer and under Erosion Protection Layer (EPL)/Unamended Habitat Mix (UHM).

Cap Alternative 1: 30 centimeters [cm] of unamended sand with 30 cm erosion protection layer/unamended habitat mix (EPL/UHM)

WASTE DESIGNATION MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
SWAN ISLAND BASIN PROJECT AREA, CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

1.0 INTRODUCTION

This Waste Designation Memorandum describes methods for the designation of soil and sediment wastes and presents data needed by the Remedial Action (RA) Performing Parties and their consultants to arrange for the off-site disposal of the wastes generated during RA at the Swan Island Basin (SIB) Project Area within the Portland Harbor Superfund Site (PHSS) in Portland, Multnomah County, Oregon. The HydroGeoLogic, Inc. (HGL) team developed this memorandum on behalf of the SIB Remedial Design (RD) Group based on the requirements of the PHSS Record of Decision (ROD) (EPA, 2017) and the Administrative Settlement Agreement and Order on Consent (ASAOC) (EPA, 2021). This memorandum was developed in accordance with the Remedial Design Work Plan (HGL, 2025) and includes references to the U.S Environmental Protection Agency (EPA)-approved Pre-Design Investigation (PDI) dataset (HGL, 2024).

This memorandum provides a preliminary waste designation screening for soil and sediment within the SIB Project Area to be removed during excavation and dredging performed during RA activities. Water including dredge return water is addressed in the Water Quality Monitoring Plan (Attachment C of the Construction Quality Assurance/Quality Control Plan [Volume II, Appendix N). As part of the preliminary waste screening, existing soil and sediment results collected during the PDI (HGL, 2024b) are screened against Resource Conservation and Recovery Act (RCRA) Landfill Disposal Requirements, Toxic Substances Control Act (TSCA), Oregon Waste Regulations (Oregon Administrative Rule [OAR], Chapter 340, Divisions 93-103, 2025), and Washington Dangerous Waste Regulations (Washington Administrative Code [WAC] 173-303, 2020) to indicate whether material can be managed as nonhazardous waste, or if hazardous (federal or Oregon) or dangerous waste (Washington) regulations may apply. Although the SIB Project Area is located in Oregon, Washington state waste regulations are also included as part of the screening in the event the selected disposal facility is located in Washington. The preliminary waste designation screening results in this memorandum are available to the RA Performing Parties and their consultants to help inform their plans for excavated and dredged material management as part of remedy implementation. If the preliminary waste designation screening results indicate specific excavation areas (EAs) or dredge areas (DAs) may designate as hazardous, additional sampling and analyses may be required, as discussed in Section 3.0. The preliminary waste screening designation should be re-evaluated by the RA Contractor prior to RA in coordination with the selected waste disposal facility, EPA, and relevant state agencies to determine the requirements for final waste designation. It is expected that waste characterization sampling will be performed by the RA Performing Parties on samples in EAs or DAs where material has the potential to be classified as hazardous waste based on the toxicity characteristic to obtain final waste designation prior to RA construction to ensure an efficient and cost-effective remedy implementation.

Corporate Headquarters
11107 Sunset Hills Road, Suite 400
Reston, Virginia 20190
703-478-5186

The RA Performing Parties and their consultants and contractors will be responsible for selecting the specific off-site disposal facility, addressing final waste designation (e.g., additional sampling and analyses) with the disposal facility, EPA, and state agencies, and determining acceptance criteria required for receipt of soil and sediment derived from EAs and DAs during remedy construction. It is expected that final waste designation will be documented in an EPA-approved RA Work Plan prior to the start of remedy implementation.

2.0 EXCAVATION AND DREDGE AREAS

The Pre-Final 90% RD prescribes areas within the SIB Project Area to be excavated or dredged as part of remedy implementation. Those areas and estimated excavation and dredge depths are shown on Figure 2-1. Based on the spatial distribution and lateral extent of excavation and dredging, EAs and DAs have been established to segregate areas for preliminary waste designation based on the most recent soil and sediment data collected as part of the PDI (HGL, 2024b).

The Pre-Final 90% RD approach to riverbanks is a combination of excavation and backfilling to achieve the required slopes for stability. The spatial distribution of excavation versus filling is granular and highly variable across the SIB Project Area. Therefore, riverbank soil samples for the entire SIB Project Area are included in the waste designation screening. Riverbank soil samples are separated spatially into four EAs as shown on Figure 2-1[1]. Similarly, six DAs have been established as shown on Figure 2-1. Excavation and dredge volumes within the EAs and DAs are provided in Table 2-1.Table 2-1 and Figure 2-1 also present the dredge, cap, or riverbank certification units (DCU, CCU, RCU, respectively) associated with each area. Excavation and dredge volumes were calculated based on cross-section details provided in the Drawings (Volume III, Appendix V). Volumes presented in Table 2-1 align with the Probabilistic Cost Model input volumes presented in the Cost Analysis Technical Memorandum (Volume I, Appendix K).

Table 2-1 Estimated Excavation and Dredge Volumes

Dredge Area	Corresponding Certification Unit	Excavation/Dredge Volume (cubic yards)
DA-1	DCUs 19-23	98,700
DA-2	DCUs 13-18 CCUs 63-67 CCUs 87-94	145,400
DA-3	CCUs 68-78	39,000
DA-4	DCUs 7-12 CCUs 49-57 CCU 11	187,600
DA-5	DCUs 1-6 CCUs 26-48	108,000
DA-6	CCUs 18-22	6,700
EA-1	RCUs 28-30	17,430
EA-2	RCUs 16-24	12,850

[1] Riverbank soil beneath the Lagoon Wharf structure is not included in excavation areas. The remedial design for riverbank soil in this area is in progress but as of the 90% RD, does not include excavation and subsequent disposal. Additional details on the disposition of riverbank soil under Lagoon Wharf will be provided in a supplemental appendix to the Pre-Final 90% RD and quantities presented in Table 2-1 will be updated appropriately in the Final 100% RD.

Dredge Area	Corresponding Certification Unit	Excavation/Dredge Volume (cubic yards)
EA-3	RCUs 8-15	61,650
EA-4	RCUs 1-7	29,770
	Total	707,100

Notes:
CCU = Cap Certification Unit
DA = dredge area
DCU = Dredge Certification Unit
EA = excavation area
RCU = Riverbank Certification Unit

3.0 PRELIMINARY SOIL AND SEDIMENT DESIGNATION SCREENING

3.1 EVALUATION OF EXISTING SOIL AND SEDIMENT DATA

Soil and sediment data collected during the PDI (HGL, 2024b) were queried against the EAs and DAs to establish a refined dataset for preliminary waste designation screening evaluation. PDI samples collected outside the EAs and DAs were not included in the preliminary waste designation screening evaluation. The PDI analytical sampling suite was designed to address data gaps identified prior to RD and included contaminants of concern (COCs) listed in the Record of Decision (ROD) Tables 17 (EPA, 2020) and Table 21 (EPA, 2022). Toxicity Characteristic Leaching Procedure (TCLP) analysis was not performed on PDI samples since waste characterization sampling for RA disposal was not an objective of PDI sampling. Although it is unlikely that any material removed during RA will classify as hazardous waste given concentrations for excavated soil and dredge sediment collected to date have not designated as hazardous waste, screening is necessary prior to RA construction activities to meet disposal requirements. COCs listed in ROD Tables 17 and 21 that are regulated under federal and state waste designation criteria (volatile organic compounds [VOCs], semivolatile organic compounds [SVOCs], pesticide/herbicides, metals, polycyclic aromatic hydrocarbons [PAHs], and polychlorinated biphenyls [PCBs]) and within the refined PDI dataset were screened against applicable federal and state characterization criteria to identify EAs and DAs that designate as non-hazardous or warrant additional actions prior to final waste designation. The federal and state waste screening processes are detailed in Sections 3.2 and 3.3, respectively.

3.2 FEDERAL SCREENING

The PDI data were screened against federal waste regulatory requirements listed in RCRA (Listed Wastes, Characteristic Wastes) and TSCA. Results of the preliminary screening are provided in Section 3.2.1. and 3.2.2.

3.2.1 RCRA Hazardous Waste Screening Evaluation

RCRA listed hazardous wastes are identified as wastes derived from common manufacturing and industrial processes (F-list) and wastes derived from specific sectors of industry and manufacturing (K-list). Soil and sediment from excavation and dredging during RA are classified as contaminated environmental media and are not directly derived from manufacturing or industrial waste streams. Therefore, soil and sediment generated during RA do not meet the requirements for listed hazardous waste under RCRA.

Characteristic hazardous wastes are defined under RCRA as wastes that possess characteristics that exceed the established thresholds for ignitability, corrosivity, reactivity, and toxicity. PDI samples were not analyzed for ignitability, corrosivity, and reactivity; however, these characteristics were analyzed in investigative derived waste (IDW) generated during the PDI prior to transport and disposal. IDW samples consisted of excess soil and sediment collected during PDI sampling; therefore, the hazardous waste characteristics of the IDW are assumed to be representative of soil and sediment that will be removed during RA. IDW results indicated that all material was below the respective hazardous waste thresholds for ignitability, corrosivity, and reactivity, and, as a result, these characteristics will not contribute to soil and sediment waste designation within the SIB Project Area.

To determine whether soil and sediment exceed the toxicity characteristic, PDI data were compared to screening levels based on Toxicity Characteristic Regulatory Levels in accordance with Code of Federal Regulations (CFR), Title 40, Part 261.24 (40 CFR 261.24) (EPA, 2025). TCLP analysis (EPA, 1992) for the federal toxicity characteristic, as defined in 40 CFR 261.24, is performed by the analytical laboratory that prepares a simulated landfill leachate by extracting regulated constituents from the waste sample using a weak acid solution. The mass of the extraction fluid is 20 times the mass of the waste sample. Given this dilution, wastes with total constituent concentrations (in milligrams per kilogram [mg/kg]) that are less than 20 times the Toxicity Characteristic Regulatory Levels cannot have TCLP results that exceed the regulatory levels. The dilution factor is used to derive screening levels to identify wastes that have the potential to be hazardous waste based on the toxicity characteristic (referred to as the "20 times screening tool"). Attachment A presents constituents, EAs, DAs, sample locations and depths that exceeded the 20 times screening tool TCLP screening levels for metals. No VOC, SVOC, or pesticide/herbicide constituent concentrations exceeded the TCLP screening levels, and, as a result, are not included in Attachment A.

A total of 268 PDI sediment samples located within DAs 1-6 and 1,340 soil samples located within EAs 1-5 were screened against TCLP screening levels for metals, SVOCs, pesticide/herbicides, and VOCs. Table 3-1 presents the total number of samples screened, number of 20 times screening tool exceedances, and constituent or constituents that exceeded for each of the EA or DA. Figure 3-1 shows the locations for all samples included in the screening and includes samples with TCLP Screening Level exceedances.

Table 3-1 Summary of Toxicity Characteristic Screening Results

DA/EA	Samples Screened	Cubic Yards/Sample	Samples Exceeding 20x Screening Tool	Percent of Samples Exceeding 20x Screening Tool	Constituent(s) Exceeding 20x Screening Tool
DA-1	6	18,575	0	0	--
DA-2	89	1,529	41	46	Mercury, Lead
DA-3	31	1,688	11	35	Mercury, Lead
DA-4	105	1,089	0	0	--
DA-5	29	1,657	1	3	Lead
DA-6	8	1,097	0	0	--
EA-1	114	128	2	2	Lead
EA-2	404	136	3	1	Lead
EA-3	446	146	0	0	--
EA-4	137	178	0	0	--

EPA sample density specifications for pre-remedy construction waste disposal designation that was provided in the Gasco[2] Sediments Site Statement of Work (EPA, 2009) required 1 composite sample for TCLP analysis per 10,000 cubic yards. For all EAs and DAs other than DA-1, the sample density based on estimated excavation and dredging volumes are well below 10,000 cubic yards per sample indicating sufficient data to inform preliminary waste characterization.

All samples screened within DA-1, DA-4, DA-6, and EA-4 were below TCLP 20 times screening tool levels. DA-5, EA-1, and EA-2 had 3 percent or less of samples that exceeded TCLP 20 times screening tool levels, while DA-2 and DA-3 had sample exceedances of 46 and 35 percent, respectively. Based on the absence or minimal percentage of TCLP 20 times screening tool exceedances for DA-4, DA-5, DA-6, EA-1, EA-2, EA-3, and EA-4, no additional waste designation actions are warranted based on RCRA hazardous waste criteria prior to final waste designation. DA-1 has limited PDI data and large estimated dredge volume, resulting in a significantly lower sample density for preliminary waste screening. As a result, additional waste characterization sampling within DA-1 may be needed prior to RA construction to obtain final waste designation. DA-2 and DA-3 had significantly higher percentages for TCLP 20 times screening tool exceedances which may need further waste characterization sampling prior to RA construction.

In order to characterize sediment dredged from DA-1, DA-2, and DA-3 for waste disposal, additional sampling is needed. Based on the estimated dredge volumes and EPA sample density specifications for the Gasco Sediments Statement of Work (EPA, 2009), pre-RA waste characterization sampling will include collection of 11 composite soil samples from DA-1, 14 from DA-2, and 5 from DA-3 to achieve a density of 1 composite sample per 10,000 cubic yards of dredged material. For RA Contractor assumptions, these DAs and sample quantities should be assumed for pre-construction waste designation sampling prior to final waste designation.

3.2.2 TSCA Hazardous Waste Screening Evaluation

PCBs are the only compound regulated under TSCA as it pertains to hazardous waste designation. The hazardous waste threshold for PCBs in soil and sediment under TSCA is 50 mg/kg. Out of the 847 samples analyzed for PCBs within the EA/DAs, the highest concentration of PCBs collected as part of the PDI in soil or sediment was 16.4 mg/kg. Therefore, no further waste designation actions for PCBs are warranted prior to final waste designation.

3.3 STATE SCREENING

3.3.1 Oregon State Hazardous Waste Screening Evaluation

The Oregon State solid and hazardous waste criteria are defined in OAR, Chapter 340, Divisions 93-103 and 109. OAR has adopted 40 CFR 261.24 and federal RCRA and TSCA regulations for waste designation prior to disposal of material in municipal solid waste landfills. Therefore, excavated soil and dredged sediment will be subject to the same preliminary waste screening analysis presented in Section 3.2 above.

[2] Gasco Sediments Project Area, Portland, Oregon

3.3.2 Washington State Dangerous Waste Screening Evaluation

If the RA Contractor chooses to dispose of soil and sediment at a Washington State landfill, WAC 173-303 and its regulatory levels will apply. TCLP screening levels listed in 40 CFR 261.24 are also included in WAC 173-303-090; therefore, additional waste characterization actions discussed in Section 3.2.1 are also applicable to Washington State designation.

According to WAC 173-303-070, if waste is not designated as dangerous waste based on TCLP testing performed in accordance with WAC 173-303-090, waste will need to undergo the Washington state-specific toxicity determination that requires comparison of bulk chemistry concentrations to certain published toxicity data (WAC 173-303-100). Therefore, since TCLP was not been performed on PDI soil and sediment samples, PDI concentrations of metals from discrete samples within each DA and EA were screened against toxicity criteria listed in Registry of Toxic Effects of Chemical Substances (RTECS) (BIOVIA, 2025) to adhere to the requirements of WAC 173-303-100. Maximum concentration percentages by area for metals were calculated for each DA and EA. These values were calculated by converting the maximum metal concentrations to an equivalent percentage of the bulk sediment or soil sample (i.e., 5 mg/kg is converted to 5 parts per million [ppm], then to 0.0005 percent). Equivalent concentrations were then calculated by dividing each maximum metal percentage by a toxic category value as defined by WAC 173-303-100, then summing these results for each area. These equivalent concentrations are compared to the Washington State dangerous waste threshold percentage of 0.001. Results of the Washington state-specific screening for metals in sediment and soil are presented in Tables 3-2 and 3-3, respectively.

WAC 173-303-100 also requires screening of total PAH concentrations for persistent waste determination. Soil and sediment with a total PAH concentration greater than 1.0 percent (10,000 mg/kg) is designated as persistent waste under WAC 173-303-100. The maximum total PAH concentration from PDI samples collected within the DAs and EAs was 0.009 percent (90.8 mg/kg). Therefore, no additional waste designation actions are required to determine Washington State persistent waste criteria prior to final waste designation.

Table 3-2 Summary of Washington State Dangerous Waste Screening Results for Sediment

Constituent	Toxic Category[1]	Maximum Concentration By Area Percentage (%)					
		DA-1	DA-2	DA-3	DA-4	DA-5	DA-6
Arsenic	A	0.000501	0.00666	0.00206	0.0017	0.000928	0.000755
Cadmium	D	0.000025	0.000195	0.000108	0.000071	0.000073	0.0000635
Chromium	D	No Data	No Data	No Data	No Data	No Data	No Data
Copper	D	0.0134	0.206	0.0767	0.0181	0.0154	0.0183
Lead	B	0.00217	0.195	0.0618	0.0095	0.0138	0.00915
Mercury	B	0.0000117	0.00186	0.00102	0.0000582	0.00005	0.00008645
Silver	D	No Data	No Data	No Data	No Data	No Data	No Data
Zinc	D	0.0197	0.138	0.0895	0.0359	0.043	0.0265
Equivalent Concentration[2]		0.000075	0.002669	0.000851	0.000271	0.000237	0.000172
Dangerous Waste Designation[3]		NDW[4]	WT02, special waste	NDW	NDW	NDW	NDW

Notes:
[1] Toxic categories determined from RTECS per WAC 173-303-100(5)(b)(1)

[2] Equivalent Concentration calculated using the formula provided in WAC 173-303-100(5)(b)(1) based on the toxic categories (X, A, B, C, and D)
[3] Dangerous Waste designation determined based on the Equivalent Concentration per WAC 173-303-100(5)(b)(1).
[4] NDW = not a toxic dangerous waste (equivalent concentration below 0.001%)
% = percent

Based on bulk sediment chemistry analysis of metals, DA-1, DA-3, DA-4, DA-5, and DA-6 designate as non-dangerous waste according to the Washington state-specific criteria. However, the absence of chromium and silver data should be noted and considered prior to additional waste characterization sampling as inclusion of chromium and silver, despite not being listed in ROD Table 17, may be a Washington State or landfill requirement. No additional waste designation actions are warranted for DA-1, DA-3, DA-4, DA-5, and DA-6 based on Washington State dangerous waste criteria prior to final waste designation; however, as discussed in Section 3.2.1, additional waste characterization sampling may be needed for DA-1, DA-2, and DA-3 based on RCRA criteria.

Sediment within DA-2 exceeded TCLP screening levels and could classify as WT02 dangerous waste based on bulk sediment chemistry screening. Therefore, based on the bulk sediment chemistry screening, additional discrete sample collection could be needed within DA-2 for final Washington state-only dangerous waste designation, if the selected disposal facility is located in Washington.

Table 3-3 Summary of Washington State Dangerous Waste Screening Results for Soil

Constituent	Toxic Category[1]	Maximum Concentration By Area Percentage (%)			
		EA-1	EA-2	EA-3	EA-4
Arsenic	A	0.00685	0.00162	0.00285	0.00119

Dangerous Waste Designation[3]		NDW	NDW	NDW	NDW

Notes:
[1] Toxic categories determined from RTECS per WAC 173-303-100(5)(b)(1)
[2] Equivalent Concentration calculated using the formula provided in WAC 173-303-100(5)(b)(1) based on the toxic categories (X, A, B, C, and D)
[3] Dangerous Waste designation determined based on the Equivalent Concentration per WAC 173-303-100(5)(b)(1).
[4] NDW = not a toxic dangerous waste (equivalent concentration below 0.001%)
% = percent

Based on bulk soil chemistry analysis of metals, EA soils designate as non-dangerous waste according to the Washington state-specific criteria. However, the absence of chromium and silver data should be noted and considered prior to additional waste characterization sampling as inclusion of chromium and silver, despite not being listed in ROD Table 17, may be a Washington State or landfill requirement.

3.4 PRELIMINARY WASTE DESIGNATION SCREENING RESULTS

Based on the preliminary waste screening, soil and sediment to be excavated and dredged within all EAs and DA-3, DA-4, DA-5, and DA-6 will not designate as hazardous under either federal or state regulations. As discussed in Section 3.2.1, additional composite waste characterization sampling within DA-1, DA-2, and DA-3 may be needed based on RCRA criteria prior to final waste characterization. Similarly, as discussed in Section 3.3.2, additional discrete sampling may be needed in DA-2 based on Washington State criteria if the selected disposal facility is in Washington. As a result, the RA Performing Parties will be required to collect additional composite samples for TCLP analyses for final waste designation prior to RA. If the disposal facility is located in Washington, additional discrete samples for Washington state bulk chemistry screening will also be required. If TCLP analyses results from additional sample collection in DA-1, DA-2, and DA-3 are below RCRA regulatory levels and the waste disposal facility is located in Oregon, no additional actions are required prior to final waste designation. If TCLP analyses results are below regulatory levels and the waste disposal facility is located in Washington, Washington state-specific waste designation screening listed in WAC 173-303-100 will need to be conducted prior to final waste designation.

Additional waste characterization sampling and analyses will be performed by the RA Performing Parties and their consulting experts in coordination with the selected disposal facility, EPA, and relevant state agencies prior to remedy implementation. We understand that the additional waste designation actions and final waste designations will be documented in the RA Work Plan to be submitted and approved by the EPA prior to RA.

4.0 DEBRIS AND CONSTRUCTION AND DEMOLITION WASTE DISPOSAL

In preliminary discussions with a potential Oregon State solid waste disposal facility (Wasco County, 2024), waste designation for debris and construction/demolition materials removed during RA is not anticipated to be needed. If construction and demolition materials are suspected to contain asbestos, sampling will be required in coordination with the selected disposal facility, EPA, and relevant state agencies prior to disposal. Metal debris and materials may be recycled to the extent practicable, as determined by the RA Performing Parties and their consulting experts. Log, piling, or other debris and construction material lengths will need to be less than 8 feet in length prior to disposal.

CLEAN WATER ACT ANALYSIS TECHNICAL MEMORANDUM

This page was intentionally left blank.

CLEAN WATER ACT ANALYSIS TECHNICAL MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
SWAN ISLAND BASIN PROJECT AREA, CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

1.0 INTRODUCTION AND PURPOSE

This Clean Water Act Analysis presents a Project Area-specific evaluation of Clean Water Act (CWA) Section 404(b)(1) and other applicable sections of the CWA as applied to the Remedial Design (RD) conducted for the Swan Island Basin (SIB) Project Area within the Portland Harbor Superfund Site (PHSS) in Portland, Multnomah County, Oregon. HydroGeoLogic, Inc. (HGL) performed the work on behalf of the SIB RD Group based on the requirements of the PHSS Record of Decision (ROD) (EPA, 2017) and the Administrative Settlement Agreement and Order on Consent (ASAOC) (EPA, 2021a). This CWA analysis uses references to the previously published SIB Project Area Pre-Design Investigation (PDI) Evaluation Report (ER), submitted in December 2024 (HGL, 2024a) and approved by the U.S. Environmental Protection Agency (EPA) in January 2025. References also are made to the Basis of Design Report (BODR) that was submitted to EPA in November 2024 (HGL, 2024b) and approved by EPA in December 2024. This CWA analysis has been revised to address EPA comments on the CWA analysis that was included in the Draft 50% RD.

As required by the ASAOC, the purpose of this CWA analysis is to provide sufficient information to demonstrate that the proposed Remedial Action (RA) at the SIB Project Area complies with the substantive requirements of Section 404(b)(1) and other applicable sections of the CWA. Most of the information necessary to do so was previously compiled and published in the CWA Section 404(b)(1) evaluation in Appendix L of the PHSS Feasibility Study (FS) (EPA, 2016). This CWA analysis supplements that previously published analysis regarding long-term and short-term impacts to Waters of the U.S. resulting from the RA at the SIB Project Area, minimization of adverse effects to Waters of the U.S., compliance with the ROD, and an analysis of the need for any mitigation. In response to EPA comments on the Draft 50% RD, the organization of this CWA analysis has been structured to align with the outline of Appendix L of the PHSS FS. Broadly, the findings of that prior CWA analysis reported in that prior analysis remain applicable to the RD for the SIB Project Area. This CWA analysis amends that prior study by providing greater detail regarding the primary elements of the RD, specific impacts related to the RD in the context of the SIB Project Area, and application of best management practices (BMPs), engineering controls, and other avoidance and minimization measures. This CWA analysis addresses CWA Sections 404 and 401, and Oregon Water Quality Standards. It is not a comprehensive analysis of all Applicable or Relevant and Appropriate Requirements (ARARs) identified in the ROD. The complete analysis of ARARs is included in Section 2.3.1 and Table 2-1 of the Design Criteria Report (DCR).

This CWA analysis provides the basis for the EPA to determine whether compensatory mitigation is needed to satisfy CWA requirements. The Remedial Design Guidelines and Considerations (RDGC), in Appendix B Topic 9 “Habitat Mitigation” (EPA, 2021b), presents EPA guidance on

Corporate Headquarters
11107 Sunset Hills Road, Suite 400
Reston, Virginia 20190
703-478-5186

determining, and if needed, satisfying the requirements for compensatory mitigation during RD at the PHSS. The RDGC (EPA, 2021b) guides remedial designs to be "self-mitigating" to the extent on-site measures to maintain aquatic habitats and ecological functions are feasible. The ROD and the RDGC both provide avenues for additional compensatory mitigation in the event that RD does not achieve a "self-mitigating" outcome.

The ROD identified CWA 404 and State of Oregon Water Quality Standards as ARARs. This analysis determines the applicability of those ARARs to the SIB Project Area RA and identifies the various ways those requirements are addressed within the Pre-Final 90% RD, including the Project Area Monitoring Plan (PAMP) (Volume II, Appendix P) and Water Quality Monitoring Plan (WQMP) (Volume II, Attachment C of Appendix N - Construction Quality Assurance/Quality Control Plan [CQA/QCP]).

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) provides that "no federal, state or local permit shall be required for the portion of any removal or remedial action conducted entirely on-site" (42 United States Code ["USC"] 9621 (e)). This provision of CERCLA does not remove the requirement to equivalently meet or waive the permitting regulations that are identified by EPA to be ARARs. Although CERCLA projects are exempt from securing such permits, the lead agency is responsible for consulting with regulatory stakeholders through the permit equivalency process, which enables regulatory agency and stakeholder review of proposals and applications to achieve a demonstrable level of compliance consistent with the spirit and intent of regulatory guidelines identified as ARARs. The regulatory equivalency analysis summarizes the project, applicable regulations, potential environmental impacts, BMPs, and project monitoring plans to facilitate regulatory engagement, dialog, and guidance. This CWA analysis addresses a substantial portion of the permit equivalency analysis.

EPA is the lead agency for the PHSS. CERCLA stipulates that a remedy that does not attain an ARAR can be selected if it assures the protection of human health and the environment and meets one of six waiver criteria described in CERCLA. At this time, EPA has not waived any of the ARARs identified in the ROD (EPA, 2017).

1.1. PROJECT BACKGROUND

The SIB Project Area is the active cleanup area within the PHSS that lies between approximately river mile (RM) 8.1 and RM 9.2 on the northeast side of the Willamette River. The SIB Project Area is approximately 1.1 miles in length and 117 acres in size and includes riverbanks from the top of the bank to the river. The SIB Project Area is adjacent to a federal navigation channel within the main channel of the Willamette River. The navigation channel has an authorized maintained depth of -45 feet (ft) Columbia River Datum (CRD), extending from the confluence of the Lower Willamette River with the Columbia River to RM 11.6. The U.S. Army Corps of Engineers (USACE) maintains the navigation channel, which does not extend into SIB.

The SIB Project Area is bounded by the uplands of Swan Island and Mocks Bottom to the southwest and northeast, respectively. Land uses within and adjacent to the SIB Project Area are light and heavy industrial and commercial. SIB is an active navigable industrial waterway, and the shoreline hosts many structures supporting light and heavy industrial activities. Except for slopes

along the riverbanks, the basin upland topography is generally flat, with elevations varying between 34 to 44 North American Vertical Datum of 1988 (NAVD88).

The Portland Harbor reach of the Willamette River, including the SIB Project Area, has been redirected, straightened, filled, and deepened by dredging. Most of the riverbank has been filled, stabilized, and engineered for industrial-type operations with riprap, bulkheads, and overwater piers and docks. (City of Portland, 2014).

1.2. PROJECT PURPOSE AND NEED

The purpose and need for the proposed remedy within the SIB Project Area has not changed from the project purpose and need described for the PHSS in Appendix L of the PHSS FS. The PHSS is located within Waters of the U.S. The basic purpose of the proposed remedy is to remove and remediate contaminated sediments within the SIB Project Area. The need for RA arises from unacceptable risks to human health and ecological receptors resulting from exposure to contaminants of concern (COCs) in sediments, groundwater, surface water, fish tissue, and riverbank soils within the SIB Project Area.

1.3. OBJECTIVES

Remedial Action Objectives (RAOs) were developed for the PHSS during the FS phase and published in the ROD. RAOs include media-specific goals for protecting human health and the environment. RAOs are published and detailed in Section 9 of the ROD (EPA, 2017).

1.4. WATER DEPENDENCY DETERMINATION

The Pre-Final 90% RD addresses contaminated sediment and riverbanks located within or adjacent to Waters of the U.S. Therefore, as stated in Appendix L of the FS, the proposed RA is a water-dependent activity (40 CFR Section 230.10).

2.0 DESCRIPTION OF THE PROPOSED REMEDY

2.1. PROJECT LOCATION

Section 1.1. identifies the project location with supporting details and context. The SIB Project Area is located in Portland, Oregon, Multnomah County within the PHSS located on the northeast side of the Willamette River between river mile (RM) 8.1 and RM 9.2.

2.2. PRIMARY ELEMENTS OF THE REMEDY

The Pre-Final 90% RD applies a combination of remedial technologies to achieve RAOs in compliance with the requirements of the ROD and the guidance provided by the RDGC. The proposed remedy predominantly applies dredging and capping to accomplish RAOs. The primary elements of the proposed remedy are listed below in a way that aligns with the applicable remedy components discussed in Appendix L of the PHSS FS:

- Containment
- Sediment/Soil Removal

- Upland (Off-site) Disposal
- Removal and Installation of Piling and Structures

Although discussed in Appendix L of the PHSS FS, the proposed remedy for SIB Project Area does not include monitored natural recovery, enhanced natural recovery, or in situ treatment. Therefore, those technologies are not discussed here.

2.2.1. Containment

The proposed remedy includes engineered caps designed to achieve chemical isolation of contaminated sediments and soils that remain in place at the SIB Project Area. The Pre-Final 90% RD includes multiple cap designs that vary between riverbank application and in-water application. Additional variations arise depending on the need for an erosion protection layer to protect cap performance and the spatial variability of contaminant concentrations within the riverbed.

Details regarding cap design, supporting engineering analysis, and locations for cap placement are found within the Pre-Final 90% RD documents at the following locations:

- DCR, Section 3.2 Cap Design
- DCR, Section 3.3 Riverbank Design
- Volume I (DCR), Appendix D Riverbank Design Technical Memorandum
- Volume I (DCR), Appendix E Cap Design Technical Memorandum
- Volume II (Plans), Appendix N CQA/QCP
  - Section 4.2.3 Clean Material Placement
- Volume III (Specifications/Drawings), Appendix U Specifications (Divisions 31, and 35)
- Volume III (Specifications/Drawings), Appendix V Drawings

2.2.2. Sediment/Soil Removal

The proposed remedy includes dredging and excavation to remove contaminated sediments and riverbank soils from the SIB Project Area. The Pre-Final 90% RD includes in-water sediment removal using mechanical dredging techniques. Riverbank soils remediation includes excavation of contaminated soils prior to placing an engineered cap, backfill, soil for growing medium, and planting with native vegetation.

Details regarding dredge design, riverbank design, supporting engineering analysis, and locations and quantities of dredging are found within the Pre-Final 90% RD documents at the following locations:

- DCR, Section 3.1 Dredging Design
- DCR, Section 3.3 Riverbank Design
- Volume I (DCR), Appendix D Riverbank Design Technical Memorandum
- Volume I (DCR), Appendix H Dredging Design Technical Memorandum
- Volume II (Plans), Appendix N CQA/QCP
  - Section 4.2.1 Dredging/Excavation, Barge Dewatering, and In-Water Transportation

- Volume III (Specifications/Drawings), Appendix U Specifications (Divisions 31, 32, 33, 35)
- Volume III (Specifications/Drawings), Appendix V Drawings

2.2.3. Upland (Off-site) Disposal

There are no available on-site options for transloading or disposal within or near the PHSS. There is one existing transloading facility on the Columbia River located in The Dalles, Oregon. The proposed use of that transloading facility will require barges to travel approximately 97 miles from the SIB Project Area via the Lower Willamette River and the Columbia River.

Details regarding upland (off-site) disposal are found within the Pre-Final 90% RD documents at the following locations:

- DCR, Section 4.1.2 Transportation and Off-Site Disposal Plan
- Volume II (Plans), Appendix N CQA/QCP
  - Section 4.2.1 Dredging/Excavation, Barge Dewatering, and In-Water Transportation,
  - Section 4.2.2 Offload/Disposal of Dredged Materials
- Volume II (Plans), Appendix O Transportation and Off-Site Disposal Plan
- Volume III (Specifications/Drawings), Appendix U Specifications (Division 35)
- Volume III (Specifications/Drawings), Appendix V Drawings

2.2.4. Removal and Installation of Piling and Structures

Removal of derelict piling within the shallow water and active channel margin (ACM) zones of the SIB Project Area is specified as a component of on-site compensatory mitigation and evaluated as part of the Volume 1 (DCR) Appendix C Habitat Impact Evaluation Technical Memorandum. Removal and replacement of the Lagoon Wharf structure is necessary to achieve RAOs. The design for that structural removal and replacement is advancing on a parallel track. Therefore, details about that component of the design are not yet available.

Details regarding removal and installation of piling and structures are found within the Pre-Final 90% RD documents at the following locations:

- DCR, Section 3.5 Structural Design Analysis
- Volume 1 (DCR), Appendix C Habitat Impact Evaluation Technical Memorandum
- Volume I (DCR), Appendix J Structural Design Technical Memorandum
- Volume II (Plans), Appendix N CQA/QCP
  - Section 4.2.5 Structural Monitoring and Inspections
  - WQMP Section 2.9 Removal of Pilings, In-Water Structures, and Debris BMPs
  - WQMP Section 2.10 Installation of Pilings BMPs
- Volume III (Specifications/Drawings), Appendix U Specifications (Division 02 32 00)
- Volume III (Specifications/Drawings), Appendix V Drawings

3.0 POTENTIAL IMPACTS

Appendix L of the PHSS FS includes a discussion of potential impacts of remedial activities. While that discussion addressed potential PHSS-wide impacts associated with the FS alternatives, it remains applicable to the SIB Project Area Pre-Final 90% RD and is incorporated here by reference. SIB Project Area-specific detail is presented here as relevant to supplement the prior discussion of potential impacts presented in Appendix L of the PHSS FS.

3.1. POTENTIAL IMPACTS ON PHYSICAL AND CHEMICAL CHARACTERISTICS OF THE AQUATIC ECOSYSTEM

The proposed remedy for the SIB Project Area will affect the aquatic ecosystem in the following primary ways:

- Removal of contaminated sediment by mechanical dredging and placement of in-water fill material – both activities will discharge contaminants to Waters of the U.S.;
- Placement of engineered caps to contain and isolate in place contaminated sediments. Engineered caps may incorporate activated carbon as an amendment within the chemical isolation layer. The increased concentration of carbon in the sediments may affect chemical processes in the riverbed.

The proposed remedy for the SIB Project Area does not include in-water disposal nor does it include use of a confined disposal facility (CDF).

The potential impacts of the proposed remedy on physical and chemical characteristics of the aquatic ecosystem includes consideration of the following:

- Substrate
- Suspended particulates/turbidity and dissolved oxygen (DO)
- Surface water quality
- Current patterns, water circulation, and normal water fluctuations
- Floodplains

Each of these impact types are discussed in the following sections.

3.1.1. Substrate

Site history and background and existing conditions regarding substrate are discussed in Appendix L of the PHSS FS. That discussion remains relevant and is incorporated here by reference.

The proposed remedy for SIB includes extensive dredging using mechanical dredging equipment. Dredging will change the elevation and material composition of the riverbed substrate, but those changes vary throughout the SIB Project Area. Engineered caps are specified throughout SIB, so dredging impacts on substrate must be considered concurrently with the substrate impacts associated with engineered caps. Dredging will cause a temporary disruption to the substrate throughout most of SIB. Permanent effects of dredging are limited to modification of the riverbed elevation.

Engineered caps are specified for the entire in-water portion of the SIB Project Area. Within the shallow water habitat zone (between water depths of 0 ft [+7.3 ft NAVD88] and 20 ft [-12.7 ft NAVD88] when the river stage is at OLW), final cap surfaces will be constructed by placing a layer of beach mix rounded gravel. This material placement is an impact minimization measure to establish a natural substrate within the shallow water zone. Within the deep water habitat zone (below -12.7 ft NAVD88), engineered caps require an erosion protection layer to prevent erosive forces related to vessel traffic from compromising the integrity and performance of the caps. Gradual deposition of fine sediment will occur within the deep water zone (approximately 1 centimeter per year) restoring some ecological function to deep water benthic habitats. The impacts to deep water substrates will be partially mitigated by placement of clean sand above the erosion protection layer within deep water locations less susceptible to riverbed erosion in response to vessel traffic. Engineered caps will provide a significant beneficial effect on the chemical conditions of the substrate by reducing exposure to contaminants in sediment, porewater, and surface water.

Removal of derelict piles and structures prior to dredging and capping would not significantly alter the substrate. Pile removal within the shallow water zone and ACM is included in the proposed remedy as a component of on-site mitigation.

3.1.2. Suspended Particulates/Turbidity and Dissolved Oxygen

Appendix L of the PHSS FS discussion of RA effects on suspended particulates/turbidity and DO remains current and applicable to the SIB and is incorporated here by reference. Additional details related to SIB-specific observations and design are provided here to supplement the previous discussion.

Remedial activities including dredging, capping, and removal of piles, all have the potential to cause localized, short-term increases in turbidity and decreases in DO. These potential impacts will be managed through implementation of the WQMP included as an attachment to the CQA/QCP (Volume II, Appendix N, Attachment C). The WQMP includes turbidity and DO monitoring during construction and specifies BMPs and contingency corrective measures to address exceedances.

3.1.3. Surface Water Quality

Appendix L of the PHSS FS discussion of RA effects on surface water quality remains current and applicable to the SIB and is incorporated here by reference. Additional details related to SIB-specific observations and design are provided here to supplement the previous discussion.

Remedial activities including dredging, capping, and removal of piles, all have the potential to cause localized, short-term water quality impacts during construction. These potential impacts will be managed through implementation of the WQMP. The WQMP specifies BMPs and contingency corrective measures to address exceedances for standard water quality parameters as well as contaminants potentially released to the water column during dredging and other remedial activities.

Short-term localized effects on water quality are expected during construction. Overall, the remedy will improve long-term water quality by reducing exposure to contaminants in the sediments, porewater, and surface water.

3.1.4. Current Patterns, Water Circulation, and Normal Water Fluctuations

Site history and background and existing conditions regarding current patterns, water circulation, and normal water fluctuations are discussed in Appendix L of the PHSS FS. That discussion remains relevant and is incorporated here by reference. Additional details related to SIB-specific observations and design are provided here to supplement the previous discussion.

The SIB is predominantly a quiescent backwater from the main channel of the Willamette River. Ambient current velocities are driven by tidal exchange and are uniformly less than 0.1 ft per second (ft/sec). The proposed remedy will change the riverbed elevations as a result of dredging and capping. The changes result in a small net increase in the total area of shallow water habitat. Hydrodynamic modeling performed as part of the recontamination analysis determined that the current patterns, water circulation, and normal water fluctuations would be negligibly affected by the changes in riverbed elevation resulting from RA implementation.

3.1.5. Floodplains

The flood impact evaluation (DCR Section 2.2.3) evaluated the potential effects of the proposed remedy on flood rise compared to pre-RA baseline conditions. The evaluation demonstrated that the proposed RA in SIB is not likely to cause unacceptable flood rise based on the specified SIB Project Area post-construction riverbed and riverbank elevations.

Floodplain connectivity is severely degraded throughout the PHSS. The riverbank treatments included in the proposed RA address this to a small degree within the limits of the SIB Project Area by restoring and reconnecting adjacent habitats along much of the SIB shoreline so there is continuity between the riparian zone, ACM, and shallow water zone.

3.2. POTENTIAL IMPACTS ON BIOLOGICAL CHARACTERISTICS OF THE AQAUTIC ECOSYSTEM

Appendix L of the PHSS FS includes a discussion of potential impacts on biological characteristics of the aquatic ecosystem. That discussion remains applicable to the SIB Project Area and is incorporated here by reference. Updated information and SIB Project Area-specific details are provided here to amend and update that prior discussion.

This discussion addresses each of the following components of the biological characteristics of the aquatic ecosystem:

- Threatened and endangered (T&E) species
- Aquatic food web
- Wildlife

3.2.1. Threatened and Endangered Species

EPA completed programmatic consultation with National Oceanographic and Atmospheric Administration (NOAA) National Marine Fisheries Services (NMFS) to address requirements related to Endangered Species Act Section 7(a)(2) (ESA) and Magnuson-Stevens Fishery Conservation and Management Act Essential Fish Habitat. The Biological Opinion (BO) was issued by NOAA-NMFS on May 16, 2025, and it covers the PHSS cleanup activities including the proposed remedy for SIB (NOAA 2025). The BO concluded that "the proposed action is not likely to jeopardize the continued existence of the following species, or result in the destruction or adverse modification of their designated critical habitat." The species considered in the consultation are listed below:

1. Lower Columbia River (LCR) Chinook salmon (*Oncorhynchus tshawytscha*)
2. Upper Willamette River (UWR) Chinook salmon
3. Upper Columbia River (UCR) spring-run Chinook
4. Snake River (SR) spring/summer-run Chinook salmon
5. SR fall-run Chinook salmon
6. Columbia River (CR) chum salmon (*O. keta*)
7. LCR coho salmon (*O. kisutch*)
8. SR sockeye Salmon (*O. nerka*)
9. LCR steelhead (*O. mykiss*)
10. UWR steelhead
11. Middle Columbia River steelhead
12. UCR steelhead
13. Snake River Basin (SRB) steelhead
14. Southern distinct population segment Pacific eulachon (*Thaleichthys pacificus*)
15. Southern distinct population segment green sturgeon (*Acipenser medirostris*)
16. Sunflower sea star (*Pycnopodia helianthoides*)

NMFS also concluded that the proposed action is not likely to adversely affect Southern Resident killer whale (*Orcinus orca)* and their designated critical habitat.

The proposed remedy would have short-term and localized effects on T&E species related to turbidity and resuspension of contaminants during construction. The BMPs identified in the BO are incorporated into the Pre-Final 90% RD as documented in the CQA/QCP (Volume II, Appendix N). The CQA/QCP includes a WQMP that specifies BMPs for specific remedial activities. In-water work will take place during approved in-water work periods, and avoidance and minimization measures will be applied in accordance with the WQMP and CQA/QCP.

The proposed remedy does not include in-water disposal or use of a CDF, so the impacts related to those topics discussed in Appendix L of the PHSS FS do not apply to the SIB Project Area.

The proposed remedy incorporates avoidance, minimization, and mitigation measures in keeping with ROD requirements and as guided by the RDGC. Those measures result in a net positive effect on habitats within the SIB Project Area with priority given to restoring riparian vegetation, restoring substrate and slopes within the ACM, applying beach mix as a final surface to caps placed

within the shallow water zone, and placement of large wood in the ACM to provide habitat complexity and protection for wetland pockets along the shoreline fringe.

As noted in Appendix L of the PHSS FS, "Pacific lamprey ammocoetes are not an ESA-listed species, but they are designated as a species of concern by U.S. Fish and Wildlife Service (USFWS) due to their cultural significance and declining populations." Any ammocoetes present within the benthic habitats of SIB would be disrupted during RA construction as the majority of SIB will be dredged and all of the SIB will be capped. Long-term benefits to Pacific lamprey ammocoetes will result from reducing exposure to contaminants in sediments, porewater, and surface water. Suitable benthic habitat for ammocoets will develop over time as fine sediment is deposited and accumulates within SIB post-RA.

3.2.2. Aquatic Food Web

Appendix L of the PHSS FS includes a discussion of potential impacts on the aquatic food web. That discussion remains applicable to the SIB and is incorporated here by reference. The concluding statement in that prior discussion noted the long-term benefits of the RA with respect to the aquatic food web:

> *"Overall, remedial activities will benefit the aquatic ecosystem by reducing exposure to contaminants in sediment, porewater, and surface water. The most significant predicted improvement would be the reduction in fish and invertebrate tissue of PCBs, dioxin/furans, DDx, and other contaminants. This would indirectly result in a minimization of exposure and potential adverse effects to higher trophic level organisms."*

3.2.3. Wildlife

Appendix L of the PHSS FS includes a discussion of potential impact on wildlife. That discussion remains applicable to the SIB Project Area and is incorporated here by reference.

3.3. POTENTIAL IMPACTS ON SPECIAL AQUATIC SITES

Appendix L of the PHSS FS includes a discussion of potential impacts on special aquatic sites. That discussion remains applicable to the SIB and is incorporated here by reference. Updated information and SIB-specific details are provided here to amend and update that prior discussion.

This discussion addresses each of the following kinds of special aquatic sites:

- Sanctuaries and refuges
- Wetlands
- Mudflats
- Vegetated shallows
- Riffle and pool complexes
- Shorelines and riparian habitats
- Floodplains

3.3.1. Sanctuaries and Refuges

Appendix L of the PHSS FS includes a discussion of potential impact on sanctuaries and refuges. That discussion remains applicable to the SIB Project Area and is incorporated here by reference.

3.3.2. Wetlands

Appendix L of the PHSS FS includes a discussion of potential impacts on wetlands. That discussion remains applicable to the SIB Project Area and is incorporated here by reference. Note that the prior discussion (in the PHSS FS) identified no wetlands within the SIB Project Area. The baseline habitat conditions survey conducted as part of the SIB Project Area Pre-Design Investigation (PDI) also did not identify wetlands within the Project Area.

3.3.3. Mudflats

Appendix L of the PHSS FS includes a discussion of potential impacts on mudflats. That discussion remains applicable to the SIB Project Area and is incorporated here by reference. Note that the prior discussion identified no mudflats within the PHSS. Baseline habitat conditions survey conducted as part of the SIB Project Area PDI did not identify mudflats within the Project Area.

3.3.4. Vegetated Shallows

Appendix L of the PHSS FS includes a discussion of potential impacts on vegetated shallows. That discussion remains applicable to the SIB and is incorporated here by reference. Note that the prior discussion identified no vegetated shallows within the PHSS. The baseline habitat conditions survey conducted as part of the SIB Project Area PDI did not identify vegetated shallows within the Project Area.

3.3.5. Riffle and Pool Complexes

Appendix L of the PHSS FS includes a discussion of potential impacts on riffle and pool complexes. That discussion remains applicable to the SIB and is incorporated here by reference. Note that the prior discussion identified no riffle and pool complexes within the PHSS and offered this explanation:

> *"Because the Willamette River within the Site does not have a steep gradient, and because it is channelized and the shoreline contains extensive modifications, including riprap and seawalls, it is highly unlikely that riffle and pool complexes exist within the Site; therefore, no impacts are anticipated."*

The baseline habitat conditions survey conducted as part of the SIB Project Area PDI confirmed that there are no riffle and pool complexes within the Project Area.

3.3.6. Shorelines and Riparian Habitats

Appendix L of the PHSS FS includes a discussion of potential impacts on shorelines and riparian habitats. That discussion remains applicable to the SIB and is incorporated here by reference.

The proposed remedy for the SIB Project Area incorporates shoreline enhancements into the RD through avoidance, minimization, and on-site mitigation. Riverbanks are remediated by a combination of removal of contaminated soil and regrading of the riverbanks to flatter slopes by placement of a cap and additional fill above the cap to provide a growing medium for riparian vegetation restoration. The proposed remedy specifies native riparian vegetation where feasible, resulting in revegetation of over half of the riverbank area. Wherever feasible and compatible with achieving RAOs, the ACM will be graded to slopes flatter than 5H:1V. Beach mix is specified for final substrate on the surfaces of caps within the ACM and shallow water zones, where practicable. The Habitat Impact Evaluation Technical Memorandum (Volume 1, Appendix C) presents a habitat equivalency analysis (HEA) that maps and quantifies each of these treatments and compares pre-RA baseline conditions to post-RA conditions. Over the long term, the proposed remedy will yield a net improvement in riparian and shoreline habitats within the SIB Project Area.

3.3.7. Floodplains

The flood impact evaluation (DCR Section 2.2.3) evaluated the potential effects of the proposed remedy on flood rise compared to pre-RA baseline conditions. The evaluation demonstrated that the proposed RA in SIB is not likely to cause unacceptable flood rise based on the specified SIB Project Area post-construction riverbed and riverbank elevations.

Floodplain connectivity is severely degraded throughout the PHSS. The riverbank treatments included in the proposed RA address this to a small degree within the limits of the SIB Project Area by restoring and reconnecting adjacent habitats along much of the SIB shoreline so there is continuity between the riparian zone, ACM, and shallow water zone.

3.4. TRANSPORT OF CONTAMINATED SEDIMENTS TO TRANSLOADING FACILITY ON THE COLUMBIA RIVER

Section L3.4 of FS Appendix L discusses potential impacts associated with transport of contaminated sediments to a transloading facility on the Columbia River. That discussion remains applicable to the transport and disposal of contaminated sediments as presented in the Pre-Final 90% RD. There is one existing transloading facility on the Columbia River located in The Dalles, Oregon. The proposed use of that transloading facility will require barges to travel approximately 97 miles from the SIB Project Area.

BMPs and avoidance measures outlined in Section L5 of FS Appendix L are incorporated into the Pre-Final 90% RD. Specifically, barges will be sealed to contain sediments and water, and spill-control equipment will be maintained on board the barges to support immediate response to releases. The transload facility will be required to incorporate secondary containment to prevent contaminated materials from leaving the site during transloading. Material stockpiles at the transload facility will be required to have curbing and sumps to facilitate the collection and handling of runoff.

There are no existing transloading facilities or disposal options located within the PHSS, and there are no existing transloading facilities closer than The Dalles. The specifications for the Pre-Final 90% RD provide conditions and requirements that would allow for the use of a newly developed transload facility should one emerge prior to initiating the RA at the SIB Project Area.

Impacts associated with transport of contaminated sediments to transloading facility on the Columbia River would be effectively mitigated by the BMPs described above that would be applied to barge transport and transloading. However, the long-distance barge transit with the large volume of contaminated sediment requiring transport poses a notable risk and is a large cost driver. Both risk and cost would be effectively reduced and mitigated by a closer transloading or disposal option.

4.0 EVALUATION AND TESTING OF DISCHARGE MATERIAL

The term "discharge material" applies to material placed in Waters of the U.S. including remedy construction materials (e.g., capping, in-water fill, erosion protection layers) and dredged material slated for in-water disposal. The proposed remedy does not include any open-water disposal, nor does it include disposal within a CDF.

The CQAQCP (Volume II, Appendix N) includes a WQMP that specifies the following BMPs and testing requirements for discharge material with specific applicability to capping materials and backfill material to be placed in water:

- Prior to placement, materials will be tested and compared against ROD Table 17 cleanup levels (CULs) for sediment and riverbank. Only materials with concentrations below ROD Table 17 CULs will be used for capping. Specification Section 35 37 10 Engineered Caps provides the detailed requirements for inspection and testing of cap materials.
- Prior to placement, materials will be tested and compared against ROD Table 17 CULs for sediment and riverbank. Only materials with concentrations below ROD Table 17 CULs will be used for backfill. Specification Section 31 00 00 - Earthworks provides detailed requirements for inspection and testing of backfill material.
- RA Performing Parties and the RA Contractor will decide if re-use of dredged or excavated materials below Table 17 CULs will be considered for backfill. Dredged material won't be immediately reused as backfill during the same construction window because testing for ROD Table 17 COCs would take time that would likely exceed in-water work window. However, dredged material that's later confirmed to be below CULs and contains higher organic carbon may be reused in subsequent construction phases.

The specified testing requirements are expected to avoid significant adverse impacts on water quality or biota in the short or long term related to placement of these materials.

5.0 IMPACT AVOIDANCE AND MINIMIZATION MEASURES

The Pre-Final 90% RD integrates impact avoidance and minimization measures throughout all the major elements of the design. CWA Section 404(b)(1) requires actions that affect Waters of the U.S. to apply measures to avoid and minimize impacts, BMPs and engineering controls are incorporated into the RD plans, drawings, and specifications in alignment with the findings of the FS, Appendix L CWA 404(b)(1) analysis, the RDGC, and the ROD. Avoidance and minimization measures are applied within the following categories.

- **Specifying Final Surface Materials** – Wherever feasible and compatible with achieving RAOs, the Pre-Final 90% RD specifies ecologically suitable materials for the finished surfaces within the riparian, ACM, and shallow water habitat zones. Ecologically suitable materials in these zones include "beach mix" gravel and clean sand. The HEA presented in DCR, Appendix C Habitat Impact Evaluation Technical Memorandum, provides a quantitative analysis that compares the pre-RA existing "baseline" substrate conditions within the SIB Project Area to the post-RA substrate and final surface conditions specified in the Pre-Final 90% RD.
- **Riparian Vegetation Replacement** – Wherever feasible and compatible with achieving RAOs, the Pre-Final 90% RD specifies the restoration of vegetation (e.g., native plant communities) on the riverbanks within the riparian and ACM zones. The HEA (DCR, Appendix C) provides a quantitative analysis that compares the pre-RA existing "baseline" riparian vegetation conditions within the SIB Project Area to the post-RA riparian vegetation conditions specified in the Pre-Final 90% RD.
- **Grading of Riverbank and Submerged Slopes** – Final grading of the riverbed and riverbanks was informed by the HEA so that ecologically favorable conditions would be achieved wherever feasible and compatible with achieving RAOs. Specifically, riverbank slopes were modified to a flatter grade where space allowed, slopes within the ACM were graded to be flatter than 5H:1V, and final riverbed elevations were designed to produce a net increase in shallow water habitat area. The HEA (DCR, Appendix C) provides a quantitative analysis that compares the pre-RA existing "baseline" topographic/bathymetric conditions within the SIB Project Area to the post-RA topographic/bathymetric conditions specified in the Pre-Final 90% RD.
- **General Handling of Media and Materials** – The effects of dredging, capping, and placement of fill (e.g., erosion protection layers, clean sand, beach mix gravel) are minimized by specific controls applied during RA within the SIB Project Area and during handling and transport.
- **Adherence to In-water Work Windows** – The Pre-Final 90% RD specifies that the timing of in-water work (e.g., dredging, capping, material placement) avoids peaks in salmonid spawning and migration seasons and other biologically critical periods. The specified construction sequence and seasonal timing complies with the in-water construction periods (i.e., "fish windows") specified by Oregon Department of Fish and Wildlife (ODFW), NMFS, and USFWS. Applicable in-water construction periods at the SIB Project Area are July 1 – October 31 and December 1 – January 31 (ODFW, 2008). On a year-by-year and case-by-case basis, regulator agencies may evaluate and approve some limited flexibility on the approved dates for in-water work. Any potential deviations from the specified in-water work period would be reviewed and approved by appropriate agencies to avoid impacts.

Specific avoidance and minimization measures are discussed in the following sections for major elements of the RD. The CQA/QCP (Volume II, Appendix N) includes a WQMP that specifies BMPs for each of the following remedial activities:

- In-water work period
- Containment devices, work area isolation methods, and fish salvage BMPs

- Spill control, fueling, and maintenance
- Vessel operation BMPs
- Dredging BMPs
- Capping BMPs
- Backfill material requirements
- Riverbank excavation, slope setback, material removal/replacement, and capping BMPs
- Removal of pilings, in-water structures, and debris BMPs
- Installation of pilings BMPs
- Barge loading, transport, and transloading of dredged material BMPs

Section 2.0 of the WQMP presents a comprehensive list and description of the BMPs and controls applied to each of these activities. Excerpts from the WQMP are included in the following sections.

5.1. IN-WATER WORK

The primary minimization measure for in-water work is adherence to the Lower Willamette in-water work period between July 1 and October 31 that applies to work in SIB.

The CQA/QCP (Volume II, Appendix N) specifies monitoring, reporting, and corrective actions that will apply during in-water construction. The CQA/QCP includes a WQMP designed to minimize water quality impacts during in-water work. Specific monitoring and controls for in-water work are listed below.

- Turbidity, DO, and initial chemical constituent monitoring.
- Sediment and contaminant dispersion control measures including limited active work area, managed production rates, environmental dredge buckets.
- Contingency measures and notification procedures to address exceedances or observed or dead species.

See the WQMP for additional detail regarding controls, BMPs, monitoring during construction, and contingency measures for exceedances.

5.2. DREDGING BEST MANAGEMENT PRACTICES

The CQA/QCP (Volume II, Appendix N) includes a WQMP that specifies dredging BMPs. The following text is taken from Section 2.5 of the WQMP.

Article 3.04 Conduct of Work of Specification Section 35 24 20 (Remedial Dredging, Barge Dewatering, and In-Water Transportation) includes required and additional BMPs to be considered. As seen in Article 1.05 of the Specification 35 24 20, material handling and processing will be further developed by the RA Contractor in the Dredging and Excavation Plan of the RA Work Plan (RAWP). BMPs consistent with the National Oceanic and Atmospheric Administration (NOAA) – National Marine Fisheries Service (NMFS) Biological Opinion WCRO-2021-01886 (NOAA, 2025) will also include:

- A strategic dredge sequencing plan developed to minimize the spreading of highly contaminated sediment to adjacent areas and use over-dredge allowance to remove targeted material in a single dredge event.
- The operation employing experienced contaminated sediment dredge operators supervised by professionals experienced in ensuring protocol adherence and utilizing 3-dimensional (3D) sediment visualizations. This 3-D sediment visualization will include an accurate digital terrain model of sediment contamination depth that can be viewed by the operator and supervisor. Operators will also utilize GPS located on the bucket with sub-ft accuracy, and stair-step dredge cuts to reduce sediment sloughing along steeper slopes.
- Efforts to limit sediment resuspension, such as the utilization of closed or environmental buckets, avoiding multiple bucket bites, implementing careful bucket control techniques, and utilizing spuds or anchoring systems to limit the resuspension. If the equipment used is found not to be the best suitable for site conditions, adjustments will be made. A procedure will be in place to halt operations if excessive resuspension is observed, as further discussed in Section 3.
- Examples of BMPs for physical sediment dispersion control include sheet piling, silt curtains, and moon pools.

5.3. BEST MANAGEMENT PRACTICES FOR PLACING CAPPING MATERIALS

The CQA/QCP (Volume II, Appendix N) includes a WQMP that specifies BMPs for placement of capping materials. The following text is taken from Section 2.6 of the WQMP.

Consistent with PBA (Section 2.5.3) (EPA, 2021a), BMPs implemented during in-water capping will include the following:

- Prior to placement, materials will be tested and compared against ROD Table 17 CULs for sediment and riverbank. Only materials with concentrations below ROD Table 17 CULs will be used for capping. Specification Section 35 37 10 Engineered Caps provides the detailed requirements for inspection and testing of cap materials;
- Cap Certification Units will be capped in the same sequence as Dredge Certification Units each season, maintaining a minimum 300-foot separation between dredging and capping;
- Capping confirmation monitoring for accurate placement will be completed using set volume, tonnage, lead line measurements, and bathymetry information or similar;
- Cap placement will be done in lifts to minimize disturbance of each placement, lower the residuals in the topmost layer of the cap and minimize cap depth variability;
- Water quality monitoring will be performed as indicated in Section 3. Responses to specific measurements and actions will be set in place to respond to any triggered actions;
- When possible, work will be performed during low river flows; and
- Where possible, vegetation will be incorporated on riverbank caps.

The CQA/QCP further discusses corrective actions and contingency plan for abnormal occurrences.

5.4. ON-SITE MITIGATION MEASURES FOLLOWING DREDGING AND CAPPING

The Pre-Final 90% RD integrates multiple on-site mitigation measures that align with guidance provided in the ROD and the RDGC as described below.

The Pre-Final 90% RD specifies dredging and capping within the shallow zone that maintains approximate pre-RA riverbed elevations wherever feasible and consistent with desired ecological outcomes. The RD includes some final elevations within shallow areas and within the ACM that do not match pre-RA topography and bathymetry. This is largely the result of flattening slopes on riverbanks, within the ACM, and in the shallow water zone to achieve ecological improvements in those habitats (e.g., slopes flatter than 5H:1V, continuity between habitat zones). The remedy will result in a net increase in the total area of the shallow water zone compared to pre-RA baseline conditions.

Engineered beach mix layer is applied as the surface layer for caps placed in the shallow water areas and on the riverbanks within the ACM. Physical stability analysis of the beach mix material was performed as part of cap design, and it was determined that beach mix sufficiently resists the erosive forces of waves and currents within the shallow zone to protect cap performance.

Native riparian vegetation is specified as a final condition in most of the riparian areas within the SIB Project Area. Caps on riverbanks are designed to provide a sufficient layer of soil to support restoration of native riparian vegetation on most riverbank areas within the SIB Project Area with soil depth great enough to prevent roots from compromising the chemical isolation layer performance.

Derelict piling and cross members will be removed from shallow zone and ACM, and those areas will be capped with final surface composed of beach mix.

Large wood will be placed within the ACM at selected locations to provide localized protection of ACM wetland pockets and add habitat complexity.

The HEA (DCR, Appendix C) maps and quantifies each of these components of on-site mitigation and compares them with pre-RA baseline conditions. Section 6.0 discusses the findings of the HEA used to determine whether additional compensatory mitigation is required or if the avoidance, minimization, and mitigation measures integrated into the Pre-Final 90% RD are sufficient to make the remedy "self-mitigating" as envisioned in the ROD and RDGC.

5.5. BARGE LOADING, TRANSPORT, AND TRANSLOADING OF DREDGED MATERIAL

Appendix L of the PHSS FS discusses transport and offloading of contaminated sediments:

> *"Transport and offloading of contaminated sediments to upland disposal facilities will require several measures and BMPs to avoid release of contaminants to surface waters during any step of transport or transloading."*

The CQA/QCP (Volume II, Appendix N) includes a WQMP that specifies BMPs for barge loading, transport, and transloading of dredged material. The following text is taken from Section 2.12 of the WQMP.

As described in Specification Section 35 24 20.01 (Transloading, Upland Transportation, and Disposal), contaminated sediments, debris, and other contaminated wastes will generally be transported by barge to the transload facility and then may be transferred to trucks for transport to upland disposal facilities. Construction methods and BMPs for barge loading and transport operations include the following in accordance with PBA (Section 2.5.7):

- Barge loading and transport will be completed by utilizing double-hulled bin-barges or flat-deck barges with watertight sideboards and covers so that no discharge of water or suspended sediment occurs during transport;
- Water from dredged materials will be routed to barge- and/or land-based water management systems to remove excess sediments and associated contaminants;
- Barges with dredged sediment will be sealed and monitored to prevent over-filling, overflow, and/or direct discharge to water body;
- Barges transport operations will be confined to designated transit routes; and
- Barges will be routinely visually inspected prior to leaving work areas for sediment potentially adhering to the barges.

Construction methods and BMPs for the transload of dredged material include the following in accordance with PBA (Section 2.5.7.2):

- No dewatering will occur from the barge to the river at the transload facility.
- An impermeable lining will be placed under the bucket travel area to capture any spills. Spills occurring outside of the bucket travel area will be addressed immediately.
- A fully welded, watertight steel fabricated box will be used to provide a large target for the equipment used to transfer the sediments. Box walls will be of sufficient height to eliminate potential for splattering sediment outside of the containments to the sides of trucks or the transfer pad as the transfer bucket opens.
- The transfer of dredged material will be completed to minimize splash and splatter of material.
- The transloading equipment will have a spill apron deployed between the barge and shore during offloading operations to prevent the release of spilled material into the water. This apron will be made of impermeable material with no leaking seams. It will also include a collection system for dripper material, sufficient width, and possible wing wall. Containment measures will be used to capture water running down the apron, and the apron will be able to track tidal fluctuations with the barge.
- Decontamination will occur before moving the crane/excavator, the spill apron, and the bucket.

- Loading of the truck/railcars will take place within an exclusion zone, which will be established to contain any spilled material that may occur while loading.
- Loading will occur following lining construction and establishment of haul routes.
- Vehicles will be washed prior to entering the exclusion zone, and vehicle wash wastewater will be properly collected and disposed of.
- Dust suppression with water misting systems will be utilized.
- Stormwater management facility will have NPDES Industrial Stormwater General permit and a Stormwater Pollution Prevention Plan (SWPPP).

As discussed in Section 2.5, barge loading procedures, material handling and processing will be further developed by RA Contractor in the Dredging and Excavation Plan of the RAWP.

6.0 COMPENSATORY MITIGATION

Appendix L of the PHSS FS discusses compensatory mitigation and establishes the expectation that,

> *"During remedial design, remedial activities and avoidance and minimization measures would be fully developed. Based on those detailed plans, the need for compensatory mitigation projects to address the habitat functions potentially impacted by the remedial activities would be determined."*

The RDGC, in Appendix B Topic 9 – Habitat Mitigation (EPA, 2021b), presents EPA guidance on how to apply a HEA model to perform a quantitative comparison of post-RA habitat conditions to pre-RA baseline habitat conditions. NMFS previously prepared a HEA model for the PHSS in cooperation with the Portland Harbor Trustee Council. The purpose of the quantitative HEA is to evaluate whether the RA is "self-mitigating" through the application of avoidance minimization, and mitigation measures integrated into the RD. If the HEA determines that the RA is not "self-mitigating", additional compensatory mitigation would be required, and the quantity and type of additional mitigation would be determined by the ecological deficit calculated by the HEA model. A quantitative analysis of the Pre-Final 90% RD using the HEA model is presented separately in the Habitat Impact Evaluation Technical Memorandum (DCR, Appendix C), which concluded that the habitat improvements incorporated into the Pre-Final 90% RD would result in a negative HEA score supporting a conclusion that the remedy would require additional compensatory mitigation. Between Draft 50% RD and Pre-Final 90% RD, the HEA model was revised to use a model spreadsheet provided by EPA to ensure the appropriate consideration of time as a component of RA impacts. Specifically, the updated model approach considers the duration of impacts during RA construction and the time required for habitats to mature to full function. The quantitative HEA will be further refined, as needed, as part of the Final 100% RD.

The results of the baseline habitat condition survey included in the PDI ER (HGL, 2024a) are used to inform the development of inputs to the HEA model for pre-RA baseline habitat conditions. Those model inputs include the acreage of habitat units within the SIB Project Area, and HEA habitat values for each of those habitat units developed using Table B9-1 in Appendix B of the RDGC (EPA, 2021b).

Inputs to the HEA model for post-RA habitat conditions were developed based on the RD finished surface conditions superimposed on the map of habitat units. In the same approach used for the baseline scenario, the HEA habitat values for post-RA habitat units were developed for the Pre-Final 90% RD using Table B9-1 in Appendix B of the RDGC.

The HEA model was used iteratively throughout the development of the Pre-Final 90% RD to inform the design team of the ecological effects of specific design decisions and to identify opportunities to effectively apply avoidance, minimization, and mitigation measures integrated into the RD. Intermediate results were used to inform the application of avoidance and minimization measures including specifying natural substrates for final surfaces, modifying riverbank and submerged slopes, installing features to provide habitat complexity within the ACM, removing derelict piles, and restoring native vegetation communities in the ACM and riparian zones.

The HEA demonstrates that Pre-Final 90% RD is expected to result in a negative DSAY score that reflects a net impact to aquatic resource functions. Mitigation will be required to address those impacts such that the RA combined with that mitigation would result in "no net loss" of aquatic resource functions. See DCR, Appendix C to review the quantitative HEA. The analysis includes maps and quantities of the areas and locations where avoidance, minimization, and mitigation measures are applied within the RD.

7.0 ANALYSIS OF PRACTICABLE ALTERNATIVES PURSUANT TO SITE CRITERIA

Appendix L of the PHSS FS established that the alternatives evaluation documented in the PHSS fulfilled the CWA Section 404(b)(1) requirement for evaluation of practicable alternatives with respect to the remedial alternatives. The Appendix L discussion of practicable alternatives focused on evaluating disposal alternatives comparing on-site CDF options with transport to upland disposal facilities.

The Pre-Final 90% RD for the SIB Project Area does not include development or use of an on-site CDF. A single existing transload facility located in The Dalles, Oregon, was evaluated and incorporated into the RD as a means of transporting contaminated sediments and soils to an upland disposal facility. The analysis of practicable alternatives in Appendix L of the PHSS FS concluded that the upland landfill options are constructed and operating and are therefore technically feasible and administratively feasible.

8.0 FACUTAL DETERMINATIONS

Factual determinations made for each component of the aquatic ecosystem evaluated are summarized in the following sections. These factual determinations refer back to the preliminary factual determinations published in Appendix L of the PHSS FS and provide SIB Project Area-specific information from the Pre-Final 90% RD to amend and support those determinations as applied to the SIB.

8.1. PHYSICAL SUBSTRATE DETERMINATIONS

Appendix L of the PHSS FS included the following physical substrate determinations:

> *"Remedial activities, including dredging, capping, in-situ treatment, ENR, removal and installation of piles and structures, and disposal of contaminated sediments in a CDF, will alter the material composition, slope, and elevation of the physical substrate. Elevation, slope, and substrate would be restored to the extent possible, and the placement of clean sand residuals cover and/or beach mix will provide an improvement over current physical substrate conditions in some locations by replacing anthropogenic debris or large rock with sand and/or gravel. In areas where armoring is required, adverse impacts to substrate would occur; however, re-deposition of fine-grained material in capped and armored areas is anticipated to occur over time, making the armored areas similar in surface grain size to non-armored areas. Compensatory mitigation to replace lost habitat and forage area from the placement of armor stone would be required to replace lost habitat and forage area and to compensate for other lost functions such as flood capacity. In shallow areas, beach mix will be used as much as possible for armoring and as the top layer of caps to provide appropriate substrate habitat for colonization by benthic organisms."*

The remedial activities specified in the Pre-Final 90% RD include dredging, capping, fill placement, and removal and installation of piles and structures that would alter the material composition, slope, and elevation of the physical substrate. Impacts are avoided, minimized, and mitigated by application of avoidance and minimization measures including specifying natural substrates for final surfaces wherever feasible, modifying riverbank and submerged slopes, installing features to provide habitat complexity within the ACM, removing derelict piles, and restoring native vegetation communities in the ACM and riparian zones. The HEA (DCR, Appendix C) presents a quantitative analysis that compares pre-RA baseline conditions to post-RA conditions and accounts for the effects of time on aquatic resource functions. The HEA demonstrates that Pre-Final 90% RD is expected to result in a negative DSAY score that reflects a net impact to aquatic resource functions. Mitigation will be required to address those impacts such that the RA combined with that mitigation would result in "no net loss" of aquatic resource functions. Although the proposed remedy will alter physical substrates, the specified final surface substrates combined with the other avoidance, minimization, and mitigation measures described above will ensure a net positive effect on physical substrates within the SIB.

8.2. WATER CIRCULATION AND FLUCTUATION DETERMINATIONS

Appendix L of the PHSS FS included the following water circulation and fluctuation determinations:

> *"Following dredging in shallow areas, elevations would be restored to pre-dredge conditions. The analysis presented in Appendix P indicates that impacts from these activities are anticipated to be negligible."*

The Pre-Final 90% RD includes some final elevations within shallow areas and within the ACM that do not match pre-RA topography and bathymetry. This is largely the result of flattening slopes on riverbanks, within the ACM, and in the shallow water zone to achieve ecological improvements in those habitats (e.g., slopes flatter than 5H:1V, continuity between habitat zones). The remedy would result in a net increase in the total area of the shallow water zone. The deviations from restoring shallow water elevations to pre-dredge conditions will have a negligible effect on water circulation and fluctuations.

A flood rise evaluation was performed on the Pre-Final 90% RD to ensure compliance with regulatory requirements for flood rise management. See Section 2.2.3 of the Design Criteria Report. That analysis demonstrated that the proposed RA in SIB is not likely to cause unacceptable flood rise based on the anticipated SIB post-construction elevations.

8.3. SUSPENDED PARTICULATES AND TURBIDITY DETERMINATIONS

Appendix L of the PHSS FS included the following suspended particulates and turbidity determinations:

> *"Impacts on water quality are anticipated to be greatest from debris removal and dredging compared to other remedial activities. Turbidity increases and DO decreases during debris removal and dredging are expected to be limited, short-term, and localized and would be minimized with the implementation of BMPs and avoidance and minimization measures described in Section L5. Water quality parameters would be monitored, corrective measures taken if levels exceed regulatory thresholds established for the proposed remedial alternatives."*

SIB is predominantly a quiescent backwater set back from the main Willamette River channel. Currents within SIB are driven primarily by tidal exchange with ambient current velocities uniformly lower than 0.1 ft/sec. The potential impacts of turbidity and suspended particulates are mitigated by the combination of weak currents, limited active work areas, production rates, dredging BMPs, and water quality monitoring during construction.

The Pre-Final 90% RD specifies water quality monitoring (including turbidity monitoring) during construction with contingency corrective actions defined in the WQMP attachment in the CQA/QCP (Volume II, Appendix N). These elements of the Pre-Final 90% RD ensure that the site-wide suspended particulates and turbidity determinations published in Appendix L of the PHSS FS apply to the SIB Project Area.

8.4. WATER QUALITY DETERMINATIONS

Appendix L of the PHSS FS included the following water quality determinations:

> *"Physical disruption of the contaminated sediments during debris removal and dredging could cause a temporary increase in dissolved phase concentrations of some chemicals in the vicinity of dredging activities, resulting from resuspension of contaminated sediments, desorption of the contaminants from sediment particles to pore water, and release of contaminated pore water into surface water. Short-term increases in water column concentrations is expected to occur intermittently during*

> *the duration of the dredging and dissipate when dredging ceases. Water quality parameters will be monitored corrective actions implemented if levels exceed regulatory thresholds established for the proposed remedial alternatives."*

The Pre-Final 90% RD applies BMPs to protect water quality and specifies water quality monitoring during construction with contingency corrective actions defined in the WQMP attachment in the CQA/QCP (Volume II, Appendix N). These elements of the Pre-Final 90% RD ensure that the site-wide water quality determination published in Appendix L of the PHSS FS applies to the SIB Project Area.

8.5. AQUATIC ECOSYSTEM AND ORGANISM DETERMINATIONS

Appendix L of the PHSS FS identified temporary and localized adverse impacts on the aquatic ecosystem:

> *"Dredging activities will have temporary and localized adverse impacts on the aquatic ecosystem and organisms in the immediate dredging plume area. Remedial activities that disturb the sediment surface will temporarily remove the biologically active zone and associated benthic communities. Recovery times for benthic communities following remedial activities are expected to be on the order of months. In many areas, the physical and chemical improvement in substrate type as a result of the removal of contamination and placement of the dredge residuals layer may promote a more productive benthic community through recolonization on uncontaminated material."*

The Pre-Final 90% RD specifies placing caps throughout the SIB Project Area. Final substrate surface for caps in shallow water and the ACM will be composed of beach mix to minimize long-term impacts of the remedy in those zones. Caps located in the deep water zone require an erosion protection layer to ensure scour from vessel traffic does not interfere with remedy performance. Much of the deep water zone will have angular rock at the surface upon completion of the RA. Fine sediments are expected to accumulate slowly (~1 centimeter per year) eventually restoring a natural substrate layer within portions of the deep water zone.

The remedy will have short-term and long-term impacts on aquatic habitats and species. However, the Pre-Final 90% RD incorporates avoidance, minimization, and mitigation measures (i.e., final substrate composition, slopes less than 5H:1V, removal of derelict piling, restoration of native vegetation on riverbanks) to offset those impacts. The HEA (DCR, Appendix C) quantitatively evaluated the effects of the remedy on the aquatic ecosystem with final substrate composition acting as a key driver of aquatic impacts. The HEA considered the temporal effects of RA implementation and the time required for habitats to reach full function after RA completion. The HEA demonstrated that the application of avoidance and minimization measures within the SIB Project Area would have a net impact on aquatic resource functions quantified as a negative DSAY score. Mitigation will be required to address those impacts such that the RA combined with that mitigation would result in "no net loss" of aquatic resource functions.

8.6. DETERMINATION OF CUMULATIVE EFFECTS ON THE AQUATIC ECOSYSTEM

Cumulative impacts are defined by 40 CFR 230.11(g)(1) as:

> *"the changes in an aquatic ecosystem that are attributable to the collective effect of a number of individual discharges of dredged or fill material. Although the impact of a particular discharge may constitute a minor change in itself, the cumulative effect of numerous such piecemeal changes can result in a major impairment of the water resources and interfere with the productivity and water quality of existing aquatic ecosystems".*

Appendix L of the PHSS FS evaluated cumulative effects and concluded:

> *"The remedial activities will not result in significant detrimental cumulative impacts on the aquatic ecosystem. Although short-term adverse effects from implementation of remedial activities are expected, they would result in long-term benefits to the aquatic ecosystem by reducing exposure to contaminants in sediment, porewater, and surface water. The remedial action and compensatory mitigation, to be defined in the ROD and refined during remedial design, are expected to result in "no net loss" of aquatic resource functions."*

The HEA (DCR, Appendix C) presents a quantitative analysis that compares pre-RA baseline conditions to post-RA conditions and accounts for the effects of time on aquatic resource functions. The HEA was performed iteratively during design development with intermediate results used to inform the application of avoidance and minimization measures including specifying natural substrates for final surfaces, modifying riverbank and submerged slopes, installing features to provide habitat complexity within the ACM, removing derelict piles, and restoring native vegetation communities in the ACM and riparian zones. The HEA demonstrates that Pre-Final 90% RD is expected to result in a negative DSAY score that reflects a net impact to aquatic resource functions. Mitigation will be required to address those impacts such that the RA combined with that mitigation would result in "no net loss" of aquatic resource functions.

8.7. DETERMINATION OF SECONDARY EFFECTS ON THE AQUATIC ECOSYSTEM

Appendix L of the PHSS FS determined that secondary effects on the aquatic ecosystem "are limited to other actions in the aquatic environment that are indirectly related to implementation of the action, such as erosion or downstream sedimentation." The Pre-Final 90% RD presents a remedy designed so that it would not contribute to erosion or downstream sedimentation. SIB is predominantly a quiescent backwater set back from the main Willamette River channel. Currents within SIB are driven primarily by tidal exchange with ambient current velocities uniformly lower than 0.1 ft/sec. The potential for downstream erosion or sedimentation is prevented by the combination of weak currents, limited active work areas, production rates, BMPs, and water quality monitoring during construction.

9.0 REVIEW OF CONDITIONS FOR COMPLIANCE

Appendix L of the PHSS FS reviewed the conditions for compliance. That discussion remains applicable to the SIB Project Area and is incorporated here by reference. The two conditions for compliance are (1) practicability, and (2) compliance with pertinent legislation.

9.1. AVAILABILITY OF PRACTICABLE ALTERNATIVES

Appendix L of the PHSS FS discussed the availability of practicable alternatives and addressed the four general conditions that must be met for compliance:

1. practicability;
2. compliance with the ESA;
3. protections for water quality and human uses; and
4. compliance with the avoidance, minimization, and compensatory mitigation requirements.

The Pre-Final 90% RD for the SIB Project Area was developed in accordance with the ROD and the RDGC in a way that is consistent with the prior discussion in Appendix L of the PHSS FS.

9.2. COMPLIANCE WITH PERTINENT LEGISLATION

Appendix L of the PHSS FS briefly discussed compliance with Executive Orders and pertinent legislation:

> *"Alternatives B through I are expected to comply with the Executive Order 11988 (Floodplain Management) and Executive Order 11990 (Protection of Wetlands) and Oregon Environmental Cleanup Laws."*

The Pre-Final 90% RD for the SIB Project Area was developed in accordance with the ROD and the RDGC in a way that is consistent with the prior discussion. This conclusion is further supported by the Flood Impact Evaluation (Section 2.2.3 of the Design Criteria Report), which concluded that the proposed RA in SIB is not likely to cause unacceptable flood rise based on the post-construction elevations.

10.0 FINDINGS

Appendix L of the PHSS FS found that "the proposed remedial alternatives are the least environmentally damaging practicable alternative that meets the project purpose and need. There are no practicable alternatives that avoid waters of the U.S. due to the location of the contaminated sediments." The Pre-Final 90% RD for the SIB Project Area was developed in accordance with the ROD and RDGC, and is a site-specific component of the overall remedy for PHSS. Specific aspects of the SIB RD are highlighted below to support the applicability of the prior findings.

Avoidance, minimization, and mitigation were integrated into the Pre-Final 90% RD by using the HEA model iteratively during design development. The HEA model was used to evaluate specific design decisions related to surface substrate material specification; riverbank design to accommodate maximum extent of native riparian vegetation restoration; grading of slopes within

riparian, ACM, and shallow water zones; removal of derelict piles; and shoreline wetlands within the ACM. The results of the HEA support the conclusion that this was an ecologically effective application of the ROD and RDGC guidance.

Disposal of dredged sediments will occur at upland locations and will not use a CDF or other in-water disposal. The SIB Project Area Pre-Final 90% RD therefore avoids aquatic impacts associated with a CDF that were contemplated as part of the CWA Section 404(b)(1) analysis reported in Appendix L of the PHSS FS.

A quantitative analysis of the Pre-Final 90% RD using the HEA model is presented separately in the Habitat Impact Evaluation Technical Memorandum (DCR, Appendix C). The HEA concluded that the habitat improvements incorporated into the Pre-Final 90% RD would result in a negative DSAY score supporting the conclusion that the remedy would need additional compensatory mitigation to address unavoidable impacts.

DREDGING DESIGN TECHNICAL MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
SWAN ISLAND BASIN PROJECT AREA, CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

This Dredging Design Technical Memorandum (DDTM) presents a summary of dredging design efforts for the Pre-Final 90% Remedial Design (Pre-Final 90% RD) for the Swan Island Basin (SIB) Project Area within the Portland Harbor Superfund Site (PHSS) in Portland, Multnomah County, Oregon. The HydroGeoLogic, Inc. (HGL) team performed the work on behalf of the SIB RD Group based on the requirements of the PHSS Record of Decision (ROD) (EPA, 2017) and the Administrative Settlement Agreement and Order on Consent (EPA, 2021). The data used in this DDTM were collected in accordance with the final Pre-Design Investigation (PDI) Work Plan (HGL, 2022), and were reported in the PDI Evaluation Report (ER), which the U.S. Environmental Protection Agency (EPA) approved in January 2025 (HGL, 2024a).

The objective of this DDTM is to provide an overview of the analysis performed to develop the Pre-Final 90% RD dredging design. Dredging design was driven primarily by information and criteria developed in the Basis of Design Report (BODR) (HGL, 2024b), navigation depth requirements, and capping considerations described in the Pre-Final 90% RD Cap Design Technical Memorandum (CDTM) (Volume I, Appendix E).

Section 1 discusses navigation depth requirements that were incorporated into the dredging design. Section 2 describes the incorporation of cap design considerations into the dredging design. Section 3 presents the evaluation of technology assignments. Section 4 discusses constructability considerations in the dredging design shown in the Pre-Final 90% RD Design Drawings.

1.0 NAVIGATION DEPTHS

Between August 2022 and February 2023, interviews were conducted with shoreline facility owners/operators in the SIB Project Area. The interviews included requests for specific navigation depths adjacent to existing facilities. Navigation depths that generally aligned with historically maintained depths were applied to guide the development of the dredge design. Further analysis of dredging impacts on slopes and structures, as well as further engagement with owners/operators in the SIB Project Area, were conducted in 2025 to develop a refined understanding of appropriate navigation depths. Future maintenance dredging (FMD) would occur in these SIB navigation areas.

The updated information collected in 2025 was incorporated into analysis of dredging and capping extents. After incorporation of the revised navigational and operational needs, the design team modified the navigation area extents presented in the BODR (HGL, 2024b) to include operationally prescribed dredge to remedial action level (RAL) areas, align with current mooring and berthing practices, and reflect input from facility owners and operators. Figure 1-1 shows the

Pre-Final 90% RD navigation depths and maneuvering areas. The purpose of the figure is to demonstrate the minimum navigation depths that must be provided as part of the design.

2.0 CAPPING CONSIDERATIONS AFFECTING DREDGING

Cap design details are provided in the CDTM (Volume I, Appendix E). The Pre-Final 90% dredging design assumes a total 3-ft cap thickness will be placed after dredging in SIB navigation areas, and a 1-ft clearance will be left above the top of the cap to preclude damage to the cap during FMD. Therefore, post-dredging elevations be at least 4 ft below the navigation elevation to accommodate both the cap and the FMD clearance. One foot of FMD clearance above the top of the cap is sufficient to preclude damage to the cap during maintenance dredging, because precision dredging operations with mechanical equipment can be prescribed at tolerances less than 6 inches. This construction tolerance differs from tolerances used in the cost comparison exercise described in Section 3 because the cost comparison exercise is intended to use conservative assumptions for costs of each alternative.

3.0 DREDGING DESIGN

The Pre-Final 90% RD dredging design considered three areas of SIB:

1. Slopes/banks, where geotechnical slope stability and structural stability governed the dredging and capping;
2. Spudding/anchoring areas (ongoing operations), where Dredge to RAL was required because caps cannot accommodate these types of disturbances. Engagements with shoreline facility owners/operators in the SIB Project Area prompted the addition of four such areas; and
3. Open water, where a choice could be made between dredging to remove all sediment with concentrations of contaminants of concern (COCs) exceeding RAL (Dredge to RAL), or placing a cap.

All underwater slopes and riverbanks in the SIB Project Area will undergo active remediation. Slope/riverbank remediation includes removal of debris, riprap, vegetation, and soil and sediment on the slopes as needed to achieve pre-capping design grades. Some places will require backfill to meet pre-capping grades. After necessary excavation or backfill on slopes/riverbanks to meet design grades, the slope/riverbank will be capped (either armored or planted depending on elevation and location).

For the open water areas only, a cost comparison analysis was conducted on a gridded map of the open water areas of the site (flat, in-water areas away from slopes), for three different remedial technology alternatives. The sole purpose of this exercise was to determine the lowest-cost feasible alternative, i.e. whether it was less expensive to install a cap rather than Dredge to RAL. The result of this cost comparison analysis is a map of lowest-cost alternatives in the open water areas; however, this map does not yet represent the actual dredging design.

Alternatives were compared in each cell of a 10-ft by 10-ft regular grid covering the entirety of SIB. The size of these analysis cells does not affect the analysis results. The cost comparison

analysis included two different cap types in the Pre-Final 90% RD which were prescribed based on design requirements (e.g., shallow water, vessel traffic).

Design considerations such as shallow water habitat impacts, flood rise impacts, and PTW threshold exceedances were considered in the design of the alternatives (e.g., the cap layering and materials) prior to this cost comparison being performed, and therefore were not a factor in this open water area cost comparison exercise. After this initial lowest-cost alternatives map was developed for the open water areas, the map was refined further based on additional practical design considerations, primarily slope stability (e.g., avoiding dredging in open water adjacent to slopes and causing instability).

3.1. REMEDIATION TECHNOLOGIES EVALUATED IN OPEN WATER AREAS

Three remediation technologies were evaluated for open water areas during the Pre-Final 90% RD: Dredge to RAL, Dredge and Cap, and Cap Only. There are two cap types in the Pre-Final 90% RD: Cap Type 1 consists of 1 ft of sand amended with granular activated carbon (GAC), followed by 2 ft of rounded gravel (habitat mix) which serves as both erosion protection layer (EPL) and habitat layer. Cap Type 2 consists of 1 ft of sand amended with GAC, followed by 18 inches of angular rock as the EPL, followed by 6 inches of sand as the habitat layer. Additional details regarding the three technologies evaluated in the cost comparison exercise for open water areas are listed below:

1. **Dredge to RAL:** This alternative entails dredging 2 ft below the bottom vertical boundary of the Sediment Management Area (SMA) to remove COCs at concentrations exceeding RALs. Contingency re-dredging was not included in the cost comparison due to uncertainty as to whether it will be required, where it would be required, and to what depth it will be required. Dredging 2 ft below the SMA reduces the risk that this time-consuming re-dredging process will be required in the short time periods available for construction. A 1-ft Residuals Management Layer (RML) of clean sand would be placed after dredging to RAL. Also, after placement of the RML, backfill with imported sand is required in all Dredge to RAL areas besides the dry docks (which are historic deep spots), because leaving deep spots in the final project surface is not allowed by EPA due to future water quality concerns. Backfill creates significant additional costs.
2. **Dredge and Cap:** This alternative entails dredging as needed to achieve appropriate navigation depths and 1-ft FMD clearance. After dredging, the 3-ft cap (either Type 1 or Type 2) will be placed for chemical isolation, erosion protection, and habitat. Material type and assumptions regarding additional material placed within acceptable tolerances are described in Section 3.3. Capping solutions incur additional costs for Operations and Maintenance (O&M), and monitoring, which have been included.
3. **Cap Only:** This alternative entails placing the same 3-ft cap (either Type 1 or Type 2) noted above for the Dredge and Cap alternative. The Cap Only alternative would be applied in areas with sufficient existing depth for cap placement while still accommodating navigation and FMD clearance, or in areas with no navigation depth. No cost comparison was made between Cap Type 1 and 2 because they are intended for different locations. If selected, the Cap Only alternative would apply Cap Type 1 near the head of SIB (shallow

water, minimal vessel traffic), and Cap Type 2 in SIB navigation areas. Capping solutions incur additional costs for O&M, and monitoring, which have been included.

3.2. TECHNOLOGY COST ANALYSIS METHOD FOR OPEN WATER AREAS

The remedial technology cost analysis uses a logic process applied to each cell within a 10-ft by 10-ft grid of the open water areas in the SIB Project Area. For the purposes of this analysis, "open water areas" are defined as in-water areas that are not on the lower riverbank slopes or underneath over-water structures. Figure 3-1 shows the logic process. In each cell, the bed elevation, SMA depth, navigation depth, and unit costs were used to compute the cost of applying each of the three remediation technologies. The lowest-cost technology is then assigned to each cell of the open water areas by applying the following specific logic steps (text description of the process shown in Figure 3-1):

1. Identify cells outside the SIB navigation areas (i.e. cells without FMD). For each cell in this filtered set:
    a. Calculate the total cost of the Cap Only technology based on cap volume, cap area, and unit costs for cap O&M, materials and placement (see Section 3.3).
    b. Calculate the required dredge volume and backfill volume for the Dredge to RAL technology from the existing bed elevation, the SMA depth, and the required clearance and tolerances.
    c. Calculate the total cost of the Dredge to RAL technology based on the required dredge volume (previous step), the required RML volume, the required backfill volume, and the associated unit costs.
    d. Assign whichever technology is more cost-effective. Populate the conceptual technology assignment, cost (per cell), dredge volume, backfill volume, cap volume, cap area, post-dredge bathymetric surface, and post-cap bathymetric surface maps accordingly.

2. Identify cells in SIB navigation areas (cells with FMD). For each cell in this filtered set:
    a. Determine if Cap Only technology is viable by adding the cap thickness and placement tolerance to the existing bed elevation and comparing the resulting depth against the prescribed navigation depth plus the 1 ft FMD clearance. If Cap Only technology is viable:
        i. Calculate the total cost of the Cap Only technology based on cap volume, cap area, and unit costs for cap O&M, materials and placement.
        ii. Calculate the required dredge volume and backfill volume for the Dredge to RAL technology from the existing bed elevation, the SMA depth, the required clearance and tolerances.
        iii. Calculate the total cost of the Dredge to RAL technology based on the required dredge volume (previous step), the required RML volume, the required backfill volume, and the unit costs.

iv. Assign the lower-cost technology. Populate the conceptual technology assignment, cost (per cell), dredge volume, backfill volume, cap volume, cap area, post-dredge bathymetric surface, and post-cap bathymetric surface maps accordingly.

b. If Cap Only technology is not viable:

i. Calculate the required dredge volume for the Dredge and Cap technology based on the existing bed elevation, the required navigation depth, the cap thickness and placement tolerance, and the FMD clearance.

ii. Calculate the total cost of the Dredge and Cap technology based on the required dredge volume (previous step), the cap volume, cap area, and the unit costs for dredging, handling, and cap O&M, materials and placement (Section 3.3).

iii. Calculate the required dredge volume and backfill volume for the Dredge to RAL technology from the existing bed elevation, the SMA depth, and the required clearance and tolerances.

iv. Calculate the total cost of the Dredge to RAL technology based on the required dredge volume (previous step), the required RML volume, the required backfill volume, and the unit costs.

v. Assign whichever is more cost-effective. Populate the conceptual technology assignment, cost (per cell), dredge volume, backfill volume, cap volume, cap area, post-dredge bathymetric surface, and post-cap bathymetric surface maps accordingly.

3. Identify cells (if any exist) where Dredge to RAL technology is selected as the lowest-cost technology (from 2b above), but the resulting surface (SMA - 2ft clearance + 1ft RML) violates the 1-ft FMD clearance. For these cells:

a. Calculate the required dredge volume and backfill volume for the Dredge to RAL technology based on the existing bed elevation, the navigation depth, the RML thickness and placement tolerance, and the 1-ft FMD clearance.

b. Update the cost (per cell), dredge volume, backfill volume, post-dredge bathymetric surface, and post-cap bathymetric surface maps accordingly.

Note that Step 3 above never results in a change in technology assignment that was made during Step 2, since the RML is less expensive than the standard cap (Cap Type 1 or 2).

3.3. ANALYSIS ASSUMPTIONS

The analysis includes the following assumptions for the purposes of the cost calculations when applying each technology option in the in-water areas:

- Cap Type 1 (for Dredge and Cap, and Cap Only technologies):
  - 1-ft layer sand amended with GAC, with 0.5-ft paid over-placement

  - 2-ft layer rounded gravel (habitat mix), with no paid over-placement (assume +6/-6-inch construction tolerance)
  - Total assumed cap thickness for cost comparison purposes: 3.5 ft
- Cap Type 2 (for Dredge and Cap, and Cap Only technologies):
  - 1-ft layer sand amended with GAC, with 0.5-ft paid over-placement
  - 1.5-ft layer angular rock, with no paid over-placement tolerance (assume +6/-6-inch construction tolerance)
  - 0.5-ft layer sand, with no paid over-placement (assume +3/-3-inch construction tolerance)
  - Total assumed cap thickness for cost comparison purposes: 3.5 ft
- RML: 1-ft layer sand, with 0.5-ft paid over-placement tolerance
- Backfill: sand fill required to meet surrounding grade and eliminate isolated deep spots
- FMD Clearance: 1 ft below specified navigation depth
