- Dredge to RAL Target Depth: 2 ft below SMA
- Over-Dredge Tolerance: 1-ft paid over-dredging (applies to Dredge to RAL and Dredge and Cap alternatives)
- Cap O&M and monitoring: the Pre-Final 90% RD cost estimate includes approximately $15M for 22 O&M and monitoring events over 100 years, for the entire SIB project. Some items in the O&M costs are not appliable to this in-water technology cost comparison (e.g., vegetation O&M and monitoring), but they were also applied as O&M costs associated with the capping solutions for conservatism. Based on the approximate total cost of $15M for the entire SIB Project Area (approximately 5.8M square feet), the total O&M cost for open water areas (approximately 4.3M square feet) was assumed to be reduced linearly on an area basis for the purposes of this cost comparison, to approximately $11.1M. The $11.1M total O&M and monitoring cost would be incurred if capping was performed everywhere outside the operationally prescribed Dredge to RAL areas (approximately 3.5M square feet), resulting in a unit cost of $3.20 per square foot for O&M and monitoring of a capping alternative. This unit cost for capping was then added to the cost of either Dredge and Cap, or Cap Only, for comparison with costs for the Dredge to RAL alternative.

Unit costs for dredging and capping are listed in Table 3-1. These unit costs were extracted from the cost model reported in the Cost Analysis Technical Memorandum (Volume I, Appendix K).

3.4. RESULTS AND OBSERVATIONS

Results of the cost comparison analysis for the open water areas included dredging volumes, cap material volumes, costs, and COC inventory removed, for each of the three alternatives. Figure 3-2 shows the initial cost-optimized remedial technologies, along with the operationally prescribed Dredge to RAL areas shown in grey (where the cost analysis was not performed). Figure 3-2 shows that Dredge and Cap and Cap Only are the most cost-effective alternatives over most of the open water areas. Dredge to RAL (blue areas in Figure 3-2) is the most cost-effective option only within small slivers less than 100 ft in width, primarily located near the toe of slopes at the U.S. Coast

Guard (USCG) Pier, The Marine Consortium, Inc. (MC) Pier, Lagoon Wharf, and Pier A. After review of these areas outside operationally prescribed Dredge to RAL area, the Dredge to RAL alternative was eliminated from these areas for the following reasons:

1. These narrow slivers are surrounded by capping areas. Areas not shown with a technology assignment in Figure 3-2 (outside the navigation areas) are already being capped (chemical isolation under revetments), so these are small, isolated areas. Separate individual Dredge to RAL designations in these areas creates more construction complexity and inefficiency, and leaves a gap in chemical isolation which creates additional risk;
2. Follow-on construction associated with Dredge to RAL, including contingency re-dredging and the required sampling, testing, and confirmation, combined with potential for the process to be repeated, represents a significant cost risk associated with the Dredge to RAL alternative, especially given the short in-water work period in SIB. Under capping solutions, the removal of requirements for contingency re-dredging and additional sampling and testing reduces the RA implementation schedule, which will result in lower overall cost and impact to businesses operating in SIB; and
3. The design remains protective of human health and the environment.

Figure 3-3 shows the remedial technologies assigned in the Pre-Final 90% RD, after these practical modifications. Figure 3-4 shows the required dredging depths (distances below existing grade) in the Pre-Final 90% RD. Note that in Figure 3-2 through 3-4, slopes/riverbank areas are not represented, since this analysis was performed only in open water areas.

Figure 3-5 shows areas in which the final post-dredging elevations extend to the bottom of the SMA (vertical extent of contamination), potentially removing known sediment with COC concentrations exceeding RALs. However, in the operationally prescribed Dredge to RAL areas, contingency re-dredging may be required in areas where dredging did not completely remove contaminants to the level required. The locations where contingency re-dredging may be needed cannot be reasonably anticipated.

4.0 DREDGING CONSTRUCTION CONSIDERATIONS

This section contains an overview of the various dredging considerations and criteria used to develop the dredging component of the Pre-Final 90% RD. The dredging design is not intended to be prescriptive in terms of RA Contractor means and methods, but provides an overview of the likely dredging methods to be used.

4.1. HYDRAULIC AND MECHANICAL DREDGING

This section discusses methodology for hydraulic and mechanical dredging, including details of how these methods apply to SIB Project Area considerations. The section then provides a rationale for recommending mechanical over hydraulic dredging.

The most common hydraulic dredger is a cutter-head suction dredger. A rotating cutter head breaks up the dredge material and creates a vacuum to force the slurry (composed of only 10 to 20% solids) through a pressurized floating pipeline connected to the transload site. Water entrained in the slurry would require treatment prior to being discharged back into the river or otherwise

disposed of. The floating pipeline, an integral component of hydraulic dredging, poses a barrier to marine vessel traffic. In addition, the cutter head dredger is not designed to operate effectively in the presence of debris which has the potential to create blockages within the pipeline. Even small debris (greater than 6 inches), which would be prohibitive (both financially and technologically) to locate and remove prior to dredging, can plug a smaller hydraulic dredge (USACE, 2008). Debris that is encountered will likely negatively impact on dredging production rates, and cause mechanical failures. In addition, dredging may not commence until a crane with a clamshell bucket, or similar, is used to remove the debris. Hydraulic dredging does have slightly more favorable sediment resuspension and contaminant release controls (sediment controls) than mechanical dredgers. However, this only applies to plain suction, pneumatic, specialty, or diver operated hydraulic dredgers. A conventional cutterhead, swinging ladder cutterhead, and horizontal auger hydraulic dredgers have less favorable performance in the same categories when compared to mechanical dredging.

The hydraulic dredger is connected to the transload site during operation, thus requiring the transload site to be within or close to the SIB Project Area. At the time of the 90% Dredging Design, potentially viable transload sites within or close to the SIB Project Area were not identified. Based on the long-term impact on waterway users, and due to the inability to accommodate encountered debris that is not removed as part of pre-dredge removal efforts, and the lack of availability of a suitable transload site, hydraulic dredging is not currently recommended for the SIB Project Area.

Mechanical dredging removes material with the use of mechanical force using a bucket or excavator. The bucket is lowered down to the sediment bottom and allowed to sink into and grab the sediment, after which the bucket closes and the sediment is lifted up through the water and swung from the extraction location to the adjacent material transport barge where it is opened and releases the dredged material. The dredged material placed on the material transport barge is transported to a transload facility (that does not need to be adjacent to SIB Project Area). The water that is excavated with the dredge material is typically pumped to a connecting water containment barge and treated prior to release to the surrounding water body or other systems (e.g., sanitary sewer systems). Water treatment is addressed in Section 35 59 15 - Temporary Contact Water Treatment.

Mechanical dredgers may use a variety of bucket sizes, making them an effective method for large debris removal. While mechanical dredging has a lower production rate than hydraulic dredging, it causes minimal interference with navigation. In addition, mechanical dredgers have flexibility to conduct work in the upland area (dry excavation). The mechanically removed sediment contains a significantly lower volume of water requiring treatment and disposal.

In summary, mechanical dredging is recommended as the most suitable method for SIB Project Area. While hydraulic dredging remains a possible option depending on the future availability of upland properties and RA Contractor capabilities, hydraulic dredging is not currently recommended at the SIB Project Area due to the following conditions:

- Hydraulic dredging equipment would potentially require the removal of smaller debris (greater than 6 inches) prior to dredging so as to not clog the pipeline, and may face challenges from unidentified buried debris;

- Hydraulic dredging requires the use of slurry pipelines, which would continuously impact waterway users; and
- Significant amounts of slurry would be produced via hydraulic dredging and require dewatering (80 to 90% of the slurry is water), however no space within the SIB Project Area available for dewatering prior to transport and disposal has been identified. Mechanical dredging is anticipated to contain approximately 45% free water based on a bucket fill factor of 0.55 assumed in the mechanical dredging production rate analysis.

4.2. EQUIPMENT RECOMMENDATIONS

As discussed in Section 4.1, mechanical dredging is the recommended dredging methodology. Therefore, this section will discuss the specifics of equipment selection for mechanical dredging. It is of note that the final selection of equipment will be determined by the RA Contractor, based on the requirements of the technical specifications and other factors.

Equipment selection is based on many factors including RA Contractor experience and equipment availability. Additional factors include, but are not limited to, equipment compatibility with project site conditions, mode of transport, transload, and disposal routes. Efficiency of equipment for site conditions including debris, water depth, surface slope, sediment type, applicable performance standards, and presence of structures.

Mechanical dredges are classified into two primary systems, an articulated fixed arm system and a wire supported system. A fixed arm system uses an excavator or backhoe to remove sediment, while a wire supported system is attached to a crane. Mechanical dredgers are further described by the type of bucket used. Wire-supported buckets include a conventional clamshell bucket and enclosed bucket, while an articulated bucket is a fixed arm system (USACE, 2008).

A conventional clamshell bucket is a wire supported system and typically is crane mounted on a barge with buckets that may vary in size from less than 1 to 50 cubic yards (CY). The clamshell bucket is an open system that has teeth that are useful in removing hard sediment surfaces and debris. Due to the open nature, a clamshell bucket releases some sediment during removal but works well for debris removal. An environmental bucket or a closed bucket is a sealed (non-open system) without teeth using rubber gaskets and tongue-in-groove joints to seal it closed. The operation is the same as a conventional clamshell bucket, but its closed nature reduces sediment loss while making it less effective for debris removal (USACE, 2008).

An articulated arm bucket may be a clamshell or environmental bucket and is primarily used on land but may be operated from a barge. However, the bucket size does decrease as the length of the arm needed to dredge or excavate increases. Because of the fixed arm system, the articulated arm bucket is beneficial in areas with steeper slopes.

SIB has unconsolidated sediments that are laden with surface debris and unknown subsurface debris quantities or locations. In addition, there are areas of the dredge prism that have steeper slopes. Keeping the site conditions in mind, the use of a conventional clamshell bucket would be best employed during large debris removal or dredge activities in an identified potential concentrated debris field. An environmental bucket may be best applicable for the main dredging

operation where large debris has been removed, and an articulated fixed-arm bucket would best support dredging on steep slopes and for upland excavation.

4.3. WATER DEPTHS TO ACCOMMODATE CONSTRUCTION EQUIPMENT

This section outlines the limitations of the mechanical dredge equipment discussed in Section 4.2. Determination of appropriate dredge equipment requires an evaluation of the equipment's operational limitations, including water depth.

The ability of equipment to reach designated dredging areas is dependent on the draft of the vessel and local water depth, which varies seasonally. A typical material barge used to store, and transport dredged sediment is a 12 to15 ft side shell barge. The barge will likely have a 3 to 4 ft draft when empty, and approximately a 13-ft draft when fully loaded. A barge used to house the dredger will likely have a draft of approximately 4 to 8 ft.

While a cable crane and shell bucket will have the ability to reach farther inshore, the barges required for the equipment and weight of material are expected to draw more water, likely limiting the use of equipment to depths of approximately 10 ft for the dredge-mounted barge and 15-20 ft depth for a loaded material barge. An excavator mounted on a barge may have a shorter reach, but the barge should be lighter and have a smaller draft permitting the equipment to dredge in shallower areas. The anticipated required water depth to accommodate equipment was applied to the site access constraints assessment in Section 4.4. The RA contractor's knowledge of their equipment will guide the selection of the most applicable combination of equipment for the shallower areas.

4.4. SITE ACCESS CONSTRAINTS

An analysis was conducted to evaluate potential dredge plant site access constraints in the SIB Project Area. While the equipment used for the RA will be determined by the RA Contractor, the assessment conducted for a dredge plant applicable to the project objectives has been applied within the SIB Project Area. The evaluated equipment consisted of the following components:

- 210 ft by 62 ft - 2,500-ton material transport barge;
- 1,500-ton material transport barge;
- 123 ft by 62 ft by 12 ft water management barge;
- 142 ft by 58 ft by 12 ft dredging barge with minimum draft 6 ft (MER, 2024);
- Tug for moving barges; and
- Turbidity control measures (e.g., silt curtains). Turbidity control is described in the Drawings (Sheet DR101, Volume III, Appendix V) and Specification Section 01 35 43 (Environmental Protection Procedures).

The assessment applied the anticipated depth limitation for dredging equipment, dredge mounted barge dimension, and an average dredge arm radius of 100 ft to determine maximum reach. The material barge was placed adjacent to the dredge mounted barge, but its position was shifted to maximize dredger reach.

Based on the applied factors, several locations within the SIB Project Area were identified with access constraints. Areas behind the following structures are outside of the evaluated dredger arm reach radius:

- USCG Floating Dock
- U.S. Navy Pier
- MC Pier
- Berth 311

Dredging and excavation required in these areas will require alternate equipment and methodologies. In addition to the areas listed above, the far southeastern corner of SIB Project Area adjacent to the Wind Tunnel property, may have equipment depth requirement limitations. These potential limitations will depend on RA Contractor equipment and river conditions, and will therefore need to be evaluated by the RA Contractor. Access constraints will decrease the daily dredge production rate. The identified constraint areas within the SIB Project Area may require an amended dredging and/or capping approach from the RA Contractor. A feasible methodology may be for the dredger to place a smaller excavator with a sediment holding box on a flexi-float to dredge the sediment area not reachable by the dredge arm. Once the dredging is complete, the equipment would be removed by the dredger. The dredged material would then be relocated to the material transport barge.

4.5. DEBRIS AND DEBRIS REMOVAL

Large debris, which is defined as debris greater than 6 ft in any dimension, shall be removed prior to the start of dredging activities. It is estimated that SIB contains more than 650 pieces of large debris. Debris may be removed prior to dredging or concurrently, as deemed more appropriate by the RA Contractor for the most efficient means and methods. Debris removal is required to establish appropriate pre-capping surfaces to allow a continuous chemical isolation layer, and prevent differential settlement post-capping. Debris removal methodology will depend on RA Contractor selected means and methods. The initial debris size criterion governing pre-dredging removal will also be determined by the RA Contractor, since it depends on dredging bucket sizes used in different areas of SIB (e.g., open water or around structures). The quantity and types of debris were summarized in the BODR (HGL, 2024b). Although most of the debris is relatively small, some larger debris such as a sunken structure at Berth 308, several sunken small vessels, and larger timber piles/logs must be removed. Subsurface debris types and quantities are unknown but may be similar to surface debris. Removal and disposal of debris is discussed in the Pre-Final 90% RD Transportation and Off-Site Disposal Plan (Volume II, Appendix O).

4.6. SEDIMENT CHARACTERISTICS

The sediments in SIB are likely readily dredged and managed, based on extensive geotechnical investigations described in the PDI ER (HGL, 2024a). Sediment characteristics, geotechnical properties, slope stability under static and seismic conditions, and anticipated settlement post-capping are described in the BODR (HGL, 2024b) and the Geotechnical Design Technical Memorandum (Volume I, Appendix I).

4.7. NON-AQUEOUS PHASE LIQUID CONSIDERATIONS

The RD anticipates that non-aqueous phase liquid (NAPL) will be observed at the river surface during dredging. The process of cutting and drawing material through the water column can result in the release of NAPL entrained within the sediment pore space to the water column, where NAPL less dense than water will float to the surface. However, extensive sampling of SIB has provided relatively few locations where visible NAPL is present in the sediment; only 17 observations of NAPL were noted in more than 1,200 samples collected. Therefore, the areas where NAPL may be observed during dredging are relatively limited. The Water Quality Monitoring Plan (Volume II, Attachment C of Appendix N) provides the required controls (including NAPL controls) to be put in place during dredging activities, as well as the notifications to be made by the RA Contractor when these impacts are encountered. Additionally, the water treatment system required for dredged material water treatment will include a separations step that includes a NAPL adsorbent, so the NAPL releases during the RA will be well controlled. The dredge prisms designed for the SIB Project Area are intended to generally avoid a leave surface containing NAPL-impacted sediments; sample intervals with identified NAPL impacts will either be removed during dredging or remain under feet of sediment that do not contain entrained NAPL, based on the extensive sampling completed for the Project Area. However, as stated in NAPL Tech Memo (Volume I, Appendix B), for two core locations (E24 and E33) with observed NAPL within sample cores that intersect dredge leave surface, 3 inches of organoclay-containing granules will be placed within a 50-ft radius centered on these two locations after dredging and prior to capping to address the potential for NAPL at the post-dredged surface. If any other mobile NAPL is encountered, a 3-inch cap with a small mass of organoclay (2 percent by weight) will be placed post dredging and prior to capping.

Monitoring of the SIB surface water over time after dredging is the primary method of determining the need for the NAPL contingency cap. Observations of surface sheens will be continuously logged during the dredging work. The RA contractor will provide the observation records, including locations mapped of observed sheens. If multiple instances (multiple subsequent days) of discreet NAPL sheens are observed within a previously dredged area, the contractor will mobilize an aerial monitoring contractor (i.e. unmanned aerial vehicle [UAV] imaging) to document the precise locations of the NAPL source and the information will be used to estimate the aerial extent and mass of organoclay absorbent to be used for the contingency capping.

4.8. PRODUCTION RATES

Dredging production rates will vary around the site, primarily based on equipment type and efficiency of sediment removal due to access constraints (e.g., dredging under structures). Production rates may also be affected by sediment and/or water processing/treatment rates, transload rates, and acceptance rates at the disposal facility. Production rate calculations incorporate bucket size, fill factor, cycle time, dredging time (workday duration), and Effective Working Time (EWT) as shown below in Equations 1 and 2 (Webb et al., 2015):

$$Production_{(CY/hr)} = Bucket\ Size\ (CY) \times FillFactor \times \frac{3600\ s}{Cycle\ Time\ (s)} \quad (1)$$

$$Production_{(CY/day)} = Production_{(CY/hr)} \times (\#\ of\ hours\ worked/day) \times \%EWT \qquad (2)$$

Production rate estimates were developed for three types of areas within the SIB Project Area: open water, shallow areas/slopes, and under/around structures. Generally, these production rate scenarios represent different levels of operational difficulty and efficiency, which are largely caused by access constraints. Input parameters for Equations (1) and (2) were chosen based on a range of typical values observed in environmental dredging projects (Webb et al., 2015) and are summarized in Table 4-1.

Dredging in open water areas (low difficulty) was assumed to utilize a larger bucket size and have a lower cycle time. Dredging in shallow areas/slopes (medium difficulty) was assumed to require a moderate or small bucket size (depending on reach distance) and an average cycle time. Dredging under/around structures (high difficulty) was assumed to require a small or medium bucket size and have a higher cycle time.

For all dredging operations, it was assumed that a daily shift would be 12 hours with an EWT of 50% (i.e. 50% of the shift would be spent productively on dredging). A fill factor of 0.55 was assumed for all dredging operations. The resulting production rate values align with productivity data from published dredging studies (Webb et al., 2015). Table 4-1 summarizes the dredging production rate calculation inputs and results. These production rates were used in the development of the 90% RA Schedule (see Figure 3-1 of Volume I, Design Criteria Report). Approximate dredging volumes are also shown in Table 4-1. The approximate volume of dredging for steep slopes and around structures was lumped into a single volume here for simplicity, since the area of influence of structures (zone around a structure in which the structure effects efficiency) varies in size for each facility.

The production rates summarized in Table 4-1 are reasonably conservative and reflect additional care associated with remedial dredging in PHSS. For reference, recent maintenance dredging activities in SIB reported production rates upwards of 2,500 to 3,000 CY per day in open water. However, it should be noted that those maintenance dredging activities are not directly comparable to the remedial dredging due to differing requirements for equipment, procedures, environmental controls, materials handling and disposal.

4.9. DREDGE RETURN WATER MANAGEMENT

Water that contacts sediment on barges (dredge return water) will be removed during dredging for treatment. Water treatment is addressed in Specification Section 35 59 15 (Temporary Contact Water Treatment). The Water Quality Monitoring Plan (Volume II, Attachment C of Appendix N) further discusses treatment, monitoring, and discharge of dredge return water.

GEOTECHNICAL DESIGN TECHNICAL MEMORANDUM

This page was intentionally left blank.

GEOTECHNICAL DESIGN TECHNICAL MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
SWAN ISLAND BASIN PROJECT AREA, CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

This Geotechnical Design Technical Memorandum (GDTM) presents a summary of geotechnical design efforts for the Remedial Design (RD). The RD is conducted for the Swan Island Basin (SIB) Project Area within the Portland Harbor Superfund Site (PHSS) in Portland, Multnomah County, Oregon. The HydroGeoLogic, Inc. (HGL) team performed the work on behalf of the SIB RD Group based on the requirements of the PHSS Record of Decision (ROD) (EPA, 2017a) and the Administrative Settlement Agreement and Order on Consent (EPA, 2021a). The data used in the geotechnical analyses were collected in accordance with the final Pre-Design Investigation (PDI) Work Plan, which the U.S. Environmental Protection Agency (EPA) approved in May 2022 (HGL, 2022), and were reported in the PDI Evaluation Report (ER) (HGL, 2024), which EPA approved in January 2025.

This GDTM refines the geological and seismic ground model presented in the Draft 50% RD, summarizes and outlines the geotechnical analysis performed, and provides commentary regarding the geotechnical analysis and reporting that will be presented in the RD submittal. The geotechnical analyses presented herein support justification or elimination of proposed remedial technologies, and ultimately inform design and construction of the selected remedy. The geotechnical analysis elements presented herein include:

- Subsurface profiles and cross-sections that illustrate soil stratigraphy and include relevant geotechnical design parameters at key locations throughout the project area;
- Bearing resistance evaluation of cap foundation materials;
- Settlement analysis of both cap and cap foundation materials (underlying sediments).
- Seismic design parameters for a Contingency Level Earthquake (CLE), and other seismic hazard levels required for RD;
- Slope stability analysis, static and seismic (pseudo-static), of caps placed on slopes, proposed dredge cuts, and riverbank slopes;
- Seismic hazard analysis, including evaluation of liquefaction triggering, liquefaction induced settlement, and lateral spreading potential; and
- Lateral earth pressures for static and seismic loading conditions.

Section 1.0 summarizes the existing information and defines the geotechnical design areas and reaches. Section 2.0 describes the sub-surface conditions, including project specific engineering soil units. Section 3.0 presents the geotechnical and seismic design parameters for use in design. Section 4.0 summarizes the geotechnical design considerations and analyses, including the evaluation of seismic hazards, sediment cap design, riverbank slope design, and design of retaining

walls. Section 5.0 summarizes construction and monitoring considerations during construction, post construction and after seismic hazard events.

1.0 EXISTING SITE INFORMATION AND GEOTECHNICAL DESIGN AREAS

The following section presents a summary of the existing site information utilized for Pre-Final 90% RD and provides a detailed overview of the sub-areas within the larger SIB Project Area.

1.1 EXISTING GEOTECHNICAL DATA

Existing geotechnical data and information utilized in this technical memorandum are summarized within the Geotechnical Data Report (Appendix F of the PDI ER; HGL, 2024). Section 2.3 of the Geotechnical Data Report (HGL, 2024) presents a detailed summary of publicly available information and existing geotechnical data sources identified in proximity to the SIB Project Area. Information included in the following sections supplements the project-specific data and is utilized in the development of sub-surface profile across the SIB Project Area. The PDI geotechnical investigation comprised:

- 30 exploratory borings, 15 in-water borings, and 15 upland borings;
- 16 cone penetration tests (CPTs), which included pore pressure dissipation and seismic testing, 13 in-water CPTs, and 3 upland CPTs);
- Down-hole geophysical testing, including the in-situ measurement of small strain stress wave velocity (P and S waves) at 4 boring locations; and
- Geotechnical laboratory testing.

Figure 1-1 presents the geotechnical investigation locations undertaken as part of the PDI (HGL, 2024).

1.2 GEOLOGIC AND SEISMIC SETTING

A summary of the geologic and seismic setting as detailed in the PDI ER (HGL, 2024) is provided in the following subsections.

1.2.1 Regional and Site Geology

Regionally, the shallow geology is defined by the glacial outburst floods that scoured the underlying Troutdale Formation, depositing flood sediment. These Missoula Flood deposits are typically well-bedded white or tan sand and silt, with each layer representing individual flood events. These layers vary in thickness from a few inches to a few feet (Waitt, 1985; Benito and O'Connor, 2003; Waitt et al., 2009). The deposits from these floods underlie much of the region, contributing to the area's geological composition and landscape (Wells et al., 2020). In the SIB project area and the adjacent lowlands, sediment and soils above the flood deposits are characterized by unconsolidated, fine-grained alluvial deposits, resulting from sea level rise at the end of the last ice age (Beeson et al., 1991; Brown and Caldwell et al., 2008; Wells et al., 2020).

Artificial fill is considered to cover the entirety of the uplands. Material that covers Swan Island and its vicinity above water level is generally composed of sand, gravel, and rock placed for building foundations (Ma et al., 2012). Fill materials on Mocks Bottom are composed of materials dredged from the Willamette River and gravel and rock placed for construction.

1.2.2 Regional and Site Seismicity

The city of Portland is situated above the Cascadia Subduction Zone (CSZ) and is subject to ground shaking from the intra-slab and megathrust seismicity generated along the subduction zone and seismicity from crustal faults. Past earthquakes along the 600-mile CSZ fault have occurred at highly variable intervals, from decades to centuries, and have ranged widely in magnitude (OSSPAC, 2013). Studies of the geologic record suggest that a CSZ earthquake of magnitude 9.0 has a 7 to 11 percent chance of occurring within the next 50 years (Goldfinger et al., 2012).

Active local crustal faults should also be considered when evaluating potential earthquake impacts or ground motions at the SIB Project Area. The three northwest-trending faults are all mapped within 3 miles of the SIB Project Area.

1.2.3 Geologic and Seismic Hazards

Due to its geological setting and proximity to active faults, the SIB Project Area and uplands are likely to experience geologic and seismic hazards throughout the design life of the Remedial Action (RA). The geologic and seismic hazards of primary concern within the SIB Project Area are related to slope instability and deformation, under both static and seismic loading conditions. Due to the high susceptibility of soils within the SIB Project Area to liquefaction and lateral spreading, careful consideration was given to the design of riverbank slopes, as well as structural mitigation measures, and the incorporation of habitat elements into the RD. Additional detail regarding Project Area-specific geologic and seismic hazards, the geotechnical analyses performed to better understand them, and how the analysis results helped inform the RD are presented in the sections that follow, as well as in the attachments to this memorandum.

1.3 GEOTECHNICAL DESIGN AREAS AND SURFACE CONDITIONS

The SIB Project Area has been broken into three geotechnical design areas (Figure 1-2), and further divided into design reaches, based primarily on the condition and configuration of the riverbank slope, and property ownership (Figure 1-3). Defining both the design areas and reaches will allow specific design objectives and considerations to be addressed and communicated to the design team and project stakeholders. A brief description of each design reach and the surficial conditions is provided in the following sections.

1.3.1 Mocks Bottom – U.S. Coast Guard

The U.S. Coast Guard (USCG) design reach extends, approximately, between station 47+00 and 53+00. The slope runs in a westerly direction in the most northern corner of SIB. The crest of the riverbank varies between elevation 33- and 35-ft North American Vertical Datum of 1988 (NAVD88). The riverbank characterization conducted during the PDI (HGL, 2024) noted that above the ordinary high water (OHW) (20.1 ft NAVD88), the slope is densely vegetated, with an

exposed beach to the west of the pier structure. The slope sits at an approximate 23 degree (°) to 30° angle above the approximate mean low water (MLW) (7.28 ft NAVD88) and 15° to 25° below. Two operating structures are located within the USCG design area: a pier structure and a floating dock. Two buildings are located near the crest of the slope, with an operating yard and access to the pier along the remainder of the slope.

1.3.2 Mocks Bottom – U.S. Navy

The Navy design reach extends approximately between station 41+00 and 47+00. The slope adjacent to the USCG parcel runs in a north westerly direction. The crest of the riverbank varies between 34- and 36- ft NAVD88. The riverbank characterization conducted during the PDI (HGL, 2024) noted that the riverbank was armored and densely vegetated. The slope sits at an approximate 20° to 25° angle, assumed to extend to the toe of the slope. A single operating pier is located within the design area. Buildings are set back from the crest of the slope; however, large storage containers are placed within 20 ft of the top of slope.

1.3.3 Mocks Bottom – The Marine Consortium, Inc.

The Marine Consortium, Inc. (MC) design reach extends approximately between station 32+00 and 41+00. The slope runs in a north westerly direction. The crest of the riverbank varies between 36- and 38- ft NAVD88. The riverbank characterization conducted during the PDI (HGL, 2024) noted the riverbank to be heavily armored. The slope sits at an approximate 25° to 30° angle above the MLW and 10° to 25° below. Access to a single operating pier is located within the design area. Parking and storage containers are located at the crest of the slope.

1.3.4 Mocks Bottom – Port of Portland Dredge Base

The Port of Portland Dredge Base design area extends approximately between station 22+00 and 32+00. The slope runs in a north westerly direction. The crest of the riverbank varies between 34- and 36- ft NAVD88. The riverbank characterization conducted during the PDI (HGL, 2024) noted armoring to be present below the OHW. A sand and gravel beach is present below the MLW. The slope sits at an approximate 20° to 25° angle above the MLW and 10° to 20° below. In addition to a single pier structure leading to the dredge barges, a boat ramp is located at approximate station 25+00. The crest of the slope is mostly vegetated, apart from the pier access point which is used for storage.

1.3.5 Mocks Bottom – ATC Leasing

The ATC Leasing design area extends approximately between station 17+00 and 22+00. The slope runs in a north westerly direction. The crest of the riverbank varies between 32- and 34- ft NAVD88. Above MLW the slope is benched with an upper slope set back from the water sitting at an approximate 30° angle. Below this the slope gradually falls into the water at an approximate 10° angle. The upper slope is mostly vegetated with exposed sandy material in the lower shallow slopes.

1.3.6 Mocks Bottom –Berth 311

The Berth 311 design reach extends approximately between station 8+00 and 17+00. The slope runs in a north westerly direction. The crest of the riverbank varies between 36- and 38- ft NAVD88. Above MLW the slope is benched with heavy vegetation. The upper slope sits at an approximate 30° to 35° angle above the MLW and 10° to 20° below. A large single pier supported on timber piles with two access points is located within the design area. The crest of the slope is vegetated and parking associated with the operator is located more than approximately 10 ft back from the crest of the slope.

The remainder of the Swan Island Dock Company reach extends approximately between the head of the basin and station 8+00. The slope runs in a north westerly direction. The crest of the riverbank varies between 32- and 34- ft NAVD88. Above MLW the slope is benched with an upper slope set back from the water sitting at an approximate 30° to 45° angle. Below this the slope gradually falls into the water at an approximate 10° to 15° angle. The upper slope is mostly vegetated with exposed sandy material in the lower shallow slopes. Storage areas are located close (within 10 ft) to the crest of the slope.

1.3.7 Head of the Basin

This design reach sits at the head of the basin and encompasses the public boat ramp. The riverbank characterization conducted during the PDI (HGL, 2024) noted riprap present adjacent to the public boat ramp. The remainder of the design area comprises mostly sand at surface. The crest of the riverbank varies between 34- and 36- ft NAVD88. The slope is noted to be relatively shallow varying between 10° to 20° angle with localized steeper sections.

1.3.8 Swan Island – Freightliner Wind Tunnel

The design reach adjacent to the head of the basin includes the wind tunnel structure. The crest of the riverbank varies between 34- and 36- ft NAVD88. The slope sits at an approximate 20° to 30° angle above MLW and 10° to 20° below. A small retaining wall is present directly below the wind tunnel. The riverbank characterization conducted during the PDI (HGL, 2024) noted riprap to be present below the OHW.

1.3.9 Swan Island – Berths 306, 307, and 308

This design area extends between station 6+00 and 21+00 on Swan Island. The riverbank encompasses three berth structures and associated timber dolphins. The riverbank characterization conducted during the PDI (HGL, 2024) noted rock/riprap armoring present in areas below OHW. The remainder of the slope above OHW is vegetated. Relic timber piles are present along the slope, approximately at the waterline. Signs of slope failure are noted near Berths 306 and 307 (HGL, 2024). The crest of the riverbank varies between 34 and 36 ft NAVD88. The slope sits at an approximate 20° to 30° angle above MLW and 10° to 20° below.

1.3.10 Swan Island –Lagoon Wharf

This design area spans from Berth 305 to Pier A, covering approximately stations 21+00 to 41+00. The Lagoon Wharf design area includes Berths 302, 303, 304, and 305. The crest of the riverbank varies between elevations of 35- and 37- ft NAVD88. A retaining wall, ranging from 7 to 20 ft in height, sits above MLW, with slope angles between 15° and 30°, featuring localized steeper sections. Below MLW, the slope angles range from 15° to 70°. The Lagoon Wharf structure, supported by timber piles, extends to the retaining wall on the southwest end of the design area. The wharf structure is approximately 52 ft wide on the northwest end (stations 41+00 to 27+00) and about 77 ft wide on the southeast end (stations 27+00 to 21+00).

1.3.11 Swan Island –Pier A and Quay Wall

This design area includes Pier A (Berth 301), located approximately between stations 41+00 and 61+00, and a quay wall situated between stations 61+00 and 67+00. Pier A has a top elevation of approximately 35 ft NAVD88. The pier structure is approximately 930 ft long, with its width gradually increases from 47 ft on the west end to 65 ft on the east end. Built in the 1940s, the pier contains 20 diaphragm cells, 3 circular cells, and 1 closure pile cell (Roth and Ramage, 1975). Originally, Pier A was designed to consist of 28 diaphragm cells. However, eight diaphragm cells failed during construction due to base failures caused by excessive hydrostatic head and impaired drainage during the hydraulic placement of cell fill materials. These eight diaphragm cells were replaced with three circular cells and one closure steel sheet pile cell. The quay wall is an earth-retaining structure consisting of nine circular steel sheet pile cells with connecting arcs, one steel sheet pile closure cell, one diaphragm wall, and a section of anchored steel sheet pile bulkhead (Roth and Ramage, 1975).

1.3.12 Swan Island –Floating Dock and Demo Pier

This design reach is situated at the head of Swan Island, extending from the end of the Quay Wall to the southern extent of the Demo Pier. It includes a riverbank that runs southeast for approximately 430 ft and then south for about 510 ft. The riverbank features an engineered bank with riprap below the OHW and a vegetated bank above OHW in the dry dock basin. The slope angle varies between 28° and 38°. The crest of the riverbank varies approximately between 35- and 37- ft NAVD88.

2.0 SUBSURFACE CONDITIONS

The section provides information on the sequence of strata encountered during the geotechnical investigations to date, and on the anticipated hydrogeological conditions at the Project Area based on the data available.

2.1 ENGINEERING SOIL UNITS

Four geologic unit layers were identified in the SIB Project Area geotechnical investigation during the PDI (HGL, 2024). These materials recorded on-site have been split into several engineering soil units for use in geotechnical analysis in the Pre-Final 90% RD. Interpretation of the engineering soil units identified in the PDI is described in the following sections.

2.1.1 Artificial Fill

Non-native fill deposits were encountered at the ground surface in all on-land borings. The material is generally described as loose to medium dense, poorly graded sand with clay and/or silt. The sand is described as fine to medium with occasional traces of fine gravel. Laboratory classification tests indicate the material to be predominantly coarse with an average particle distribution of 9 percent gravel, 72 percent sand, and 18 percent fines. Standard penetration tests (SPT) N_{60} values recorded values between 4 and 53, with an average of 22, which indicates the variable nature of the material. Fill was not recorded in any of the in-water investigations.

2.1.2 Recent Basin Sediments

Material described as recent basin sediments was recorded in the Swan Island Basin. The material was noted to vary in description between the north and south of the basin. In-water positions adjacent to Mocks Bottom (north) described the recent basin sediment as poorly graded silty sand and soft sandy silt. Factions of both silt and clay were noted within the sand layers. Laboratory classification tests indicate the material in the north of the basin to be predominantly coarse with an average particle distribution of 89 percent sand and 11 percent fines. SPT N_{60} values recorded values between 2 and 14, with an average of 8, indicating the relatively loose nature of the material.

In-water closer positions undertaken in the center of SIB and adjacent to Swan Island (south) described the recent basin sediment as very soft to soft elastic silt. Laboratory classification tests indicate the material in the center and south of the basin to be predominantly fine with average particle distribution of 41 percent sand and 59 percent fines. Atterberg limits recorded the material to be predominantly silts of medium to high plasticity.

2.1.3 Alluvium (Holocene): Sand

Coarse alluvial deposits were recorded directly below the artificial fill layer in the majority of positions across the Project Area. The deposits were described as loose to medium dense poorly graded silty or clayey sand. Laboratory classification tests support the geological descriptions with average particle distribution of 7 percent gravel, 76 percent sand and 17 percent fines. SPT N_{60} values recorded values between 7 and 49, with an average of 24, indicating the layer to be loose to medium dense.

2.1.4 Alluvium (Holocene): Clay

A consistent fine layer was recorded directly below the alluvial sand within Mocks Bottom. This material was described as interbedded layers of lean and fat clay of mixed plasticity. Laboratory classification tests indicate the material to be predominantly fine with average particle distribution of 9 percent gravel, 29 percent sand and 62 percent fines. Atterberg limits testing recorded the material to be predominantly medium to high plasticity clays.

2.1.5 Missoula Flood Deposits (Pleistocene): Silt

Two distinct layers of fine Missoula Flood Deposits were recorded within SIB. The first layer sits directly below the alluvial deposits and above the coarse Missoula Flood Deposits. A second fine

layer was noted below the coarse layers in localized areas. Both layers are typically described as sandy silt with layers of elastic silt. Laboratory classification tests indicate the material to be predominantly fine with average particle distribution of 35 percent sand and 65 percent fines. Atterberg limits testing indicates the material to behave as a medium silt.

2.1.6 Missoula Flood Deposits (Pleistocene): Sand

Coarse Missoula Flood Deposits were recorded directly below the fine clay layer, typically described as layers of loose to medium dense poorly graded sand with silt and silty sand. Occasional traces of fine gravel were noted. Laboratory classification tests support the geological descriptions with average particle distribution of 2 percent gravel, 82 percent sand and 16 percent fines. SPT N_{60} values recorded values between 1 and 65, with an average of 25. The results indicate the material to be predominantly medium dense with a slight increase in relative density with depth.

2.1.7 Troutdale Conglomerate

Troutdale conglomerate is the layer below the Missoula Flood Deposits. This stratum was not encountered within the ground investigations undertaken. The geological mapping (Madin, 2024) describes the material as friable to moderately strong conglomerates with minor interbeds of sandstone, siltstone, and claystone.

2.2 GROUNDWATER CONDITIONS

Based on the geotechnical investigation during the PDI (HGL, 2024) shallow groundwater is controlled by the water level within SIB. Geotechnical drilling and pore pressure dissipation tests from seismic cone penetration testing (sCPT) soundings indicate that groundwater elevations within the SIB Project Area range from approximately 6- to 27- ft NAVD88. This variation in groundwater levels is influenced by several factors, including topography, soil permeability, and seasonal changes.

2.3 VARIATIONS IN SUBSURFACE AND GROUNDWATER CONDITIONS

The subsurface stratigraphy generally follows a consistent sequence, but there are notable variations between Swan Island, the head of the basin, and Mocks Bottom. In the Swan Island on-land positions, fine alluvial deposits were not recorded. At the head of the basin, there is a significant layer of recent basin deposits both in-water and on-land, likely due to the infilling of the main channel of the Willamette River to create SIB. In contrast, fine alluvial deposits are consistently observed in the subsurface explorations at Mocks Bottom. These fine materials typically underlie coarse materials of the same geology. However, it is important to note that the fine alluvial materials and the underlying fine Missoula deposits are similar in field description, making it challenging to delineate the layers. This variation has been considered in the subsurface profiles described in the following section.

Localized zones of perched water are expected, particularly during and following the rainy season. These perched water zones occur due to variations in soil permeability and the presence of less permeable layers that trap water above the main groundwater table. Additionally, soil moisture

content will vary significantly, influenced by rainfall patterns and surface water infiltration. The irrigation of landscaped areas and potential leaks from water infrastructure can further affect groundwater levels and soil moisture content. These activities can create localized areas of higher moisture content and potentially contribute to perched water zones. It is important to consider these factors during the planning and construction phases to mitigate any adverse effects on the project.

Post-flooding, the drawdown of floodwaters could create an imbalance in pore pressures within a slope. The river level may recede faster than the soil drains, leading to excess pore pressure and instability of the existing slopes.

The groundwater conditions are heavily influenced by the water level within SIB. Ground investigations in the northern section of Mocks Bottom recorded groundwater levels between approximately 11 ft and 17 ft NAV88, corresponding to levels between OHW and MLW. The critical groundwater level is dependent on the design scenario and will be assessed on a case-by-case basis.

2.4 SUBSURFACE PROFILES

The following section presents the generalized subsurface profile considered for each of the design areas. The subsurface profiles have been developed across the SIB Project Area and are presented on Figures 2-1a to Figure 2-1r. It should be noted that the stratigraphy presented is generalized for each specific section; localized variation in the stratigraphy may exist and has been considered in the analysis.

2.4.1 Mocks Bottom – U.S. Coast Guard

The upland ground model for the USCG comprises artificial fill from ground level to an approximate depth of 23 ft. The base of the fill layer is considered to be level for design. The fill is underlain by a 10 ft layer of coarse alluvium and sequentially 45 ft of fine alluvium. The alluvium is assumed to thin out as it progresses to the toe of the slope. Missoula sand deposits are then present to depth (greater than 86.5 ft). The base of this layer was not determined.

The in-water ground model comprises approximately 5 ft of recent basin sediments, predominantly fine. This is underlain by 15 ft of alluvial sand. Missoula silt deposits are then present to depth (greater than 80 ft). The base of this layer was not determined.

2.4.2 Mocks Bottom – U.S. Navy

The upland ground model for the Navy comprises artificial fill from ground level to an approximate depth of 25 ft. This is underlain by a 15 ft layer of coarse alluvium and sequentially 10 ft of fine alluvium. The fine alluvium is assumed to thin out as it progresses to the toe of the slope. Missoula silt deposits are then present to depth (greater than 86.5 ft). The base of this layer was not determined.

In-water ground model is considered to be variable across the design area due to past dredging activity and the deposition of recent basin sediments. For the purposes of design, it is assumed a 12 ft layer of coarse recent basin sediments overlies 10 ft of Missoula silt deposits and sequentially Missoula Sand to depth (greater than 61.5 ft).

2.4.3 Mocks Bottom – The Marine Consortium, Inc.

The upland ground model for MC design reach comprises artificial fill from ground level to an approximate depth between of 18 and 23 ft. This is underlain by a 10 to 15 ft layer of coarse alluvium and sequentially 10 to 48 ft of fine alluvium. Both the coarse alluvium and fine alluvium is assumed to thin out as it progressed to the toe of the slope. Missoula silt deposits are then present to a max 78 ft. The base of the Missoula sand deposits was not determined (greater than 98 ft).

In-water ground model is considered to be variable across the design area due to past dredging activity and the deposition of recent basin sediments. A thin layer of coarse alluvium is assumed to be present at surface on the slope (5.5 ft). At the toe of the slope the alluvial deposits are not present and have most likely been removed by dredging. Surface material comprise basin sediments approximately 10 ft in depth, underlain by approximately 14.5 ft of Missoula silt deposits. Missoula sand deposits underlie this layer to a depth greater than 62.5 ft.

2.4.4 Mocks Bottom – Port of Portland Dredge Base

The upland ground model for the Dredge Base comprises artificial fill from ground level to an approximate depth of 28 ft. This is underlain by 20 ft of fine alluvium. The alluvium is assumed to thin out as it progressed to the toe of the slope. Missoula silt deposits are then present to a depth of 73 ft.

The in-water ground model is considered to be variable across the design area due to past dredging activity and the deposition of recent basin sediments. A thin layer (5.5 ft) is assumed to be present as you move towards the center of the basin. It is assumed in design to be present at the toe of the slope.

2.4.5 Mocks Bottom – ATC Leasing

The upland ground model for the ATC Leasing design reach comprises artificial fill from ground level to an approximate depth between of 12 and 21.5 ft. This is underlain by a 6.5 to 13 ft layer of coarse alluvium and sequentially 18 to 20 ft of fine alluvium. Missoula silt deposits are then present to a max 73 ft. The base of the Missoula sand deposits was not determined (greater than 121.5 ft).

The in-water ground model is considered to be variable across the design area due to past dredging activity and the deposition of recent basin sediments. A layer varying in depth (max recorded 16 ft depth) is assumed to be present as you move towards the center of the basin. It is assumed in design to be present at the toe of the slope.

2.4.6 Mocks Bottom –Berth 311

The upland ground model for the Berth 311 comprises artificial fill from ground level to an approximate depth of 12 to 15 ft. This is underlain by a 13-to-15-foot layer of coarse alluvium and sequentially 18 ft of fine alluvium. Missoula silt deposits are then present to a max 86 ft. The base of the Missoula sand deposits was not determined (greater than 121.5 ft).

The in-water ground model is considered to be variable across the design area due to past dredging activity and the deposition of recent basin sediments. A layer varying in depth (max recorded 16 ft depth) is assumed to be present as you move towards the center of the basin. It is assumed in design to be present at the toe of the slope.

2.4.7 Head of the Basin

The upland ground model for the head of the basin design area comprises artificial fill from ground level to an approximate depth of 33 ft. This is underlain by 35 ft of recent basin deposits. Missoula silt deposits are then present to a max 78 ft. The base of the Missoula sand deposits was not determined (greater than 120 ft).

The in-water ground model consists of recent basin deposits to a depth of 37 ft. This is underlain by Missoula Flood Deposits to a depth of 75 ft (base was not determined).

2.4.8 Swan Island – Freightliner Wind Tunnel

The upland ground model for Freightliner Wind Tunnel comprises artificial fill from ground level to an approximate depth of 24 ft. This is underlain by a 15-foot layer of coarse alluvium. Missoula silt deposits are then present to a maximum of depth of 69 ft and are underlain by Missoula sand deposits. The base of the Missoula sand deposits was not determined (greater than 86.5 ft).

The in-water ground model consists of recent basin deposits to a depth of 37 ft. This is underlain by Missoula Flood Deposits to a depth of 75 ft (base was not determined).

2.4.9 Swan Island – Berths 306, 307 and 308

The upland ground model for Berths 306, 307, and 308 comprises artificial fill from ground level to an approximate depth of 24 to 28 ft. This is underlain by a 15-to-20-ft layer of coarse alluvium. Missoula silt deposits are then present to a maximum depth of 69 ft and are underlain by Missoula sand deposits. The base of the Missoula sand deposits was recorded at 118 ft depth B-12. Below this a secondary Missoula silt deposit layer was recorded to a depth of 121.5 ft.

The in-water ground model consists of recent basin deposits to an approximate depth of 6 to 22 ft. This is underlain by Missoula silt deposits to an approximate depth between 12 and 35. Coarse Missoula Flood Deposits are recorded to a max depth of 75.5 ft (base was not determined).

2.4.10 Swan Island –Lagoon Wharf

The upland ground model comprises artificial fill from ground level to an approximate depth of 23 to 29 ft. This is underlain by approximately 20 to 30-ft layer of coarse alluvium. A silt layer is then present around 53 to 55 ft depth for approximately 30 to 35 ft. A Missoula sand deposit underlies the Missoula silt deposit layer with local thin layers of finer material. Then, based on in-water investigations and adjacent Berth 306 investigation data, the Missoula sand deposit layer is assumed to start at approximately 120 ft depth.

The in-water ground model consists of approximately 6-ft thick recent basin deposits at approximately -28 ft NAVD88. This is underlain by approximately 5 ft of coarse alluvium, approximately 10 ft of fine alluvium, and approximately 36 ft of coarse Missoula Flood Deposits, respectively. A fine-grained Missoula Flood deposit with unknown depth starts around -84 ft NAVD88.

2.4.11 Swan Island –Pier A and Quay Wall

The upland ground model comprises an artificial fill layer from ground level (35 ft NAVD88). Based on Swan Island Ship Repair Yard Quay Wall Structure Stability Evaluation Report (Roth and Ramage, 1975), the depth of the artificial fill is approximately 60 ft (at Pier A) and 60 to 70 ft (at Quay Wall). At Pier A, the artificial fill layer is underlain by a course alluvium layer with a thickness of approximately 14 ft. This is underlain by the cohesive Missoula flood deposit layer at approximately -34 to -38 ft NAVD88 with a thickness of approximately 11 to 16 ft. The cohesionless Missoula flood deposit layer starts at approximately -49 ft NAVD88 (the base was not determined).

Roth and Ramage (1975) highlighted that different methods were used during the placement of the artificial fill, namely (1) hydraulic method and (2) clamshell bucket and back dumping, and reported a method-dependent variability in the artificial fill characteristics. It was also stated that the fill material might have not been properly compacted and looser soil zones could be encountered.

The in-water ground model at the west of Quay Wall and south of Pier A consists of recent basin deposits to an approximate depth of 6 ft. This is underlain by the cohesionless Missoula flood deposit layer at approximately -50 ft NAVD88 (the base was not determined).

Similarly, the in-water ground model at the north of Pier A consists of recent basin deposits to an approximate depth of 7 to 8 ft at approximately -30 ft NAVD88. This is underlain by the cohesive Missoula flood deposit layer (approximately 11 ft), and then the cohesionless Missoula flood deposit layer, which starts at approximately -49 ft NAVD88, and its base was not determined.

2.4.12 Swan Island –Floating Dock and Demo Pier

The upland ground model surrounding the Floating Dock/East, West and Demo Pier comprises artificial fill from ground level to an approximate depth of 28.5 ft. This is underlain coarse alluvial deposits to a depth greater than 71.5 ft (base was not determined).

The in-water ground model consists of recent basin deposits to an approximate depth of 5 to 7 ft. This is underlain by coarse alluvial deposits to a maximum depth of 34.5 ft. Missoula flood deposits were recorded to a maximum depth of 57 ft (base was not determined).

3.0 GEOTECHNICAL AND SEISMIC DESIGN PARAMETERS

Geotechnical and seismic design parameters were developed based on the results of the SIB Project Area geotechnical investigation during the PDI (HGL, 2024), including the results of in situ and

laboratory testing, soil descriptions from borehole logs in the SIB Project Area, groundwater data, and published data and historical information from relevant sources.

3.1 GEOTECHNICAL DESIGN PARAMETERS

Geotechnical parameters for RD are detailed in Table 3-1, with the basis of interpretation provided in Attachment A. These parameters have been derived for the geotechnical design of riverbank stability, preliminary lateral pile analysis, and sediment cap design (bearing capacity and settlement). Additional geotechnical parameters, if required, will be included in subsequent sections. Attachment A includes a description of the derivation of the parameters discussed in the following sections.

3.1.1 Bulk Unit Weight

Bulk unit weight represents the weight of a material per unit volume, including the water content. It is required for calculating earth pressures, slope stability and bearing capacity in geotechnical design. Bulk unit weight varies with soil type, moisture content and compaction. Bulk unit weights have been estimated from initial bulk density from test results (Triaxial and direct shear tests), multiplied by g (acceleration due to gravity), these values were compared against parameters presented in published literature based on descriptions and in situ density measurements.

3.1.2 Drained Shear Strength

Drained shear strength parameters, including effective cohesion (c′) and the effective angle of internal friction (ϕ’), are essential for evaluating the long-term stability and behavior of soils. Effective cohesion represents the shear strength due to interparticle forces, while the effective angle of internal friction reflects the shear strength from particle friction. These values have been determined through laboratory tests including triaxial compression and direct shear tests under drained conditions. Drained shear strength has been correlated with SPT and CPT data collected during the field investigation. Empirical correlations are presented in Attachment A.

3.1.3 Undrained Shear Strength

Undrained shear strength (Su) is a key parameter for assessing the short-term stability of soils, particularly in fine soils. Undrained shear strength is independent of normal stress and has been determined through triaxial compression under undrained conditions. Undrained shear strength has been correlated with SPT and CPT. Empirical correlations are presented in Attachment A.

3.1.4 Consolidation Parameters

Consolidation parameters have been determined within SIB to predict the settlement of the material beneath the proposed cap. These parameters are particularly relevant for fine-grained materials. Since the cap will consist entirely of coarse-grained material, consolidation-related settlement of the cap is not anticipated.

The compression index (C'_c) and recompression index (C'_r) are parameters used to define the compressibility of soils. The compression index represents the slope of the virgin compression curve on a plot of void ratio versus the logarithm of effective stress, indicating how much a soil

will compress under a given load. The recompression index, on the other hand, represents the slope of the rebound-recompression curve, which is used for overconsolidated soils. This index describes the soil's behavior when it is unloaded and then reloaded.

Permeability values in addition to the compression indices have been used to determine the coefficient of consolidation for time-dependent settlement analysis. Derivation of consolidation parameters are discussed further in Attachment A.

3.1.5 Lateral Earth Pressure Parameters

Lateral earth pressure parameters are required for designing retaining structures. These parameters include the active earth pressure coefficient (K_a), passive earth pressure coefficient (K_p), and at-rest earth pressure coefficient (K_0). The active earth pressure occurs when a retaining wall moves away from the soil, reducing the lateral pressure exerted by the soil. Conversely, passive earth pressure develops when the wall moves towards the soil, increasing the lateral pressure. The at-rest earth pressure is the lateral pressure exerted by the soil when the wall does not move. At-rest earth pressure has been determined based on correlations with internal friction angle for normally consolidated material. Empirical correlations are presented in Attachment A.

3.2 SEISMIC DESIGN PARAMETERS

The SIB Project Area is located within an active seismic region with the CSZ as the hazard-controlling seismic source capable of generating large-magnitude earthquakes including megathrust interface events. Also, shallow crustal sources including the Portland Hills fault contributes to the seismic hazards at the Project Area, which are shown in Figure 2-5 of Geotechnical Data Report (Appendix F of PDI ER; HGL, 2024).

The design-level earthquakes considered include the CLE and the Design Earthquake (DE), consistent with EPA and U.S. Army Corps of Engineers guidance for critical infrastructure. The CLE is defined in the Remedial Design Guidelines and Considerations (RDGC; EPA, 2021b) while the DE is based on ASCE 61-14 and ASCE 7-22. CLE ground motions are based on a 10 percent probability of exceedance in 50 years (i.e., a return period of 475 years) and represent the appropriate seismic hazard level for the majority of the RD. DE ground motions are defined by two thirds of Risk-targeted Maximum Considered Earthquake (MCER) based on a 2 percent probability of exceedance in 50 years (i.e., a return period of 2,475 years) and should only be used when considering structures designed in accordance with ASCE 61-14. Seismic design parameters were developed based on two unique seismic hazard levels, a CLE as defined in the Remedial Design Guidelines and Considerations (RDGC) (EPA, 2021b), and a Design Earthquake (DE) based on ASCE 61-14 and ASCE 7-22. CLE ground motions are based on a 10 percent probability of exceedance in 50 years (i.e., a return period of 475 years) and represent the appropriate seismic hazard level for the majority of the RD. DE ground motions are based on a 2 percent probability of exceedance in 50 years (i.e., a return period of 2,475 years) and should only be used when considering structures designed in accordance with ASCE 61-14.

The 2018 U.S. Geological Survey (USGS) National Seismic Hazard Model (NSHM; Powers et al., 2021) was employed in the seismic hazard assessment. The coordinates used to represent the

SIB Project Area in the seismic hazard analysis, shown in the World Geodetic System 1984 (WGS84) coordinate system, are:

- Latitude – 45.56617 N
- Longitude – -122.71595 E

3.2.1 Seismic Site Class

Based on shear wave velocity (V_S) data collected during the PDI (HGL, 2024), the SIB Project Area has a time-averaged shear wave velocity in the upper 30 meters or 100 ft (V_{S30}) of 615 ft per second (ft/sec) or 188 meters per second (m/s). This V_{S30} value corresponds to Site Class DE, loose sand or medium stiff clay, based on Table 20.2-1 of ASCE 7-22. Accordingly, CLE and DE ground motions were estimated for Site Class DE (a V_{S30} of 185 m/s). The V_S data used for V_{S30} development include compressional (P) and shear (S) wave suspension logging and Seismic CPT (SCPT) data (HGL, 2024), presented in Figure 5-3 of Geotechnical Data Report (HGL, 2024). Geotechnical investigation locations where P-S suspension logging was performed, and where SCPT data was collected, are shown in Figure 1-1.

It should be noted that Section 20.2.1 of ASCE 7-22 dictates that if the site soil profile includes soils vulnerable to potential failure or collapse under seismic loading, such as liquefiable soils, the site should be classified as Site Class F, and a site response analysis is required. However, this applies only to structures that have fundamental periods of vibration greater than 0.5 sec.

Based on our current understanding of the RD, the estimated fundamental periods of vibration of the new structures and sliding masses are less than 0.5 seconds. If structures or sliding masses with estimated fundamental periods of vibration greater than 0.5 seconds are incorporated into the final design, the seismic site class determination should be reconsidered, and a site response analysis will likely be required.

3.2.2 Earthquake Ground Motions

CLE ground motion parameters were determined with the Uniform Hazard Response Spectrum (UHRS) associated with the 475-year return period from the 2018 USGS NSHM (Powers et al., 2021) using the USGS Earthquake Hazard Toolbox (USGS, 2024). DE ground motion parameters per Section 11.4.5 of ASCE 7-22 were obtained from the ASCE 7 Hazard Tool (ASCE, 2024).

The 5 percent damped design earthquake response spectra for CLE and DE are shown in Figure 3-2 and Figure 3-3, respectively.

3.2.3 Seismic Hazard Disaggregation

A disaggregation of the total seismic hazard per the 2018 USGS NSHM was performed using the USGS Earthquake Hazard Toolbox (USGS, 2024). The disaggregation was performed to identify the principal individual sources contributing to the total seismic hazard at the Project Area.

Disaggregation results for Peak Ground Acceleration (PGA) include modal values of earthquake magnitude (M_W) and source-to-site distance (R) associated with the source most contributing to the seismic hazard at the Project Area. The results for the return periods of 475 years and 2,475

years are presented in Figure 3-4. The hazard-controlling seismic source was determined as the CSZ (interface), with a governing Mw of approximately 9.1 and R of 76 km, and considered in the liquefaction triggering analysis.

4.0 GEOTECHNICAL DESIGN CONSIDERATIONS

The ROD (EPA, 2017) provides a framework for cleanup decisions based on contamination levels and areas needing remediation. The project team has set design goals using this framework and previous investigation results. Key geotechnical considerations include stability of riverbanks and underwater slopes, cap requirements, seismic impacts, and erosion risks. The following sections explains how these considerations have been addressed as part of the Pre-Final 90% RD.

4.1 LIQUEFACTION

Earthquake-induced soil liquefaction can be described as a significant loss of soil strength and stiffness caused by an increase in pore water pressure resulting from cyclic loading during shaking. Liquefaction is most prevalent in loose to medium dense, saturated, granular soils, but can also occur in non-plastic to low-plasticity finer grained soils.

The potential consequences of liquefaction include, but are not limited to, increased lateral earth pressures on retaining walls, liquefaction induced settlement, and lateral spreading or “flow failures” in slopes.

4.1.1 Liquefaction Triggering Evaluation

For layers that met the compositional criteria, liquefaction triggering (factor of safety) analyses was performed using CLiq, Version 3.5.22 (GeoLogismiki 2007) and the procedures proposed by Boulanger and Idriss (2014). The analyses utilized both SPT data, and CPT tip resistance data collected as part of the geotechnical investigation. The SPT-based assessment was performed to supplement the CPT-based analysis by filling spatial gaps between CPT locations, specifically when considering the lateral continuity of identified liquefiable layers. A groundwater elevation of 20 ft (NAVD88), which is consistent with the OHW elevation within the SIB Project Area, was considered during liquefaction triggering analysis.

Peak ground acceleration (PGA) at the ground surface and earthquake magnitude (MW) represent the seismic demand input parameters required for SPT and CPT-based liquefaction triggering evaluation. The PGA and MW for the CLE were considered in the liquefaction triggering analysis presented herein.

The Geotechnical Data Report (HGL, 2024) indicates the liquefaction susceptibility at the Project Area should be considered very high, which was in line with the overall results from the liquefaction triggering analyses for the CLE event. Based on our liquefaction triggering analyses, all SPT and CPT locations analyzed appeared to have potentially liquefiable soils at various depths and thicknesses.

Liquefaction triggering of low plasticity fine-grained soils was also assessed by the procedure per Bray and Sancio (2006) using the Atterberg limits and water contents data from laboratory tests. The used laboratory test data were from all the boreholes considered in the SPT-based simplified

procedure. The data showed most of these fine-grained soils were not susceptible to liquefaction Also, fine-grained soils encountered in the geotechnical borings typically have a plasticity index (PI) of about 7 or higher, indicating clay-like behavior/potentially cyclic softening material (Boulanger and Idriss, 2006).

Liquefaction analysis reports that summarize the input parameters and analysis results for each CPT and SPT location analyzed were generated in CLiq and are presented in Attachment B.

4.1.2 Ground Motions for Liquefaction Analysis

Peak ground acceleration (PGA) at the ground surface and earthquake M represent the seismic demand input parameters required for SPT and CPT based liquefaction triggering evaluation. The PGA and earthquake M considered in Final RD liquefaction triggering analysis were based on CLE and DE seismic events and the seismic hazard disaggregation data described in Section 3.2.3. The analysis presented at this Final RD phase is based on a M of 9.08 and R of 75.5 kilometers, which is associated with a full rupture of the CSZ.

4.1.3 Liquefaction Potential Index

Liquefaction Potential Index (LPI) represents the liquefaction severity (damage potential) based on the cumulative liquefaction response of a given profile (NASEM, 2016). LPI can range from 0 to 100. LPI <5 generally indicates little liquefaction occurred while LPI >15 shows severe liquefaction (Iwasaki et al., 1978). The majority of the LPI values estimated as part of the liquefaction analysis exceed 15, indicating the probable occurrence of severe liquefaction (high liquefaction risk).

4.1.4 Liquefaction Induced Settlement

Liquefaction-related shear and volumetric strains are correlated to the results of liquefaction triggering analyses by Ishihara and Yoshimine (1992) and many others. The Ishihara and Yoshimine (1992) procedure was used to estimate the volumetric strain as a function of factor of safety against liquefaction, relative density, and normalized CPT tip resistance.

Estimated seismic settlement at in-water CPTs ranged from 3.2 to 15.9 inches (8.1 to 40.4 centimeters [cm]), with the maximum estimated seismic settlement of 15.9 inches (40.4 cm) observed at SCPTW-11.

It is noted that the empirical model (Ishihara & Yoshimine, 1992) used herein was developed based on laboratory test data of clean sands and hence, the estimated settlements are generally considered conservative for the in situ soils with fines similar to the Project Area.

Estimates of liquefaction induced settlement are included in each CPT based liquefaction analysis report presented in Attachment B and on Figure 4-1.

4.1.5 Liquefaction Induced Lateral Spreading

Lateral spreading is a potential hazard commonly associated with liquefaction where extensional ground cracking and settlement occurs as a response to lateral migration of subsurface liquefiable

material. These phenomena typically occur adjacent to free faces such as slopes that surround the majority of SIB.

For a given SPT or CPT profile, Lateral Displacement Index (LDI) was computed from maximum shear strains (γ_{max}) by the following equation from Zhang et al. (2004):

$$LDI = \int \gamma_{max}\, dz$$

Youd et al. (2001) suggests the depth threshold of 23 m (about 75 ft) below ground surface as a validated range for CPT-based methodology when computing LDI. Then, the empirical correlations from Zhang et al. (2004) were used to estimate liquefaction-induced lateral displacement from LDI considering topography effects from free face nearby (based on L/H) and site's ground slope (based on S) as follows.

$$LD_{free\ face} = 6\ LDI\ \left(\frac{L}{H}\right)^{-0.8}\ where\ 4 < \frac{L}{H} < 40$$

$$LD_{Ground\ Slope} = LDI\ (S + 0.2)\ where\ 0.2 < S < 3.5$$

where L is the distance between the free face to the location of interest; and H is the depth of free face; S is the site's ground slope (%). The overall trendline from these empirical equations shows that lateral displacement (LD/LDI) decreases with decreasing S (less ground sloping) and increasing distance to height ratio of free face (L/H). It is noted that there are applicable ranges in terms of L/H ratio and S values stemming from the limited case history data based on which the empirical models were developed.

A total of 20 data were used in estimating the lateral spreading displacements: 16 SPTs and 4 SCPTs. However, most of the data were out of the applicable range of the L/H ratio (below 4; i.e., too close to the free face) except for only three SPT data: B-06, B-07, and B-09 with their ratios of 4.5, 4.7, and 6.6, respectively.

It is noted that the Zhang et al. model was developed based on data from free faces without engineered structures (retaining walls, quay walls). With the slopes of this Project Area including engineered structures, the estimates from the Zhang et al. model are considered overly conservative and lower lateral displacements than the model's estimates are anticipated.

4.1.6 Liquefaction and Lateral Spreading Design Considerations

Based on the magnitude and variability of the potential ground deformation associated with both CLE and DE level seismic events, differential horizontal and vertical displacement of sediment caps and riverbank slopes should be anticipated over the design life of the RA and could lead to exposure of contaminated sediment.

Mitigating measures to avoid exposure of capped materials following a CLE have been considered, and where possible have been incorporated into the RD. These measures include slope reconfiguration and reconstruction, structural elements including retaining walls and pinning piles, as well as the use of geotextiles. The incorporation of these mitigating measures into the RD will help limit the potential for exposure of capped materials following a CLE level seismic event, SIB Project Area-wide mitigation of earthquake-induced soil liquefaction, specifically for liquefaction

induced settlement and for ground motions that exceed CLE parameters, is not practical and would likely be ineffective with regard to chemical isolation.

The RA Operations and Maintenance Plan should include a post-seismic event maintenance and repair plan that establishes, at a minimum, a cap monitoring methodology and frequency, proposed ground motion triggers for post-event cap inspections, and target durations for cap repair after damaging earthquake events.

4.2 SEDIMENT CAP DESIGN

Geotechnical aspects of cap design and the underlying sediment were considered as part of the RD. These considerations are crucial in capping because contaminated sediments are typically fine-grained and may have high water content and low shear strength (Palermo et al., 1998a). Geotechnical analysis was driven by the hypothetical chemical isolation and erosion protection layer alternatives presented in the Cap Design Technical Memorandum, and the guidance described in the RDGC (EPA, 2021b) and *Guidance for In-Situ Subaqueous Capping of Contaminated Sediments* (Palermo et al., 1998b). Geotechnical considerations evaluated for cap stability included:

- Representative section development and identification of risks and failure modes;
- Bearing capacity analysis;
- Settlement analysis;
- Filter design;
- Evaluation of liquefaction susceptibility; and
- Static and pseudo-static cap stability analysis.

4.2.1 Bearing Capacity

Bearing capacity of near-surface sediment material was evaluated using methods described in *Guidance for In-Situ Subaqueous Capping of Contaminated Sediments* (Palermo et al., 1998b). The analysis methodology is based on fundamental bearing failure equations (Terzaghi and Peck, 1967) and provides an estimated maximum allowable cap lift thickness based on the unit weight of the proposed cap, the undrained shear strength of the underlying sediment, and includes a factor of safety of 3.0. Further details on the bearing capacity calculation are provided in Attachment C.

Based on the bearing capacity calculation presented in Attachment C, an initial maximum lift thickness of 3.5 ft may be placed while maintaining the target FoS. To ensure stability and mitigate localized bearing failures, the construction team should adopt an observational approach, regularly assessing activities and progress. If bearing capacity issues arise, adjustments such as slower material placement or thinner application layers may be necessary.

4.2.2 Consolidation Settlement

Consolidation settlement of the cap supporting sediment material was evaluated using Settle3 by Rocscience, a commercially available settlement analysis program. The Settle3 model allows for caps loads to be applied in stages, in accordance with the planned construction sequencing and timing, and computes both elastic settlement and heave (rebound), and time-dependent

consolidation settlement. Settlement analysis, based on an assumed uniform cap load applied in a single stage was developed to estimate the approximate, total, post-construction settlement of an engineered sediment cap. The cap settlement model was based on the project ground model and geotechnical design parameters discussed in Section 3.1. The granular composition of the cap material ensures that it does not undergo consolidation settlement itself and therefore not discussed further.

Settlement analysis indicates that, under a load equivalent to a 3.5-ft cap lift, approximately 20 inches of total consolidation settlement (including both primary and secondary settlement) is expected under worst-case ground conditions at the head of SIB, where compressible sediments are thickest. This estimate reflects conservative assumptions and ensures that the design accounts for both immediate and long-term settlement behavior of the underlying soils, supporting cap performance across the Project Area. Additional details on consolidation parameters, assumptions, and calculation methodology are provided in Attachment C

Variations in compressible sediment thickness and net loading changes (dredge thickness versus cap placement) across the Project Area can lead to differential subgrade settlement. The dominant source of variability in the settlement response is the extent dredging occurs prior to cap placement. Dredging directly controls the net vertical effective stress change on the underlying compressible sediments at the time of capping, for example:

- If no dredging is performed, the full cap thickness represents a net load increase on the subgrade, and settlements approach the worst-case consolidated values summarized above (approximately 20 inches under the head-of-SIB model).
- If dredging depth is approximately equal to the cap thickness, the net stress change is reduced, resulting in minimal to moderate consolidation settlement proportional to the residual net load from differences in weight of cap materials to the replaced sediment.
- If dredging exceeds the cap thickness, the net increase in stress on the underlying sediments is zero or negative, and consolidation settlement of the underlying sediments is expected to be negligible.

The differential settlement noted above may result in surficial undulation of the cap. Based on the estimated magnitude of differential subgrade settlement across the Project Area and the dredging geometry presented in the design, the associated undulation of the cap surface is not anticipated to compromise the overall performance or functionality of the cap.

The settlement of the cap and discussed undulation can affect interpretation of bathymetric survey data used to confirm cap thickness. Settlement may be misread as cap “thinning” when surveys are interpreted. Integrating thickness probing with routine bathymetric surveys will help ensure that maintenance decisions are based on accurate interpretations of settlement and cap integrity, supporting long-term stability and effectiveness of the environmental cap.

4.2.3 Filter Design

Grain size compatibility between cap materials and native sediment was evaluated with respect to the potential for vertical migration of both sediment and cap materials. Filter design was evaluated

based on *Gradation Design of Sand and Gravel Filters* (USDA, 2017). Sediment soils evaluated included elastic silt (MH) from BW-15 (sample #2 at 3 ft [90 cm]), which is representative of the controlling material type with respect to grain size compatibility between cap materials and native sediment. Sand cap material was based on Oregon Department of Transportation (ODOT) fine concrete aggregate (based on Table 02690-5). The erosion protection material (gravel) evaluated was based on ODOT coarse concrete aggregate (ODOT, 2024), which is comprised primarily of aggregates with a nominal size of less than 1 inch and greater than the aperture of a #4 sieve. The gravel material evaluated in the filter design is consistent with the erosion protection material for Cap Type 1 (habitat gravel). Erosion protection material for Cap Type 2 (3-inch median diameter angular rock) was also evaluated and determined to be compatible with the underlying sand in the filter analysis. The materials evaluated for the filter design are consistent with erosion protection requirements described in the Cap Design Technical Memorandum (Volume I, Appendix E) and the project specifications.

Filter design analysis results indicate that the anticipated cap material types adequately limit the potential of vertical migration of both sediment and cap materials.

4.2.4 Cap Slope Stability

In-water sediment cap slope stability was evaluated with 2D limit-equilibrium analysis using Slide2 by Rocscience and based on a minimum static factor of safety of 1.5, and a minimum pseudo-static (non-liquefied) factor of safety of 1.1 (ODOT, 2024). Additionally, the potential for liquefaction-induced flow failure (cap material section only) was evaluated using conventional limit equilibrium slope stability analyses and residual undrained shear strength parameters for the liquefied cap material (analysis decoupled from all seismic inertial forces). Static 2D limit-equilibrium analysis results were also checked against infinite slope chart solutions for general agreement.

A horizontal seismic coefficient of 0.12 was used in pseudo-static stability analyses. The horizontal seismic coefficient was estimated as a half of the mapped peak ground acceleration (ODOT, 2024) of 0.234 g (2018 Conterminous U.S. National Seismic Hazard Map) for a CLE seismic event (10 percent probability of exceedance in 50 years, 475-year return period) and does not include a slope height reduction factor.

Design of in-water caps should be based on slope gradients of approximately 3 horizontal to 1 vertical ratio (3H:1V) (±19 degrees) or flatter. Details regarding the stability evaluations performed as part of the riverbank slope design process, including engineered caps on slopes that are steeper than 3H:1V, are discussed in Section 4.3 and Attachment C.

4.3 RIVERBANK SLOPES

The stability of riverbanks, both above and below the water level, has been assessed to evaluate the effectiveness of the RD. This assessment is essential for understanding the localized impacts on the design and implementation of remedial activities.

In most locations within the SIB Project Area, the RD entails the removal, grading, and placement of material on existing riverbanks. The following section outlines the considerations for global slope stability for the Pre-Final 90% RD.

4.3.1 Slope Stability

The slope design has been undertaken based on an RD focused on the removal of soil exceeding remedial action levels, while limiting the impact on existing marine structures (i.e., no net change in loading condition on existing structures).

The existing riverbanks have been assessed to be currently marginally stable, with localized areas of instability. The riverbank reconnaissance conducted during the PDI noted multiple areas of surficial soil movements (HGL, 2024). Slope stability analysis has been undertaken for the existing and proposed remedial conditions and reported in Attachment C. The results of the stability analyses confirmed that some of the existing slopes will require reconfiguration as part of the RD. The aim of the reconfiguration is to flatten the slopes to a stable angle, while limiting the impact on the shoreline and overwater structures.

4.3.2 Riverbank Stability Analysis

Slope stability has been assessed using the factor of safety (FoS), which is the ratio of resisting forces or moments to driving forces or moments. As the FoS nears 1.0, deformation increases and becomes uncontrollable at unity (1.0). Fine-grained soils, being sensitive to loading timing and rate, necessitate categorizing slope stability analyses into short-term and long-term loading. For stability, slopes require a minimum FoS of 1.3 during short-term construction loading, and a minimum FoS of 1.5 during long-term static conditions.

Each design area has been evaluated using existing geometry, stratigraphy, and groundwater conditions. Slope stability analysis details, and analysis output cross-sections for select design reaches are presented in Attachment C.

In general, a maximum slope gradient of 2.5H:1V and 2.75H:1V is recommended for both temporary and permanent unreinforced riverbank slopes. Riverbank slope design recommendations are summarized in Table 4-1 and presented graphically on Figure 4-2.

4.4 SHORELINE AND OVERWATER STRUCTURES

Each structure within the SIB Project Area has been assessed against the RD requirements for dredging, capping, and geotechnical stability. Where applicable, measures have been designed to maintain functionality and mitigate against the risk of damage to the structure. In some cases, to achieve the Remedial Action Objectives (RAOs), toe walls or other slope stabilizing structures have been designed. In cases where slope stabilization methods are not sufficient, the complete removal/replacement of structures has been specified. A detailed summary of the design considerations and design outcomes for all structures within the SIB Project Area is presented in Volume I, Appendix J (Structural Design Technical Memorandum).

The new and existing structures within the SIB Project Area have been assessed for geotechnical stability. The new structures required to achieve both slope stability and RAOs included a new toe

wall at the USCG, slope stabilization pinning walls at the Marine Consortium, rock buttressing at Quay Wall and Pier A, and replacement of functional structures (Berth 306 and Berth 307) (Attachment D). The geotechnical assessment for existing structures impacted by RD requirements, including Pier A and Quay Wall, is presented in detail in Attachment E.

5.0 CONSTRUCTION AND MONITORING CONSIDERATIONS

5.1 CONSTRUCTION

A pre-construction survey should be performed prior to the start of construction to document the existing condition of structures, improvements, walls, and utilities within the SIB Project Area.

The pre-construction survey should include a topographic survey and photographs that adequately document the existing conditions. If appropriate, diagrams and sketches of the distressed areas should be included. The photographs and any supporting documents should be catalogued for each existing facility where data was collected. The pre-construction survey should be performed in accordance with the Project Specifications (Section 02 21 00) and will serve as a baseline for the assessment of slope deformation and structural deflection or distress observed during or following construction.

Construction activities could result in excessive deformations or ground losses that lead to vertical settlements adjacent to excavations, which may affect adjacent structures. Instrumentation should be installed to monitor the response of the ground and adjacent structures, utilities, and pavement to construction activities. Settlement Monitoring Points (SMs) should be installed and monitored in accordance with Specification Section 31 09 00.

5.2 POST CONSTRUCTION

The newly constructed slopes and sediment cap will be exposed to significant hydraulic forces shortly after installation. To establish a reference condition, a baseline survey of the slope erosion protection features and the sediment cap should be conducted immediately following construction. This baseline will serve as a benchmark for future evaluations of slope and cap performance. The same features should be reassessed during each 5-year review cycle to verify continued effectiveness. Slope protection elements should be inspected for signs of damage or degradation after each major storm event.

5.3 SEISMIC HAZARD OPERATION AND MANAGEMENT

Liquefaction-induced deformations resulting from a CLE event could significantly compromise the performance of remedial design measures, including both riverbank slopes and the in-water sediment cap. A common and effective mitigation strategy could involve ground improvement techniques such as deep soil mixing. However, due to the depth and extent of potentially liquefiable materials within the SIB project area, a design that completely mitigates the seismic hazards associated with a CLE event is not practical from a cost and constructability perspective. A more practicable and readily implementable alternative, such as a strategy that uses a timely, post-event inspection and maintenance/repair, should be implemented to identify and then address potential damage following seismic shaking that could trigger liquefaction.

Table 3-1
Geotechnical Parameters for Design
Geotechnical Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Engineering Soil Unit	Material Behavior	Bulk Unit Weight γ (pcf)	Angle of Internal Friction φ' (degrees)[a]	Cohesion c' (psf)	Undrained Shear Strength Su (psf)	Residual shear strength ratio for liquefied soils	C'c	C'r	k (ft/year)[c]	K0	Poisson's Ratio (v)
Artificial Fill	Cohesionless	110	32 – 36	0	-	0.131	-	-	-	0.45	0.3
Recent Basin Sediment – Mocks Bottom	Cohesionless	105	32 – 34	0	-	0.161	-	-	-	0.45	0.35
Recent Basin Sediment – Swan Island	Cohesive	95	30 – 33	0	200 - 300	0.161	0.9	0.08	0.103 – 10.3	0.47	0.45
Alluvium – Sand	Cohesionless	115 @ EL ≥ 0 ft 120 @ EL < 0 ft	32 – 34 @ EL ≥ -10 ft 34 – 36 @ EL < -10 ft	0	-	0.131	-	-	-	0.45	0.25
Alluvium – Clay	Cohesive	105	24 – 26	0 - 75	800 @ EL ≥ -5 -20(EL+5) + 800 @ EL < -5 (max 1450 psf)	0.131	0.5	0.03	0.103 – 10.3	0.58	0.40
Missoula Flood Deposits – Silt	Cohesive	110	31 – 33	0 - 150	<u>Mocks Bottom</u> 1100 @ EL ≥ -8 -10(EL+8) + 1100 @ EL < -8 (max 1500 psf)	0.131	0.45	0.03	10.3	0.47	0.40
					<u>Swan Island</u> 1500 @ EL ≥ -8 -25(EL+8) + 1500 @ EL < -8 (max 2500 psf)				10.3		
Missoula Flood Deposits - Sand	Cohesionless	120	33 - 35 @ EL ≥ -80 ft 35 - 38 @ EL < -80 ft	0	-	0.131	-	-	-	0.45	0.30

<u>Footnotes:</u>
a) Sensitivity checks - range has been provided for sensitivity analyses based on the potential for variability within the project wide engineering units
b) Parameters have been derived for the geotechnical design of riverbank stability, preliminary lateral pile analysis, and sediment cap design (bearing capacity and settlement).
c) Permeability been used to determine the coefficient of consolidation for time-dependent settlement analysis. Refer to Attachment A for further detail.

<u>Acronyms and Abbreviations:</u>
≥ = greater than or equal to
< = less than
ϕ' = internal friction
c' = effective cohesion
C'c = compression index
C'r = recompression index
k = permeability
EL = Elevation in NAVD88
ft = feet
Ko = at-rest earth pressure coefficient
NAVD88 = North American Vertical Datum of 1988
pcf = pounds per cubic foot
psf = pounds per square foot
Su = Undrained shear strength

Table 4-1
Summary of Slope Design Recommendations
Geotechnical Design Technical Memorandum; Swan Island Basin Project Area, Portland, Oregon

Location Identification	Approximate Station	Existing Slope Conditions	Existing Structures [a]	Max existing slope gradient (approx.)	Max top of Slope elevation (approx.) - ft	Proposed dredge elevation at toe - ft	Proposed On-slope material	Proposed slope gradient [b] (H:V)	Proposed Structures [c]
Mocks Bottom									
USCG	47 – 53	Rooted vegetation, exposed slope at waterline	USCG Pier and Floating Dock	2.2H:1V	34	-6	3 ft riprap and bedding. GAC geotextile	2.75H:1V	Toe wall between USCG pier and floating dock
Navy	41 – 47	Rooted dense vegetation. Riprap from approx. 3ft above OHW to unknown depth	Navy Pier	2.4H:1V	38	-14	3 ft riprap and bedding. GAC geotextile	2.5H:1V	-
MC	32 – 41	Riprap above and below OHW	MC Pier	2.1H:1V	38	-14	3 ft riprap and bedding. GAC geotextile	2.15H:1V	Two rows of pinning piles
								2.5H:1V	-
Port of Portland, Dredge Base	22 – 32	Rooted dense vegetation. Riprap present below OHW	Dredge Base Pier	2.5H:1V	38	-9	3 ft riprap and bedding. GAC geotextile	2.5H:1V	-
ATC Leasing	17 – 22	Heavily vegetated with some riprap. Sand beach present at waterline	-	1.7H:1V	36	-19	3 ft riprap and bedding. GAC geotextile with planting above OHW	3H:1V	-
Swan Island Dock Company, Berth 311	0 – 17	Heavily vegetated with sparse riprap. Sand beach present at waterline	Berth 311 Pier	<3H:1V	38	-19	3 ft riprap and bedding. GAC geotextile with planting above OHW	3H:1V	-
Head of SIB									
Head of SIB	-1 – 0	Sand bank, limited vegetation and riprap	Boat Ramp	<3H:1V	36	Not required	Riprap, GAC geotextile with planting above OHW	3H:1V	-
Swan Island									
Freightliner Wind Tunnel	0 – 6	Wood retaining wall. Riprap present below OHW	Wind tunnel	1.7H:1V	36	Not required	3 ft riprap and bedding. GAC geotextile with planting above OHW	3H:1V	-
Berths 306, 307 & 308	6 – 21	Engineered bank, riprap below OHW	Timber Piers and Dolphins	1.7H:1V	36	-14	3 ft riprap and bedding. GAC geotextile with planting above OHW	2.5H:1V	New berth structure and dolphins
Lagoon Wharf	21 – 41	Sheet pile wall with steep slope in front	Timber piers and slopes	>1H:1V	37	-25	3 ft riprap and bedding. GAC geotextile	2.5H:1V	New berth structure with anchored retaining structures
Pier A and Quay Wall	41 – 67	Sheet pile wall / diaphragm cells	Pier A and Quay Wall	n/a	35	-51	n/a	n/a	-
SCC Floating Dock	67 - 69	Vegetated slope above OHW, riprap below	Floating dock	1.7H:1V	36	-51	3 ft riprap and bedding. GAC geotextile	2.75H:1V	-
Demo Pier	69 -	Vegetated slope above OHW, riprap below	Pier structures	1.6H:1V	37	-56	3 ft riprap and bedding. GAC geotextile	2.75H:1V	-

Notes:
a) For further details on marine structures refer to Structural Design Technical Memorandum.
b) Proposed slope gradients are overall slopes required for global stability.
c) Final slope gradients temporary slopes during construction not to be greater than 1V:2.5H with a slope height limit of 10 ft.

< = less than
ft = feet
GAC = Granular activated carbon
H:V = horizontal to vertical ratio
OHW = ordinary high water
MC = The Marine Consortium, Inc.

NAD83 = North American Datum 1983
NAVD88 = North American Vertical Datum of 1988
SCC = Shipyard Commerce Center
SIB = Swan Island Basin
USCG = U.S. Coast Guard

ATTACHMENT A
GEOTECHNICAL DESIGN PARAMETERS

1.0 INTRODUCTION

The following attachment summarizes the geotechnical information and its interpretations to characterize ground conditions at the Swan Island Basin (SIB) Project Area within the Portland Harbor Superfund Site in Portland, Multnomah County, Oregon. These parameters have been derived for the geotechnical design of riverbank stability, preliminary lateral pile analysis, and sediment cap design (bearing capacity and settlement).

The design parameters have been developed based on the available information, which included: the results of the in situ and laboratory testing from field investigations, soil descriptions from borehole logs in the SIB Project Area, groundwater data, and published case history information from relevant sources.

2.0 PROJECT STRATIGRAPHY

The stratigraphy encountered in the SIB Project Area was divided into seven Engineering Soil Units (ESUs) based on geologic depositional cycles.

- **Artificial Fill**: primarily dredged material consisting of a mixture of recent basin sediments, alluvium sand, alluvium clay, and fine to coarse gravel. Poorly graded sand with silt to silty sand with channels of poorly graded sand with clay to clayey sand. Layers of poorly graded gravel were occasionally encountered.
- **Recent Basin Sediment - Mocks Bottom**: silty sand, low plasticity silt.
- **Recent Basin Sediment - Swan Island**: high plasticity silt.
- **Alluvium - Sand**: poorly graded sand to silty sand.
- **Alluvium - Clay**: sandy lean to fat clay.
- **Missoula Flood Deposits – Silt**: low plasticity silt to sandy silt.
- **Missoula Flood Deposits – Sand**: poorly graded sand to silty sand.

Index properties and gradation for each ESU have been reviewed across the entire SIB Project Area to check consistency of ESUs across the project area. The review indicated that the index properties and gradation of each ESU are generally consistent throughout the project area except for the following trends:

- **Artificial Fill** was not encountered in the in-water basin of the project area.
- **Recent Basin Sediments** were not encountered in upland positions at Mocks Bottom. Silty Sand (SM) and Silt (ML) were primarily encountered along the Mocks Bottom basin waterfront. Elastic Silt (MH) was primarily encountered along the SIB waterfront and west Swan Island piers. Based on these observations the Recent Basin Sediments ESU was divided into two ESUs.
- **Alluvium - Clay** deposits were not encountered at Swan Island.
- **Missoula Flood Deposits – Silt** is generally high plasticity at higher elevations. Plasticity decreases with elevation to about -30 feet (ft) elevation to medium plasticity (PI = 10).

Plasticity decreases and sand content increases from Mocks Bottom to Swan Island.

- **Missoula Flood Deposits – Sand** is generally silty sand above -75 ft elevation and poorly graded sand with silt below -75 ft elevation.

3.0 GEOTECHNICAL PARAMETER DERIVATION

The parameters used in the Remedial Design (RD) are summarized in Table 3-1 of the Geotechnical Design Technical Memorandum (GDTM). This attachment outlines the derivation of key preliminary geotechnical parameters. The parameters presented may not be applicable to all design scenarios.

Table 3-1
Summary of Laboratory Testing

Test		Count	Maximum	Minimum	Average
Moisture Content (%)		340	101.9	1.8	34.2
Total Unit Weight (pcf)		177	132.8	65.3	109.3
Atterberg Limits [a]	Liquid Limit (%)	123	102.0	28.0	50.3
	Plastic Limit (%)	123	60.0	18.0	33.9
	Plasticity Index (%)	123	52.0	1.0	16.4
Particle Size Distribution	Gravel (%)	154	91.0	0.0	3.8
	Sand (%)	156	98.5	1.6	72.4
	Fines (Silt + Clay) (%)	203	99.0	1.5	36.9
	Clay (%)	98	21.1	0.2	5.4
	Silt (%)	98	80.0	1.6	16.9
TXUU – S_u (psf)		52	3750.0	120.0	1180.0
TXCU – Effective Stress φ'		15	36.0	0.0	30.4
DSS – Total Stress φ		11	27.6	18.9	25.0
DS – Effective Stress φ'		17	40.9	22.8	34.3
1D Consolidation (IL)		50	-	-	-

Note:
a) The total number of Atterberg limits tests completed is presented. The maximum, minimum, and average values exclude 37 tests which returned non-plastic results.
% = percent
φ = effective friction angle
pcf = pounds per cubic foot
psf = pounds per square foot
IL = incremental loading

3.1 CLASSIFICATION TESTS

3.1.1 Moisture Content

Moisture content was determined from disturbed and undisturbed samples collected for a variety of laboratory tests (e.g., moisture density, consolidation, triaxial, direct shear).

Table 3-2
Moisture Content Data by ESU

ESU	Count	Maximum (%)	Minimum (%)	Average (%)
Artificial Fill	59	44.7	1.8	15.4
Recent Basin Sediment – Mocks Bottom	8	51.6	24.8	39.7
Recent Basin Sediment – Swan Island	28	101.9	21.0	68.8
Alluvium – Sand	33	50.6	3.9	26.8
Alluvium - Clay	27	72.3	31.8	49.6
Missoula Flood Deposits – Silt	79	67.6	18.0	41.6
Missoula Flood Deposits – Sand	106	54.7	5.7	28.0

Notes:
ESU = Engineering Soil Unit

Moisture content is generally consistent with elevation for each ESU except for recent basin sediments which have a large standard deviation.

3.1.2 Atterberg Limits

Table 3-3
Atterberg Limits Data by ESU

ESU	Test Count	Tests Non-plastic	Liquid Limit (%)			Plasticity Index (%)		
			Max	Min	Avg	Max	Min	Avg
Artificial Fill	10	5	47	29	39	13	4	8
Recent Basin Sediment – Mocks Bottom	1	0	-	-	47	-	-	12
Recent Basin Sediment – Swan Island	23	2	102	35	72	52	5	30
Alluvium – Sand	10	6	44	28	36	10	1	6
Alluvium - Clay	11	0	62	35	51	32	12	24
Missoula Flood Deposits – Silt	52	10	76	30	43	34	1	11
Missoula Flood Deposits – Sand	16	14	29	28	29	3	2	3

Notes:
Avg = average
Max = maximum
Min = minimum

The Unified Soil Classification System (USCS) classification of the material encountered in each ESU was reviewed to validate the ESU.

- **Artificial Fill** is composed primarily of poorly graded sand (SP), with occasional layers of SILT (ML) and poorly graded GRAVEL (GP).
- **Recent Basin Sediment – Mocks Bottom** is composed of poorly graded sand with silt or

clay, occasional layers of Sandy SILT (ML) and CLAY (CL).

- **Recent Basin Sediment – Swan Island** is composed primarily of Elastic SILT (MH) with occasional sand deposits including Silty SAND (SM) and Clayey SAND (SC).
- **Alluvium – Sand** is composed of primarily poorly graded sand. Occasional layers encountered were recorded as Poorly graded GRAVEL (GP-GM)
- **Alluvium - Clay** is composed entirely of medium to high plasticity clay.
- **Missoula Flood Deposits – Silt** is composed of primarily medium plasticity sandy silt. Few layers of Elastic SILT (MH) were also encountered.
- **Missoula Flood Deposits – Sand** is composed entirely of poorly graded sand.

3.1.3 Particle Size Distribution

Table 3-4
Particle Size Distribution Data by ESU

ESU	Test Count [a]	Average Values [a]				
		Gravel (%)	Sand (%)	Fines (%)	Silt (%)	Clay (%)
Artificial Fill	30	9	72	18	13	5
Recent Basin Sediment – Mocks Bottom	24	0	89	11	8	5
Recent Basin Sediment – Swan Island	1	0	41	59	14	6
Alluvium – Sand	21	7	76	17	17	4
Alluvium - Clay	9	9	29	62	50	13
Missoula Flood Deposits – Silt	40	0	35	65	54	13
Missoula Flood Deposits – Sand	78	2	82	16	12	4

Notes:
a) Total number of tests including Grain Size Distribution (ASTM D613), Percent Passing No. 200 Sieve (ASTM D1140) and Hydrometer Analysis (ASTM D7928)
b) The total of silt and clay percentages do not always equal the fines percentage. This occurs because the results shown are an average of both Hydrometer and particle size distribution test results.

Based on the USCS classification of materials encountered, Atterberg limit data, and particle size distribution data, the following USCS classification is representative of each ESU.

- Artificial Fill — Silty SAND (SM)
- Recent Basin Sediment – Mocks Bottom — Silty SAND (SM)
- Recent Basin Sediment – Swan Island — Elastic SILT with SAND (MH)
- Alluvium – Sand — Silty SAND (SM)
- Alluvium – Clay — Fat CLAY with SAND (CH)
- Missoula Flood Deposits – Silt — Sandy SILT (ML)
- Missoula Flood Deposits – Sand — Silty SAND (SM)

3.2 BULK UNIT WEIGHT

Values of bulk unit weight have been determined based on the following:

- Initial bulk density from test results (for example Triaxial and Shear Box testing), multiplied by g (acceleration due to gravity); and
- Comparison against parameters presented in published literature based on descriptions and in situ density measurements.

The laboratory testing and recommended bulk unit weight values are presented for each ESU in Table 3-5.

Table 3-5
Bulk Unit Weight Data by ESU

ESU	Test Count	Maximum (pcf)	Minimum (pcf)	Average (pcf)	Recommended (pcf)
Artificial Fill	29	127.7	80.6	109.4	110
Recent Basin Sediment – Mocks Bottom	5	113.8	86.4	105.6	105
Recent Basin Sediment – Swan Island	21	115.1	65.3	93.6	95
Alluvium – Sand	14	132.8	105.0	117.5	115 @ EL ≥ 0 ft 120 @ EL < 0 ft
Alluvium - Clay	22	116.2	83.6	104.8	105
Missoula Flood Deposits – Silt	49	121.3	96.8	108.8	110
Missoula Flood Deposits – Sand	37	131.4	101.2	118.7	120

Notes:
ft = feet/foot
EL = elevation

3.3 DRAINED SHEAR STRENGTH

Values of effective angle of shearing resistance and effective cohesion have been determined for both the coarse and fine material across the project site.

Coarse material:

- Direct shear test results;
- Direct simple shear test results;
- Cone Penetration Test (CPT) correlations from CPeT-IT per Guide to Cone Penetration Testing for Geotechnical Engineering (Robertson, 2015); and
- Relationship between Standard Penetration Test (SPT) blow count $(N_1)_{60}$ presented in the Caltrans Geotechnical Manual (2021) reproduced from Bowles (1977).

Fine material:

- Consolidated Undrained Triaxial (with pore water pressure measurements) test results

(TXCU); and

- CPT correlations from CPeT-IT per Guide to Cone Penetration Testing for Geotechnical Engineering (Robertson, 2015).

Test results are presented in Tables 3-6 through 3-8.

Table 3-6
TXCU Data by ESU

ESU	Test Count	Effective Cohesion (psf)			Effective Friction Angle φ'		
		Max	Min	Avg	Max	Min	Avg
Artificial Fill	0	-	-	-	-	-	-
Recent Basin Sediment – Mocks Bottom	0	-	-	-	-	-	-
Recent Basin Sediment – Swan Island	1	-	-	0	-	-	32
Alluvium – Sand	0	-	-	-	-	-	-
Alluvium - Clay	6	540	0	200	36	27	32
Missoula Flood Deposits – Silt	8	380	0	165	36	30	33
Missoula Flood Deposits – Sand	0	-	-	-	-	-	-

Table 3-7
Direct Shear Data by ESU

ESU	Test Count	Effective Cohesion (psf)			Effective Friction Angle φ'		
		Max	Min	Avg	Max	Min	Avg
Artificial Fill	1	-	-	250	-	-	35
Recent Basin Sediment – Mocks Bottom	2	250	0	125	40	38	39

Alluvium - Clay	1	-	-	270	-	-	33
Missoula Flood Deposits – Silt	3	1,860	0	787	34	23	29
Missoula Flood Deposits – Sand	7	1,310	0	427	37	30	33

Table 3-8
Direct Simple Shear Data by ESU

ESU	Test Count	Cohesion (psf)			Friction Angle φ		
		Max	Min	Avg	Max	Min	Avg
Artificial Fill	0	-	-	-	-	-	-
Recent Basin Sediment – Mocks Bottom	1	-	-	140	-	-	24
Recent Basin Sediment – Swan Island	1	-	-	0	-	-	27
Alluvium – Sand	3	270	0	103	28	19	24
Alluvium - Clay	0	-	-	-	-	-	-
Missoula Flood Deposits – Silt	1	-	-	110	-	-	22
Missoula Flood Deposits – Sand	5	0	0	0	28	23	26

The drained shear strength parameters in Table 3-9 are recommended. A range has been provided for sensitivity analyses based on the potential for variability within the project wide engineering units.

Table 3-9
Recommended Drained Shear Strength Parameters

ESU	φ'_{peak} (°)	c' (psf)
Artificial Fill	32 – 36	0
Recent Basin Sediment – Mocks Bottom	32 – 34	0
Recent Basin Sediment – Swan Island	30 – 33	0
Alluvium – Sand (EL ≥ -10 ft)	32 – 34	0
Alluvium – Sand (EL < -10 ft)	34 – 36	0
Alluvium - Clay	24 – 26	0 - 150
Missoula Flood Deposits – Silt	31 – 33	0 - 150
Missoula Flood Deposits – Sand (EL ≥ -80 ft)	33 – 35	0
Missoula Flood Deposits – Sand (EL < -80 ft)	35 – 38	0

Notes:
° = degrees

3.4 UNDRAINED SHEAR STRENGTH

Undrained shear strength for fine soils has been determined from the following tests and relationships.

- Undrained triaxial compressions tests (TXUU); and
- In situ CPT values of undrained shear strengths calculated from the corrected cone resistance (q_c) measured during the CPT's. The undrained shear strength values have been

calculated using the following formula where σ_{v0} is the total vertical stress, and N_{kt} is dependent on both the plasticity index and the structure of the soil. A range of N_{kt} values were used (12 – 14) in the correlation with undrained shear strength.

$$c_u = \frac{q_c \times \sigma_{v0}}{N_{kt}}$$

The laboratory testing and recommended undrained shear strength values are presented for each fine ESU in Table 3-10.

Table 3-10
Undrained Shear Strength Data by ESU

ESU	Test Count	S_u (psf) - TXUU			Design recommendation
		Max	Min	Avg	Undrained Shear Strength (psf)
Artificial Fill	0	-	-	-	-
Recent Basin Sediment – Swan Island	16	2,340	120	486	200 - 300
Alluvium - Clay	8	1,770	480	1,209	800 @ EL ≥ -5 -20(EL+5) + 800 @ EL < -5 (max 1,450 psf)
Missoula Flood Deposits – Silt	24	3,750	720	1,617	<u>Mocks Bottom</u> 1100 @ EL ≥ -8 -10(EL+8) + 1,100 @ EL < -8 (max 1,500 psf) <u>Swan Island</u> 1500 @ EL ≥ -8 -25(EL+8) + 1,500 @ EL < -8 (max 2,500 psf)

3.5 RESIDUAL SHEAR STRENGTH OF LIQUEFIED SOIL

Residual shear strength of liquefied soil was evaluated to support seismic stability assessments in areas underlain by potentially liquefiable soils. Empirical correlations for SPT and CPT data (Idriss and Boulanger, 2008) were used for this evaluations.

Residual Strength Ratio:

- SPT derived normalized residual shear strength ratio of liquefied soil ranged from 0.04 to 0.74.
- CPT-derived residual shear strength ratios ranged from 0.04 to 0.84, with an average of 0.156.
- It is considered that these ranges are consistent with published expectations for liquefied soils and reflect the inherent variability in empirical methods.

Given the depositional and reclamation history of the site, differing values were adopted for on-shore and off-shore areas:

- On-shore areas (e.g., Mocks Bottom or Swan Island slopes), a residual strength ratio of

0.131 was selected.

- In-water soils (e.g., Swan Island Basin), a higher residual strength ratio of 0.161 was applied.

These values reflect the effects of dredging, fill placement, and differences in the material deposition across the site.

3.6 COMPRESSION AND RECOMPRESSION INDICES

Values of compression index (C_c) and recompression index (C_r) have been determined from one-dimensional tests. The determined values were compared against typical values presented in NAVFAC DM 7.1 (NAVFAC, 2022).

The laboratory testing and recommended design values for fine-grained material are presented in Table 3-11 and Table 3-12.

Table 3-11
Compression Indices test results

ESU	Test Count	Cc – OD			Cr – OD		
		Max	Min	Avg	Max	Min	Avg
Recent Basin Sediment	15	1.73	0.15	0.88	0.02	0.18	0.08
Alluvium - Clay	9	0.65	0.41	0.50	0.02	0.03	0.03
Missoula Flood Deposits – Silt	24	0.74	0.14	0.43	0.05	0.01	0.03

Table 3-12
Recommended Design Compression Index by ESU

ESU	Design recommendation	
	Compression index (Cc)	Compression index (Cr)
Recent Basin Sediment – Swan Island	0.9	0.08
Alluvium - Clay	0.5	0.03
Missoula Flood Deposits – Silt	0.4	0.03

3.7 PERMEABILTY

Permeability been used to determine the coefficient of consolidation for time-dependent settlement analysis. Permeability and coefficient of consolidation is a difficult parameter to estimate for design use as the in situ stratigraphy can include varied layers and lenses that influence drainage. Therefore, for the purposes of design the following ranges are recommended for global permeability values in time dependent settlement analysis.

- 0 – 10 ft k = 0.103 ft/year

- 10 – 20 ft k = 1.03 ft/year
- > 20 ft k = 10.3 ft/year

These values are estimations based soil descriptions and published literature.

3.8 PRECONSOLIDATION PRESSURE

The subsurface soils within the Project area are characterized by a sequence of Holocene-age alluvial and marine deposits. The underlying soils are not considered to have experienced significant historical consolidation loads beyond those associated with natural sedimentation, anthropogenic fills, and potential minor overburden from historical dredge spoil or surficial structures.

Within the basin, historical data and bathymetric records indicate that the site has undergone periodic dredging, likely removing up to 15 to 20 feet of overburden. This past removal of overburden suggests that the current vertical effective stress may under-represent the peak historical loading conditions, and therefore some overconsolidation may be present in the upper layers due to unloading. For the underlying materials within the basin it is estimated the overconsolidation ratio (OCR) will range between 1.0 and 2.0 in the upper 20 to 30 feet, consistent with slightly to moderately overconsolidated behavior due to historical unloading. Below these depths, soils generally exhibit normally consolidated behavior with OCRs approaching 1.0.

For materials on land the ESUs are considered to be normally consolidated soils due to their depositional and erosional history.

3.9 LATERAL EARTH PRESSURE COEFFICIENT

In situ earth pressure, K_0, provides a means of quantifying the magnitude of horizontal stress in undisturbed ground.

Jaky (1944) presented the following relationship for normally consolidated soils on level ground.

$$K_0 = 1 - \sin\varphi'$$

Using the drained strength parameters reported in Section 3.3, the following values are recommended for design.

Table 3-13
Earth Pressure Coefficients

ESU	φ'_{peak} (°)	K_0 range	K_0 value
Artificial Fill	32 – 35	0.43 – 0.47	0.45
Recent Basin Sediment – Mocks Bottom	32 – 34	0.44 – 0.47	0.45
Recent Basin Sediment – Swan Island	31 – 33	0.46 – 0.48	0.47
Alluvium – Sand (EL ≥ -10 ft)	32 – 34	0.44 – 0.47	0.45
Alluvium – Sand (EL < -10 ft)	34 – 36	0.41 – 0.47	0.45
Alluvium – Clay	24 – 26	0.56 – 0.59	0.58

ESU	φ'_{peak} (°)	K_0 range	K_0 value
Missoula Flood Deposits – Silt	31 – 33	0.46 – 0.48	0.47
Missoula Flood Deposits – Sand (EL ≥ -80 ft)	34 – 36	0.41 – 0.47	0.45
Missoula Flood Deposits – Sand (EL < -80 ft)	36 – 38	0.38 – 0.41	0.40

3.10 SMALL STRAIN SHEAR MODULUS

The small strain shear modulus (G_0) was evaluated for each project ESU, and for upland and in-water conditions utilizing the following relationship.

$$G_0 = \frac{\gamma}{g} V_s^2$$

Where ϒ is bulk unit weight in pounds per cubic foot, g is the gravitational constant (32.17 ft/s^2), and V_s is shear wave velo city. The bulk unit weight used to derive G_0 is provided in Table 3 14. The bulk unit weight in Table 3 14 is simplified from Table 3 5 due to the low quantity of Recent Basin Sediment V_s data, and V_s profile derivation method (function of depth and overburden).

Table 3-14
Bulk Unit Weight Data by ESU for G_0 Derivation

ESU	Recommended ϒ (pcf)
Artificial Fill	110
Recent Basin Sediment	100
Alluvium – Sand	117.5
Alluvium - Clay	105
Missoula Flood Deposits – Silt	110
Missoula Flood Deposits – Sand	120

Shear wave velocity profiles for each ESU were developed using linear and polynomial regression in accordance with Sykora (1987).

$$V_s = a \times D + b$$

$$V_s = m \times D^s$$

Where D is depth below ground surface in feet, and a, b, m, and s are coefficients determined by curve fitting to field measured V_s data from downhole P- and S-wave logging and seismic cone penetration testing.

Shear wave velocity profile equations are presented in Table 3 15. Upper and lower bound depths included in Table 3 15 represent the maximum and minimum depths an ESU was encountered in the geotechnical investigation. The V_s profile equations should not be extrapolated beyond

boundary conditions. In some cases two sets of values are presented for both Alluvium – Clay and Missoula Flood Deposits – Silt in the upland condition. In these cases the shear wave velocity profiles varies with depth which warrants the use of separate regression equations where material behavior, consistency or data trends differ. The transition depths reflect changes observed in the dataset.

Table 3-15
Shear Wave Velocity Profile Equations

ESU	Location	Depth Upper Bound	Depth Lower Bound	V_s Eq.	Coeff. m or a	Coeff. s or b
Artificial Fill	Upland	0	33	m*Ds	697.71	0.00305
Artificial Fill	In Water	N/A	N/A	N/A	N/A	N/A
Recent Basin Sediment	Upland	26	68	m*Ds	209.49	0.256
Recent Basin Sediment	In Water	0	37	m*Ds	45.61	0.403
Alluvium – Sand	Upland	12	86.5	m*Ds	576.08	0
Alluvium - Sand	In Water	0	34.5	m*Ds	985.258	0
Alluvium - Clay	Upland	25	65	m*Ds	352.717	0.0864
Alluvium - Clay	Upland	65	81	a*D + b	13.2	-352.2
Alluvium - Clay	In Water	6	33	a*D + b	13.2	-38
Missoula Flood Deposits - Silt	Upland	25	75	m*Ds	98.641	0.433
Missoula Flood Deposits - Silt	Upland	75	121.5	m*Ds	250	0.217
Missoula Flood Deposits - Silt	In Water	0	80	m*Ds	220.532	0.256
Missoula Flood Deposits - Sand	Upland	53	121.5	m*Ds	147.4	0.343
Missoula Flood Deposits - Sand	In Water	6	95.5	m*Ds	518.46	0.052

3.11 POISSON'S RATIO

For the SIB Project Area, Poisson's ratio values were estimated based on typical values for similar soil types, laboratory test data where available, and published literature (e.g., NAVFAC DM 7.1, 2022).

The values are summarized by ESU in Table 3-16.

Table 3-16
Recommended Poisson's Ratio

ESU	Recommended Poisson's Ratio (v)
Artificial Fill	0.30
Recent Basin Sediment – Mocks Bottom	0.35
Recent Basin Sediment – Swan Island	0.45
Alluvium - Sand	0.25
Alluvium - Clay	0.40
Missoula Flood Deposits – Silt	0.40
Missoula Flood Deposits - Sand	0.30

These values are consistent with typical ranges:

- Sands and gravels: 0.25 – 0.35
- Silts and clays: 0.30 – 0.50

ATTACHMENT B
SEISMIC ASSESSMENT

1.0 INTRODUCTION

This attachment to the 90% Geotechnical Design Technical Memorandum (GDTM) presents analysis output files of the earthquake-induced soil liquefaction analysis conducted as part of the geotechnical evaluation of the Swan Island Basin (SIB) Project Area, located within the Portland Harbor Superfund Site in Portland, Multnomah County, Oregon.

The Remedial Design (RD), along with estimates of seismic hazards and ground motion parameters, and evaluations of liquefaction susceptibility and its consequences at the project site are presented in the main body of the 90% GDTM. The estimated seismic performance of riverbank slopes under both existing and post-remediation conditions are presented in Attachment C. Liquefaction triggering and consequences assessments for new marine structures are presented in Attachment D.

1.1 LIQUEFACTION TRIGGERING ANALYSES OUTPUT FILES

Liquefaction analysis reports that include the input parameters and analysis results for each cone penetration test and standard penetration test location analyzed were generated in CLiq and are provided as part of this Attachment.

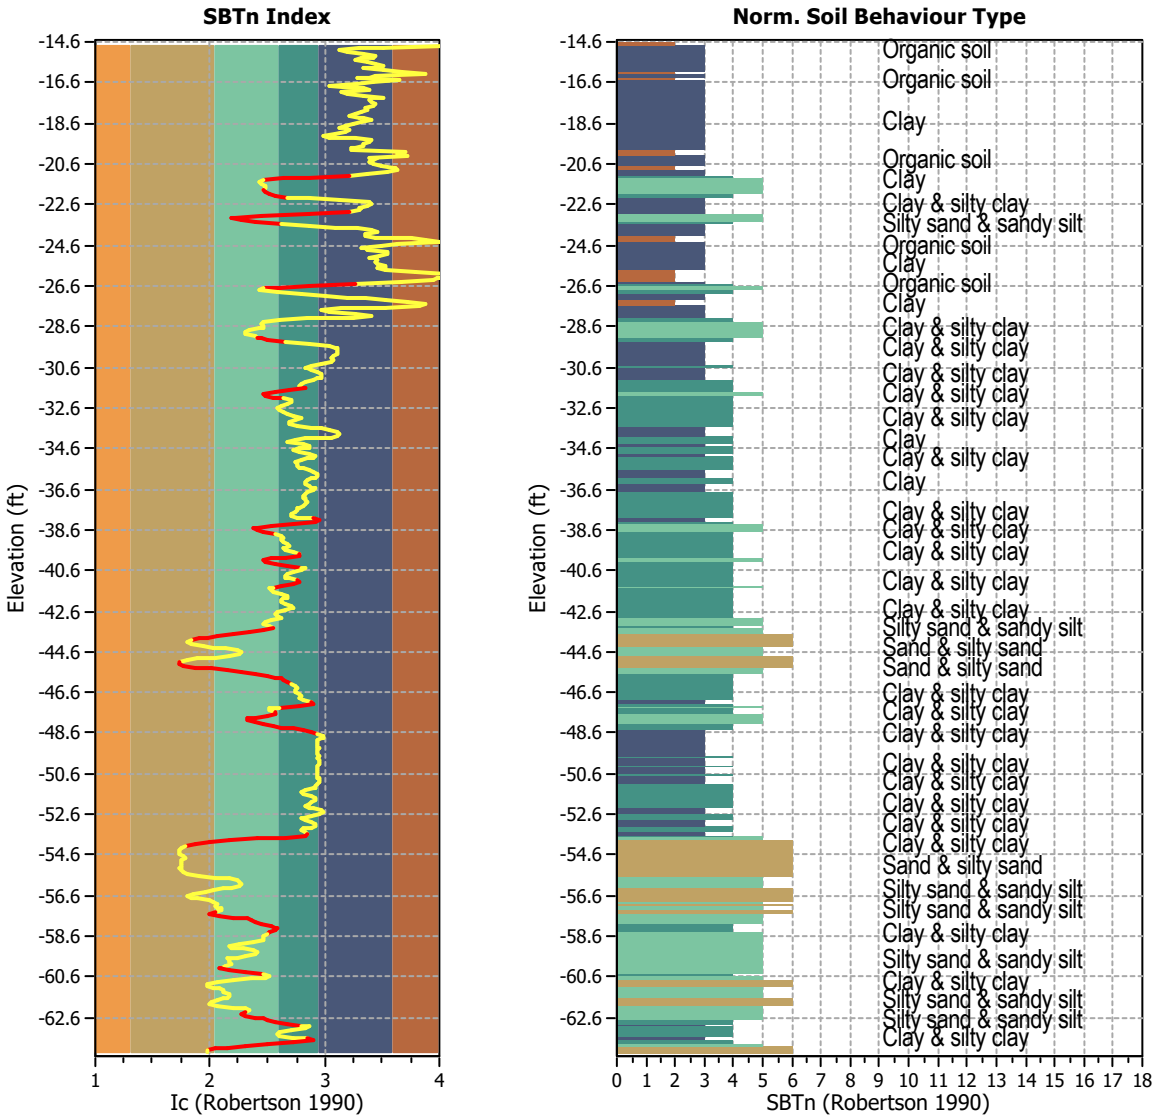
TRANSITION LAYER DETECTION ALGORITHM REPORT
Summary Details & Plots

Short description

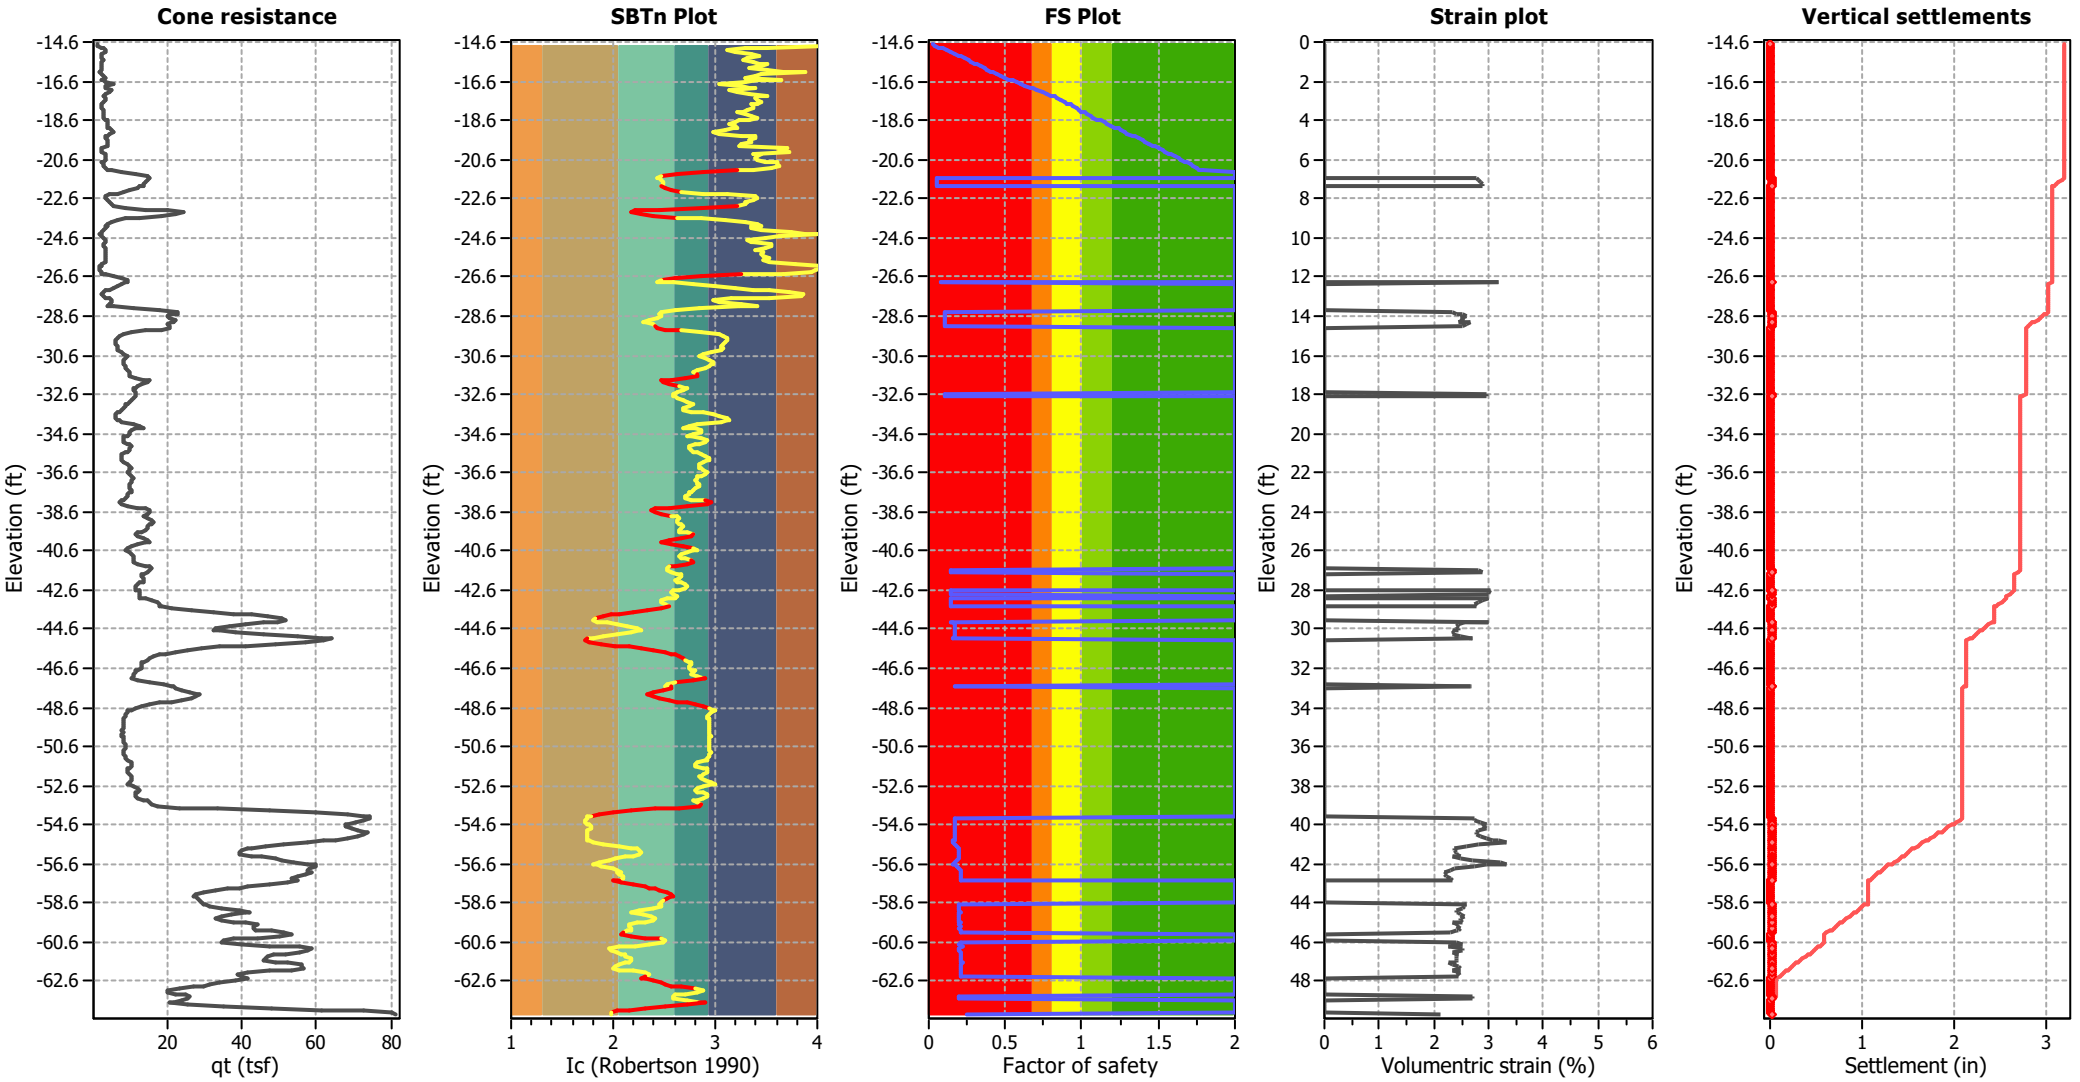
The software will delete data when the cone is in transition from either clay to sand or vise-versa. To do this the software requires a range of I_c values over which the transition will be defined (typically somewhere between $1.80 < I_c < 3.0$) and a rate of change of I_c. Transitions typically occur when the rate of change of I_c is fast (i.e. delta I_c is small).

The SBT_n plot below, displays in red the detected transition layers based on the parameters listed below the graphs.



Transition layer algorithm properties		General statistics	
I_c minimum check value:	1.70	Total points in CPT file:	606
I_c maximum check value:	3.00	Total points excluded:	143
I_c change ratio value:	0.0250	Exclusion percentage:	23.60%
Minimum number of points in layer:	4	Number of layers detected:	24

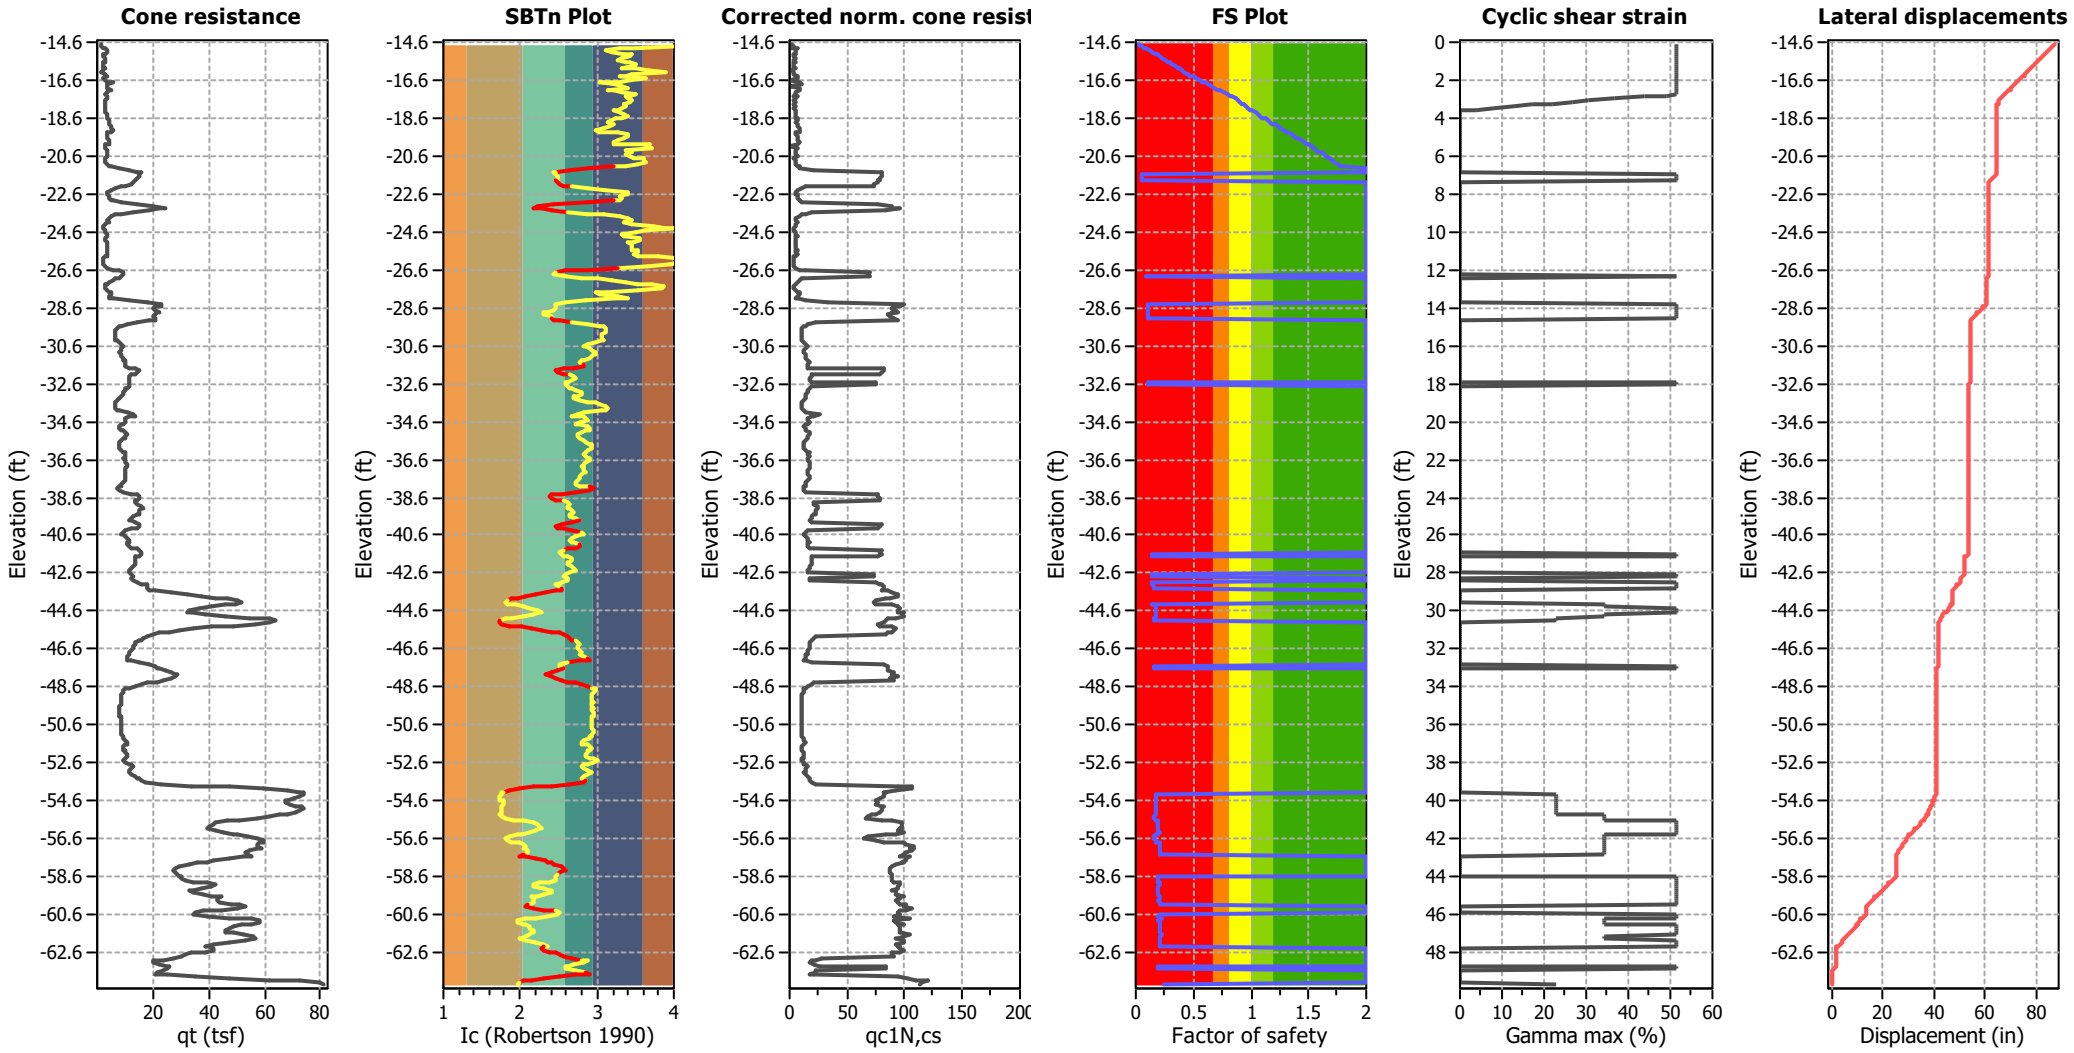
Estimation of post-earthquake settlements



Abbreviations

q_t:	Total cone resistance (cone resistance q_c corrected for pore water effects)
I_c:	Soil Behaviour Type Index
FS:	Calculated Factor of Safety against liquefaction
Volumentric strain:	Post-liquefaction volumentric strain

Estimation of post-earthquake lateral Displacements



Abbreviations

q_t: Total cone resistance (cone resistance q_c corrected for pore water effects)
I_c: Soil Behaviour Type Index
$q_{c1N,cs}$: Equivalent clean sand normalized CPT total cone resistance
F.S.: Factor of safety
γ_{max}: Maximum cyclic shear strain
LDI: Lateral displacement index

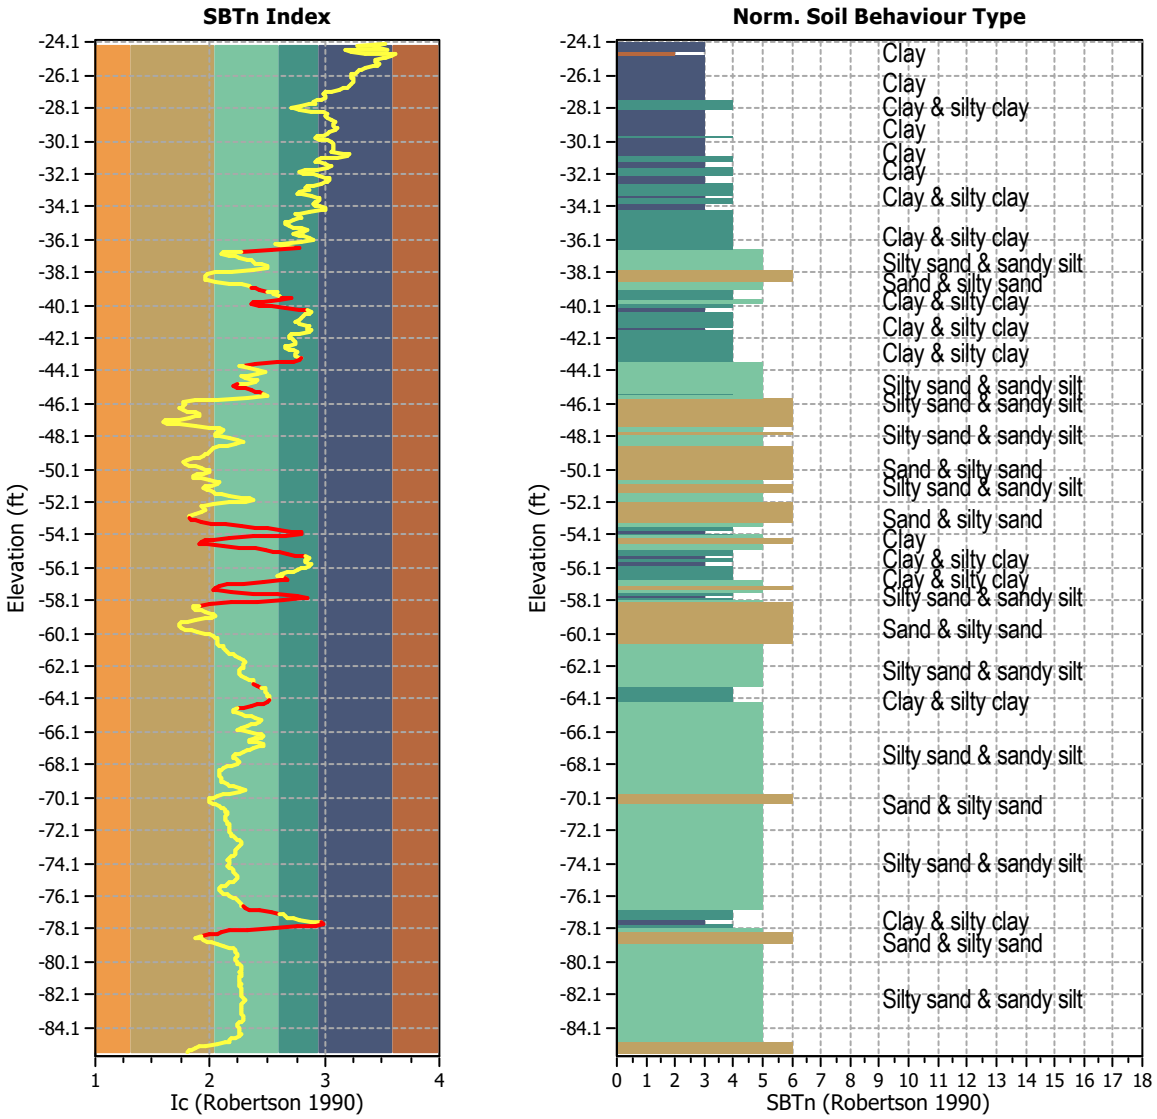
TRANSITION LAYER DETECTION ALGORITHM REPORT
Summary Details & Plots

Short description

The software will delete data when the cone is in transition from either clay to sand or vise-versa. To do this the software requires a range of I_c values over which the transition will be defined (typically somewhere between $1.80 < I_c < 3.0$) and a rate of change of I_c. Transitions typically occur when the rate of change of I_c is fast (i.e. delta I_c is small).

The SBT_n plot below, displays in red the detected transition layers based on the parameters listed below the graphs.



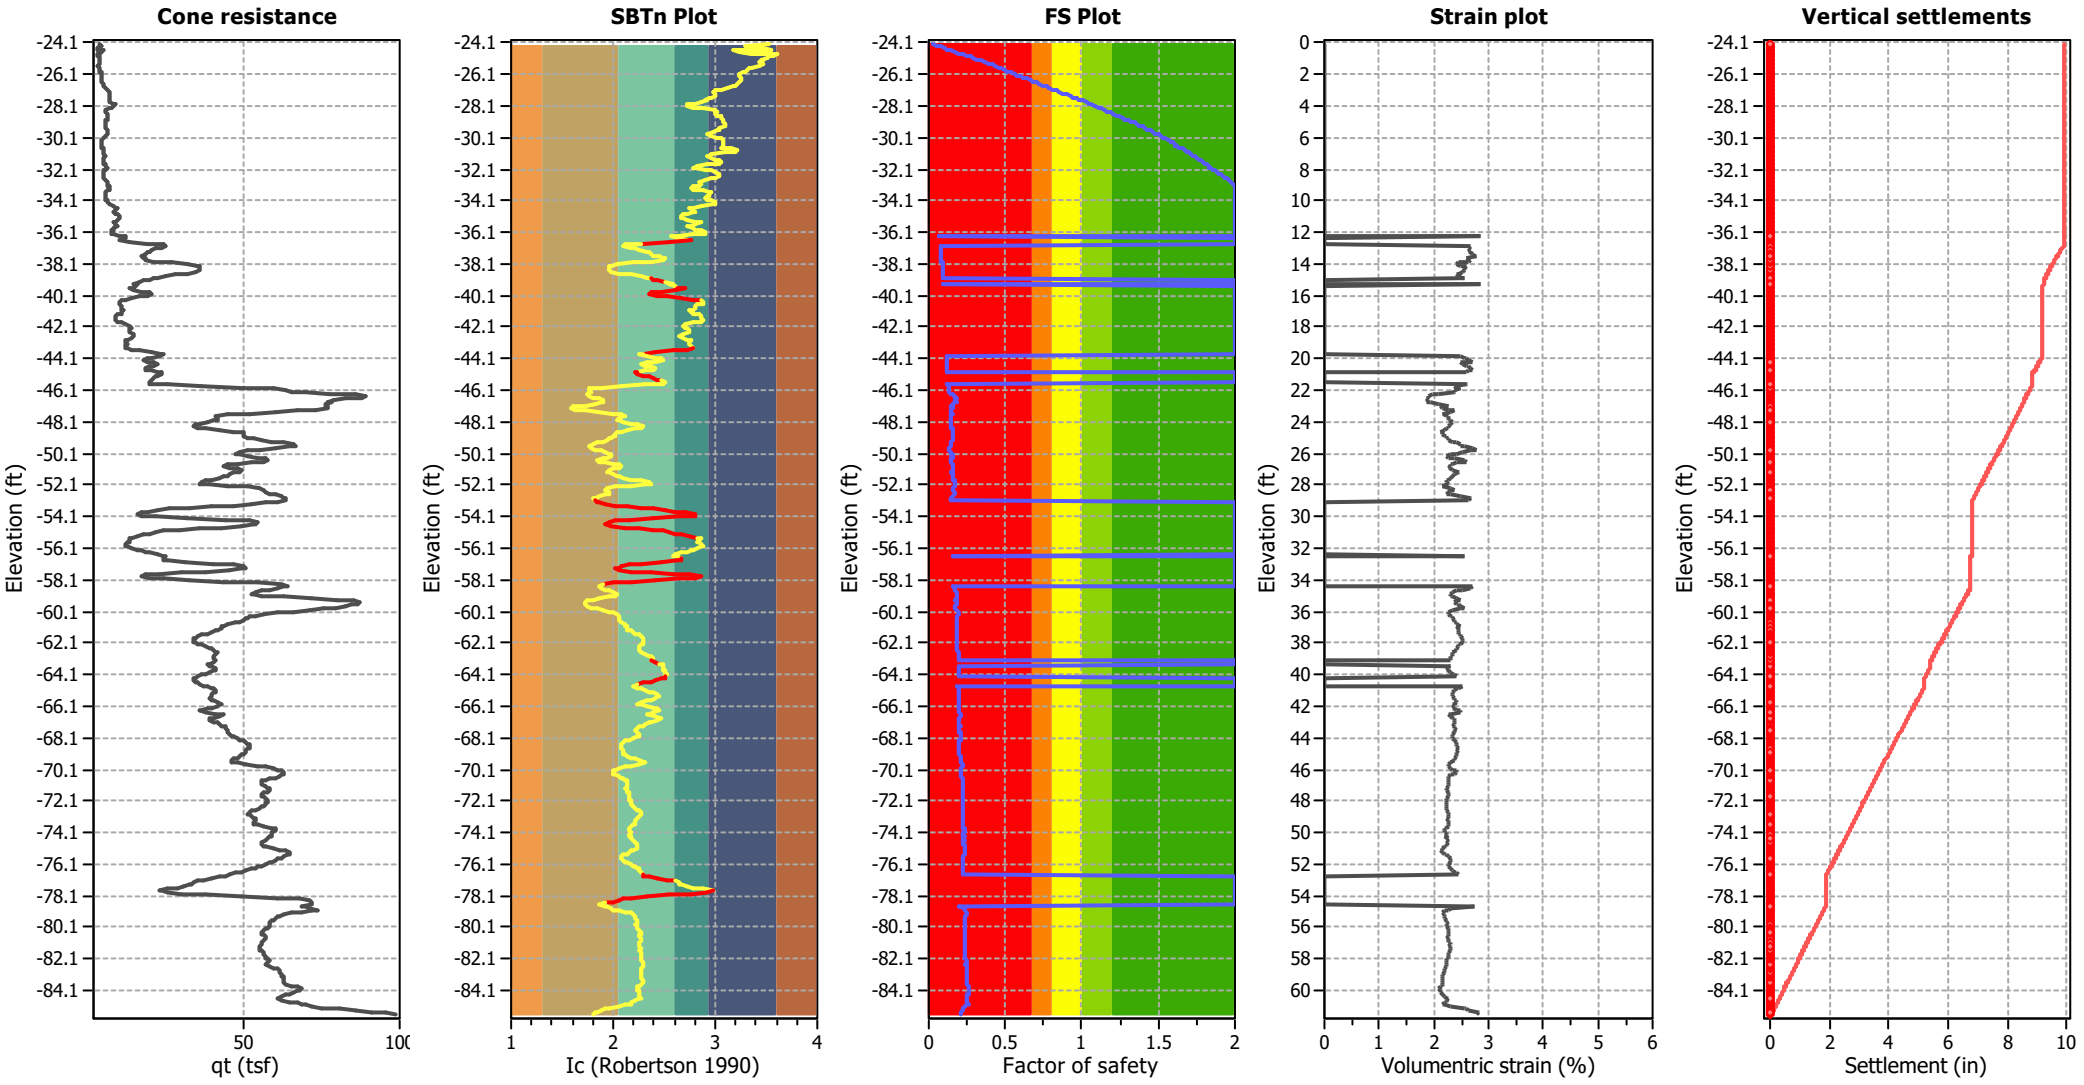
Transition layer algorithm properties

I_c minimum check value:	1.70
I_c maximum check value:	3.00
I_c change ratio value:	0.0250
Minimum number of points in layer:	4

General statistics

Total points in CPT file:	750
Total points excluded:	114
Exclusion percentage:	15.20%
Number of layers detected:	16

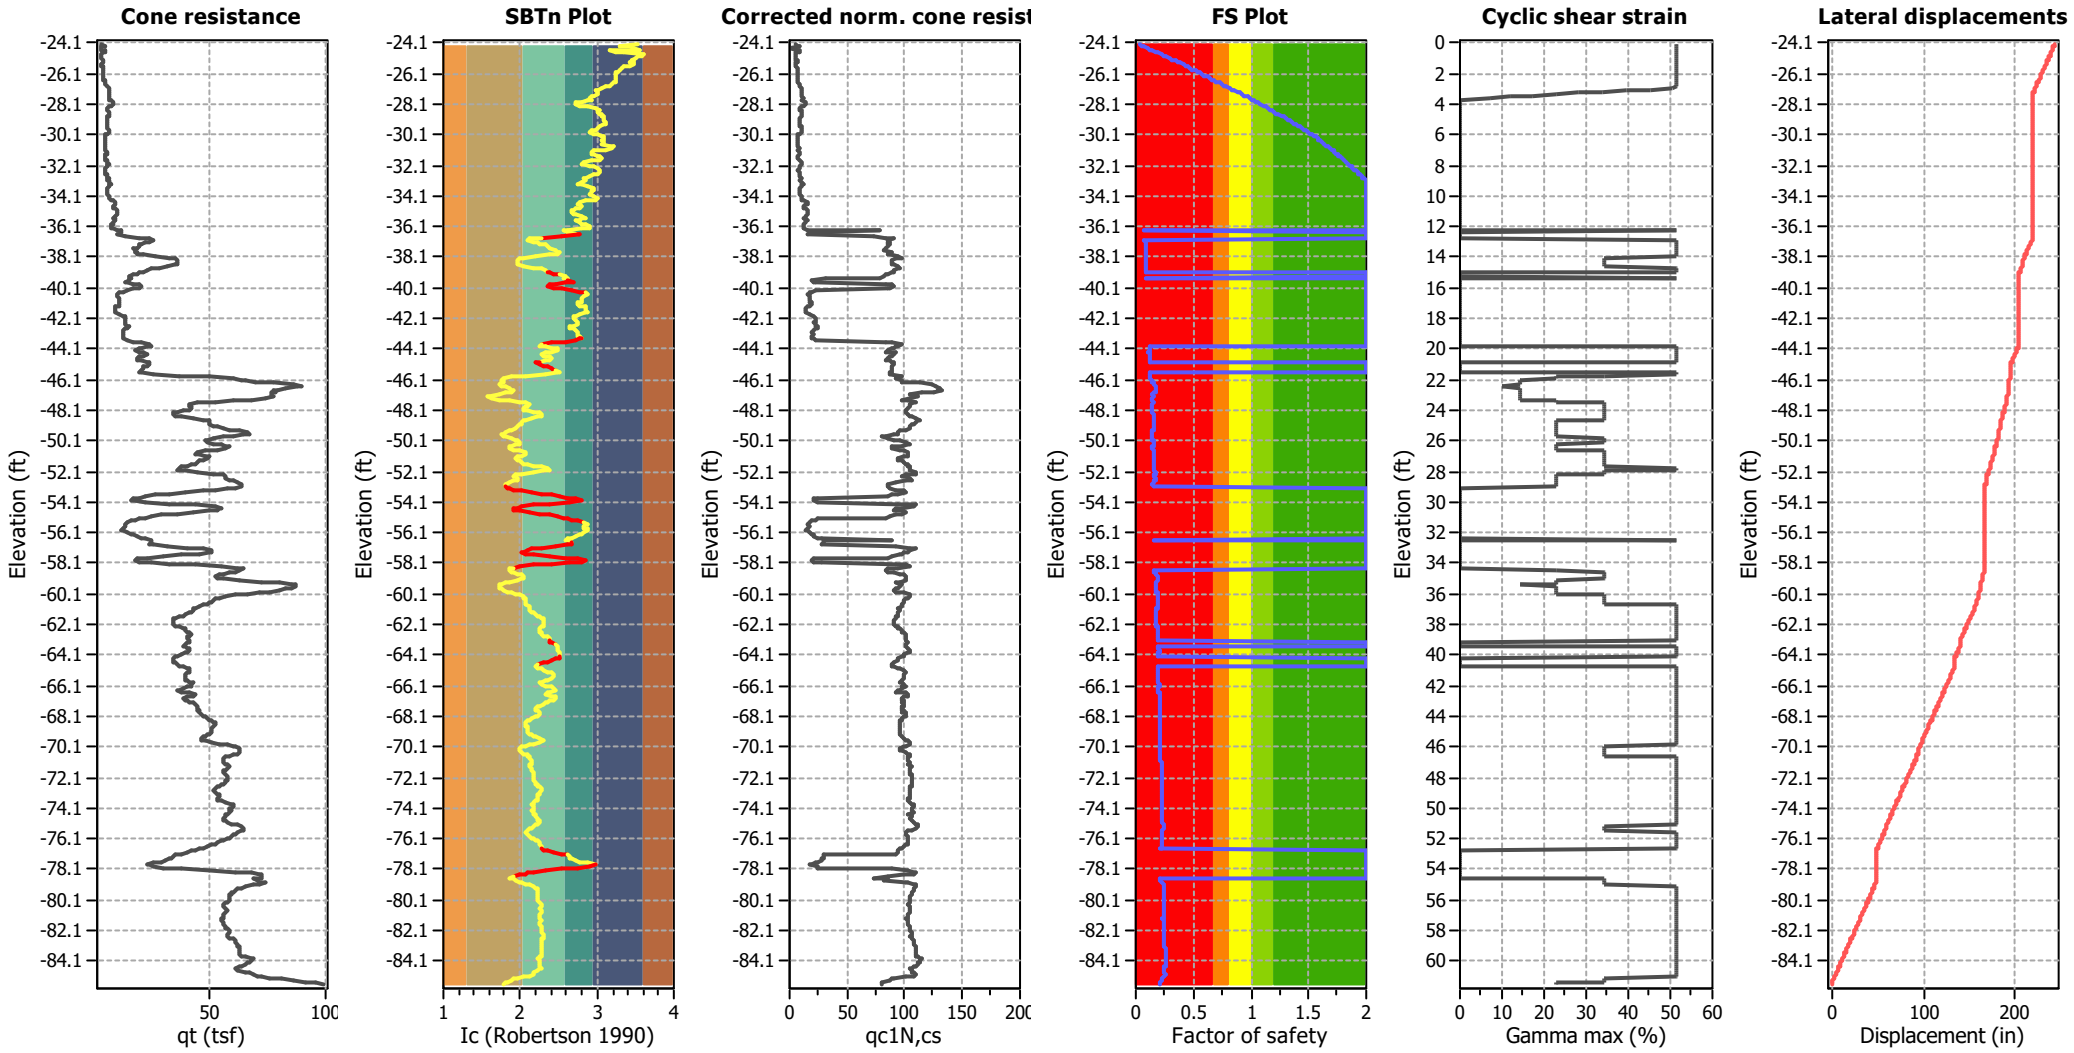
Estimation of post-earthquake settlements



Abbreviations

q_t:	Total cone resistance (cone resistance q_c corrected for pore water effects)
I_c:	Soil Behaviour Type Index
FS:	Calculated Factor of Safety against liquefaction
Volumentric strain:	Post-liquefaction volumentric strain

Estimation of post-earthquake lateral Displacements



Abbreviations

q_t: Total cone resistance (cone resistance q_c corrected for pore water effects)
I_c: Soil Behaviour Type Index
$q_{c1N,cs}$: Equivalent clean sand normalized CPT total cone resistance
F.S.: Factor of safety
γ_{max}: Maximum cyclic shear strain
LDI: Lateral displacement index

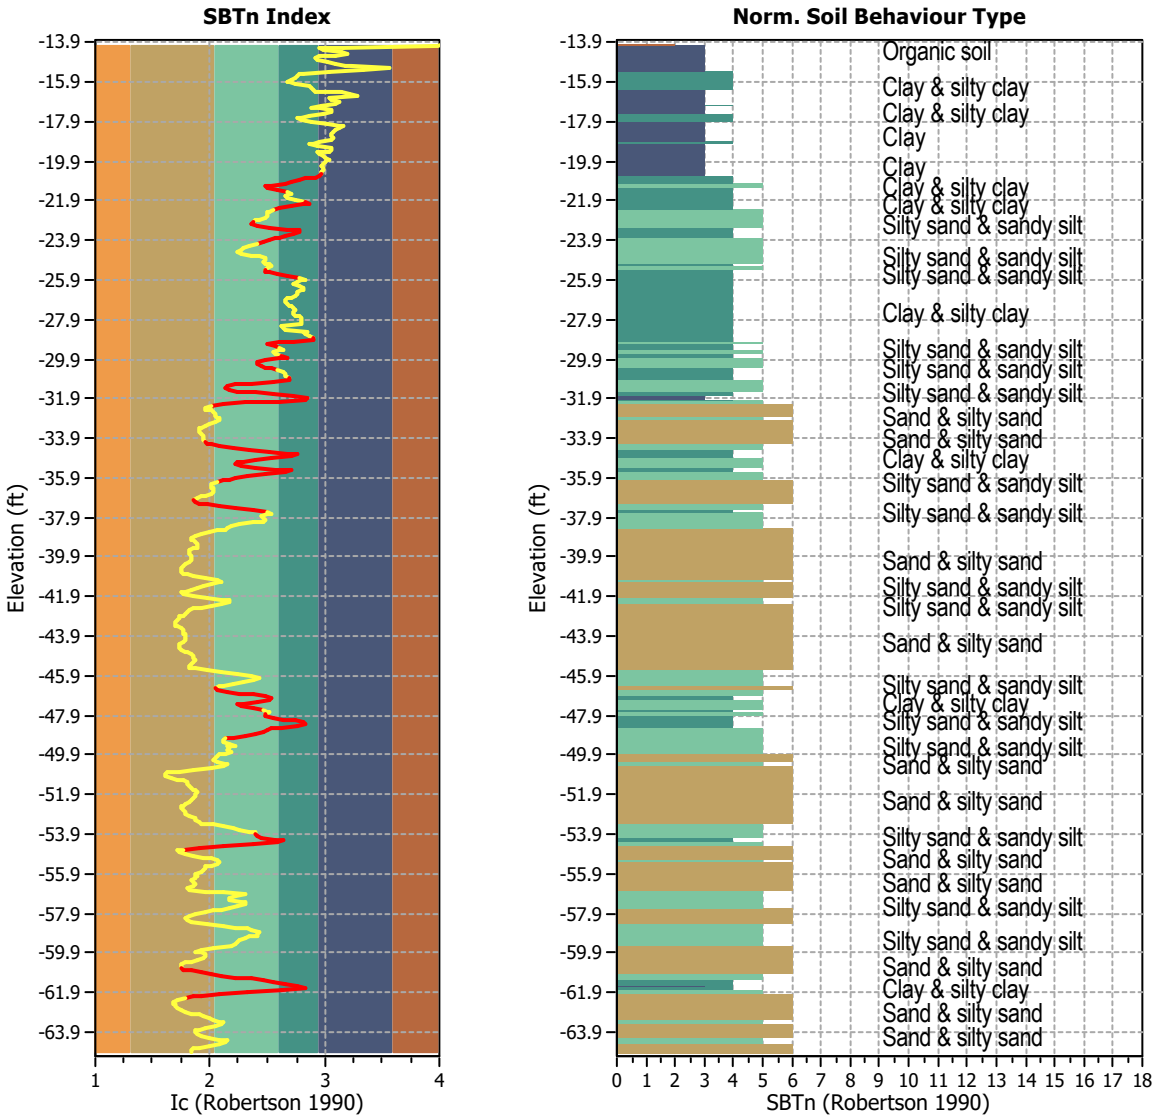
TRANSITION LAYER DETECTION ALGORITHM REPORT
Summary Details & Plots

Short description

The software will delete data when the cone is in transition from either clay to sand or vise-versa. To do this the software requires a range of I_c values over which the transition will be defined (typically somewhere between $1.80 < I_c < 3.0$) and a rate of change of I_c. Transitions typically occur when the rate of change of I_c is fast (i.e. delta I_c is small).

The SBT_n plot below, displays in red the detected transition layers based on the parameters listed below the graphs.



Transition layer algorithm properties	
I_c minimum check value:	1.70
I_c maximum check value:	3.00
I_c change ratio value:	0.0250
Minimum number of points in layer:	4

General statistics	
Total points in CPT file:	610
Total points excluded:	37
Exclusion percentage:	6.07%
Number of layers detected:	5

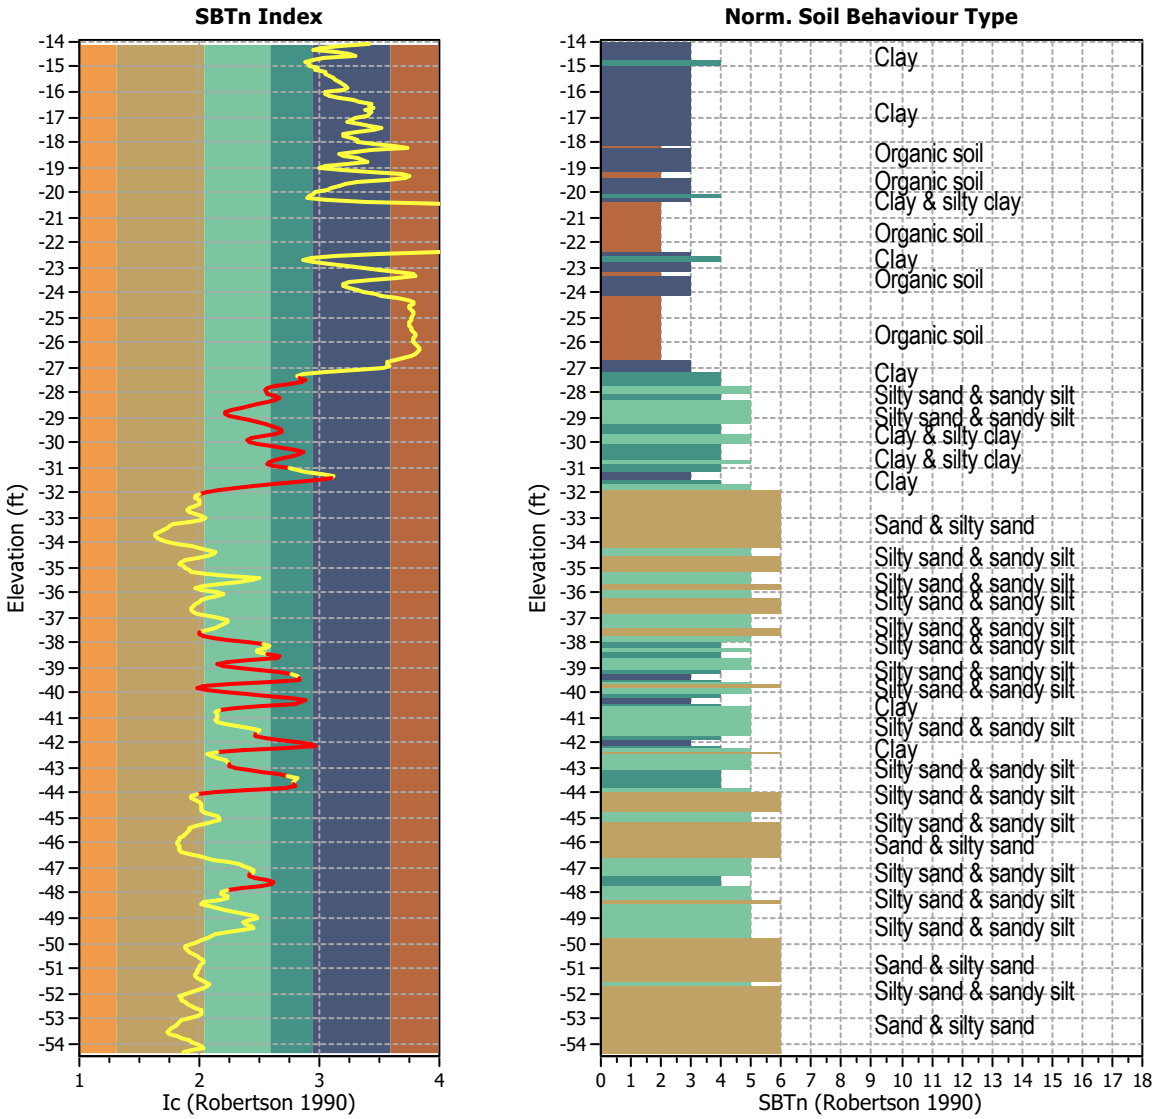
TRANSITION LAYER DETECTION ALGORITHM REPORT
Summary Details & Plots

Short description

The software will delete data when the cone is in transition from either clay to sand or vise-versa. To do this the software requires a range of I_c values over which the transition will be defined (typically somewhere between $1.80 < I_c < 3.0$) and a rate of change of I_c. Transitions typically occur when the rate of change of I_c is fast (i.e. delta I_c is small).

The SBT_n plot below, displays in red the detected transition layers based on the parameters listed below the graphs.



Transition layer algorithm properties		General statistics	
I_c minimum check value:	1.70	Total points in CPT file:	732
I_c maximum check value:	3.00	Total points excluded:	126
I_c change ratio value:	0.0250	Exclusion percentage:	17.21%
Minimum number of points in layer:	4	Number of layers detected:	20

Estimation of post-earthquake settlements

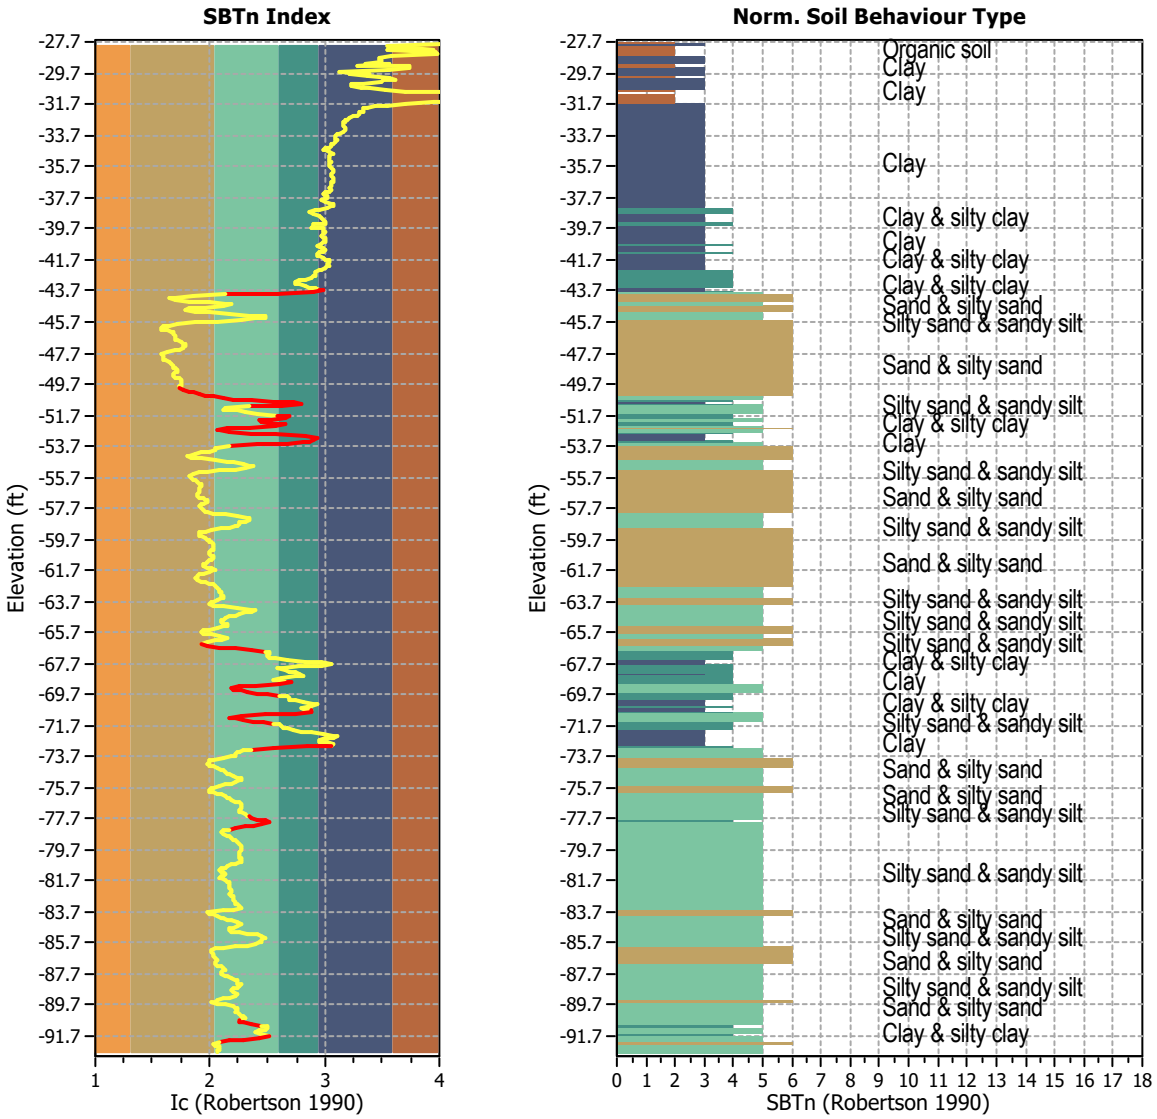
TRANSITION LAYER DETECTION ALGORITHM REPORT
Summary Details & Plots

Short description

The software will delete data when the cone is in transition from either clay to sand or vise-versa. To do this the software requires a range of I_c values over which the transition will be defined (typically somewhere between $1.80 < I_c < 3.0$) and a rate of change of I_c. Transitions typically occur when the rate of change of I_c is fast (i.e. delta I_c is small).

The SBT_n plot below, displays in red the detected transition layers based on the parameters listed below the graphs.



Transition layer algorithm properties		General statistics	
I_c minimum check value:	1.70	Total points in CPT file:	696
I_c maximum check value:	3.00	Total points excluded:	65
I_c change ratio value:	0.0250	Exclusion percentage:	9.34%
Minimum number of points in layer:	4	Number of layers detected:	12

TRANSITION LAYER DETECTION ALGORITHM REPORT
Summary Details & Plots

Short description

The software will delete data when the cone is in transition from either clay to sand or vise-versa. To do this the software requires a range of I_c values over which the transition will be defined (typically somewhere between $1.80 < I_c < 3.0$) and a rate of change of I_c. Transitions typically occur when the rate of change of I_c is fast (i.e. delta I_c is small).

The SBT_n plot below, displays in red the detected transition layers based on the parameters listed below the graphs.

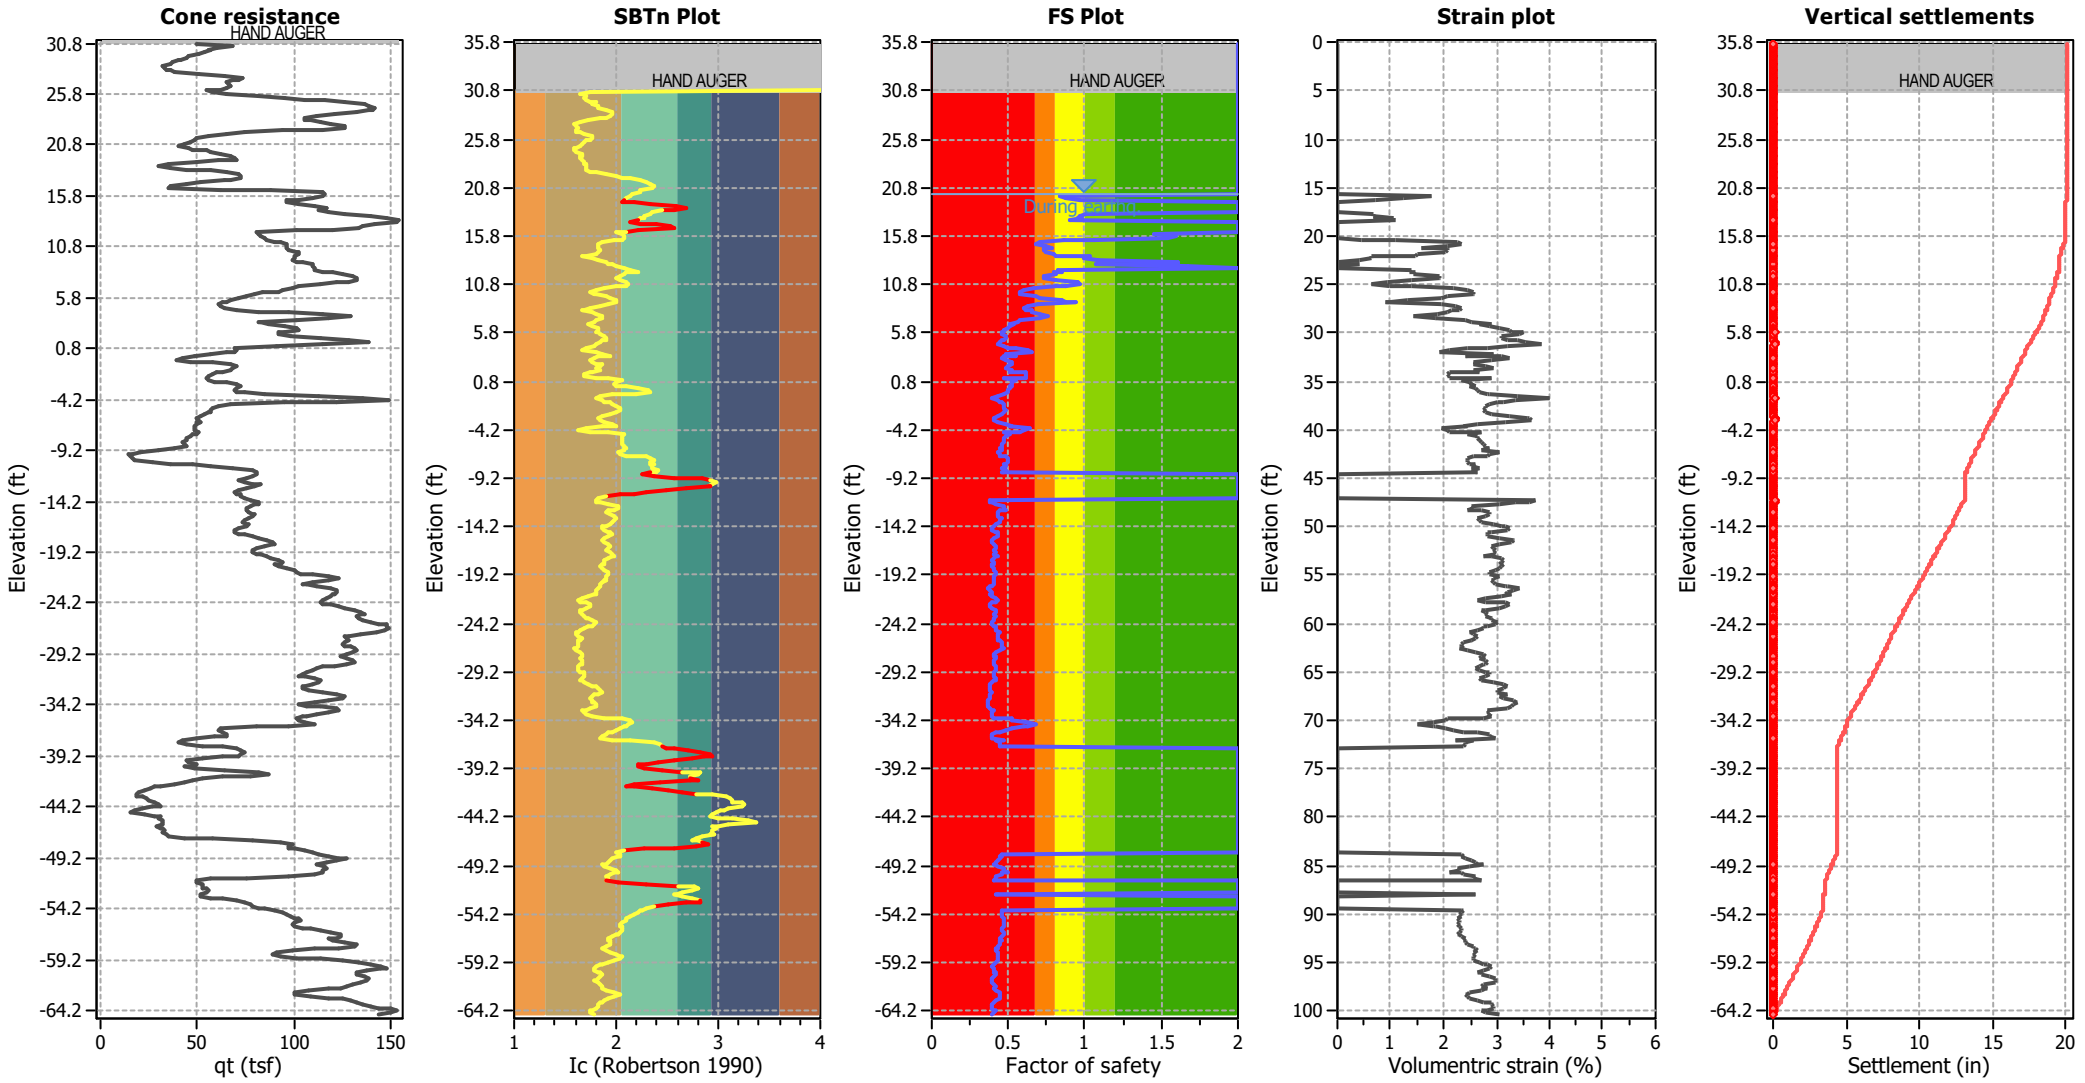
Transition layer algorithm properties	
I_c minimum check value:	1.70
I_c maximum check value:	3.00
I_c change ratio value:	0.0250
Minimum number of points in layer:	4

General statistics	
Total points in CPT file:	612
Total points excluded:	76
Exclusion percentage:	12.42%
Number of layers detected:	14

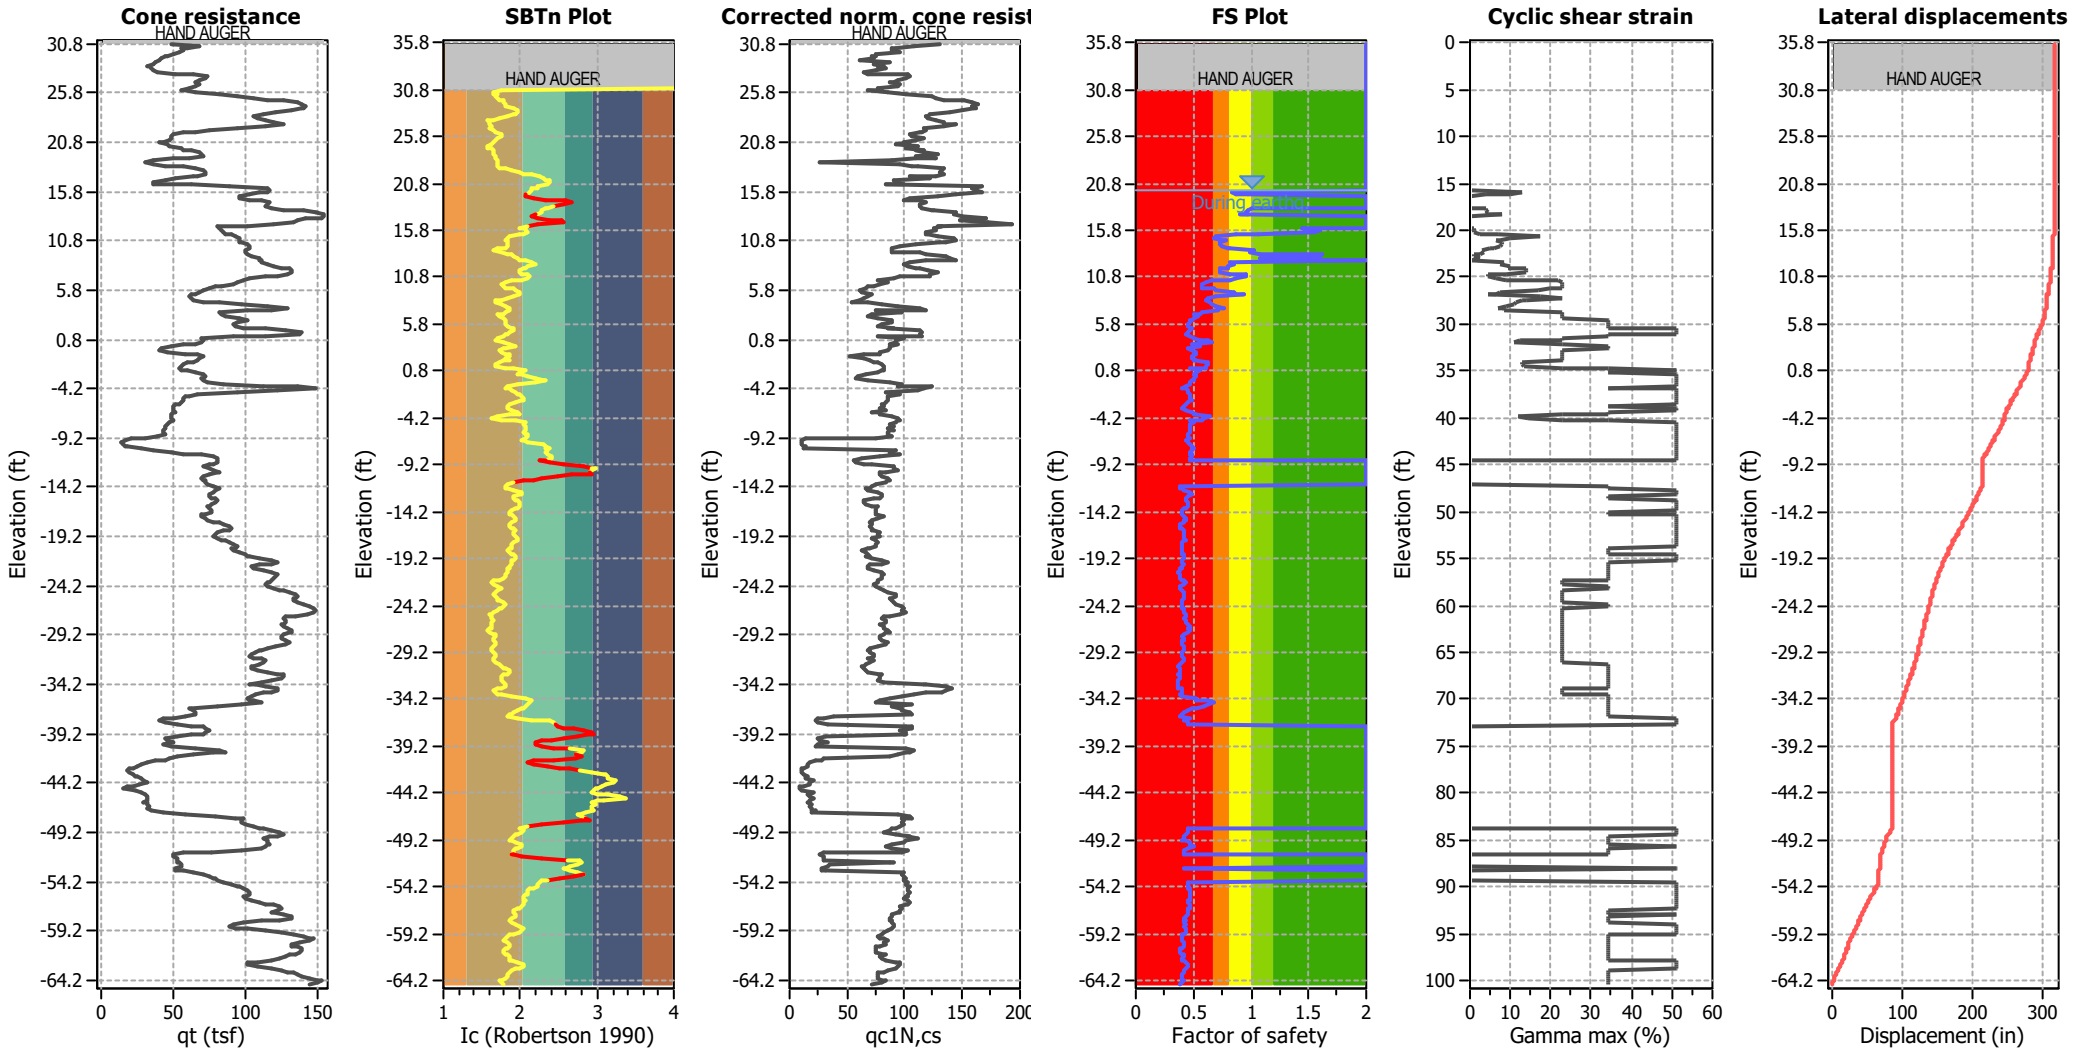
Estimation of post-earthquake settlements



Abbreviations

q_t:	Total cone resistance (cone resistance q_c corrected for pore water effects)
I_c:	Soil Behaviour Type Index
FS:	Calculated Factor of Safety against liquefaction
Volumentric strain:	Post-liquefaction volumentric strain

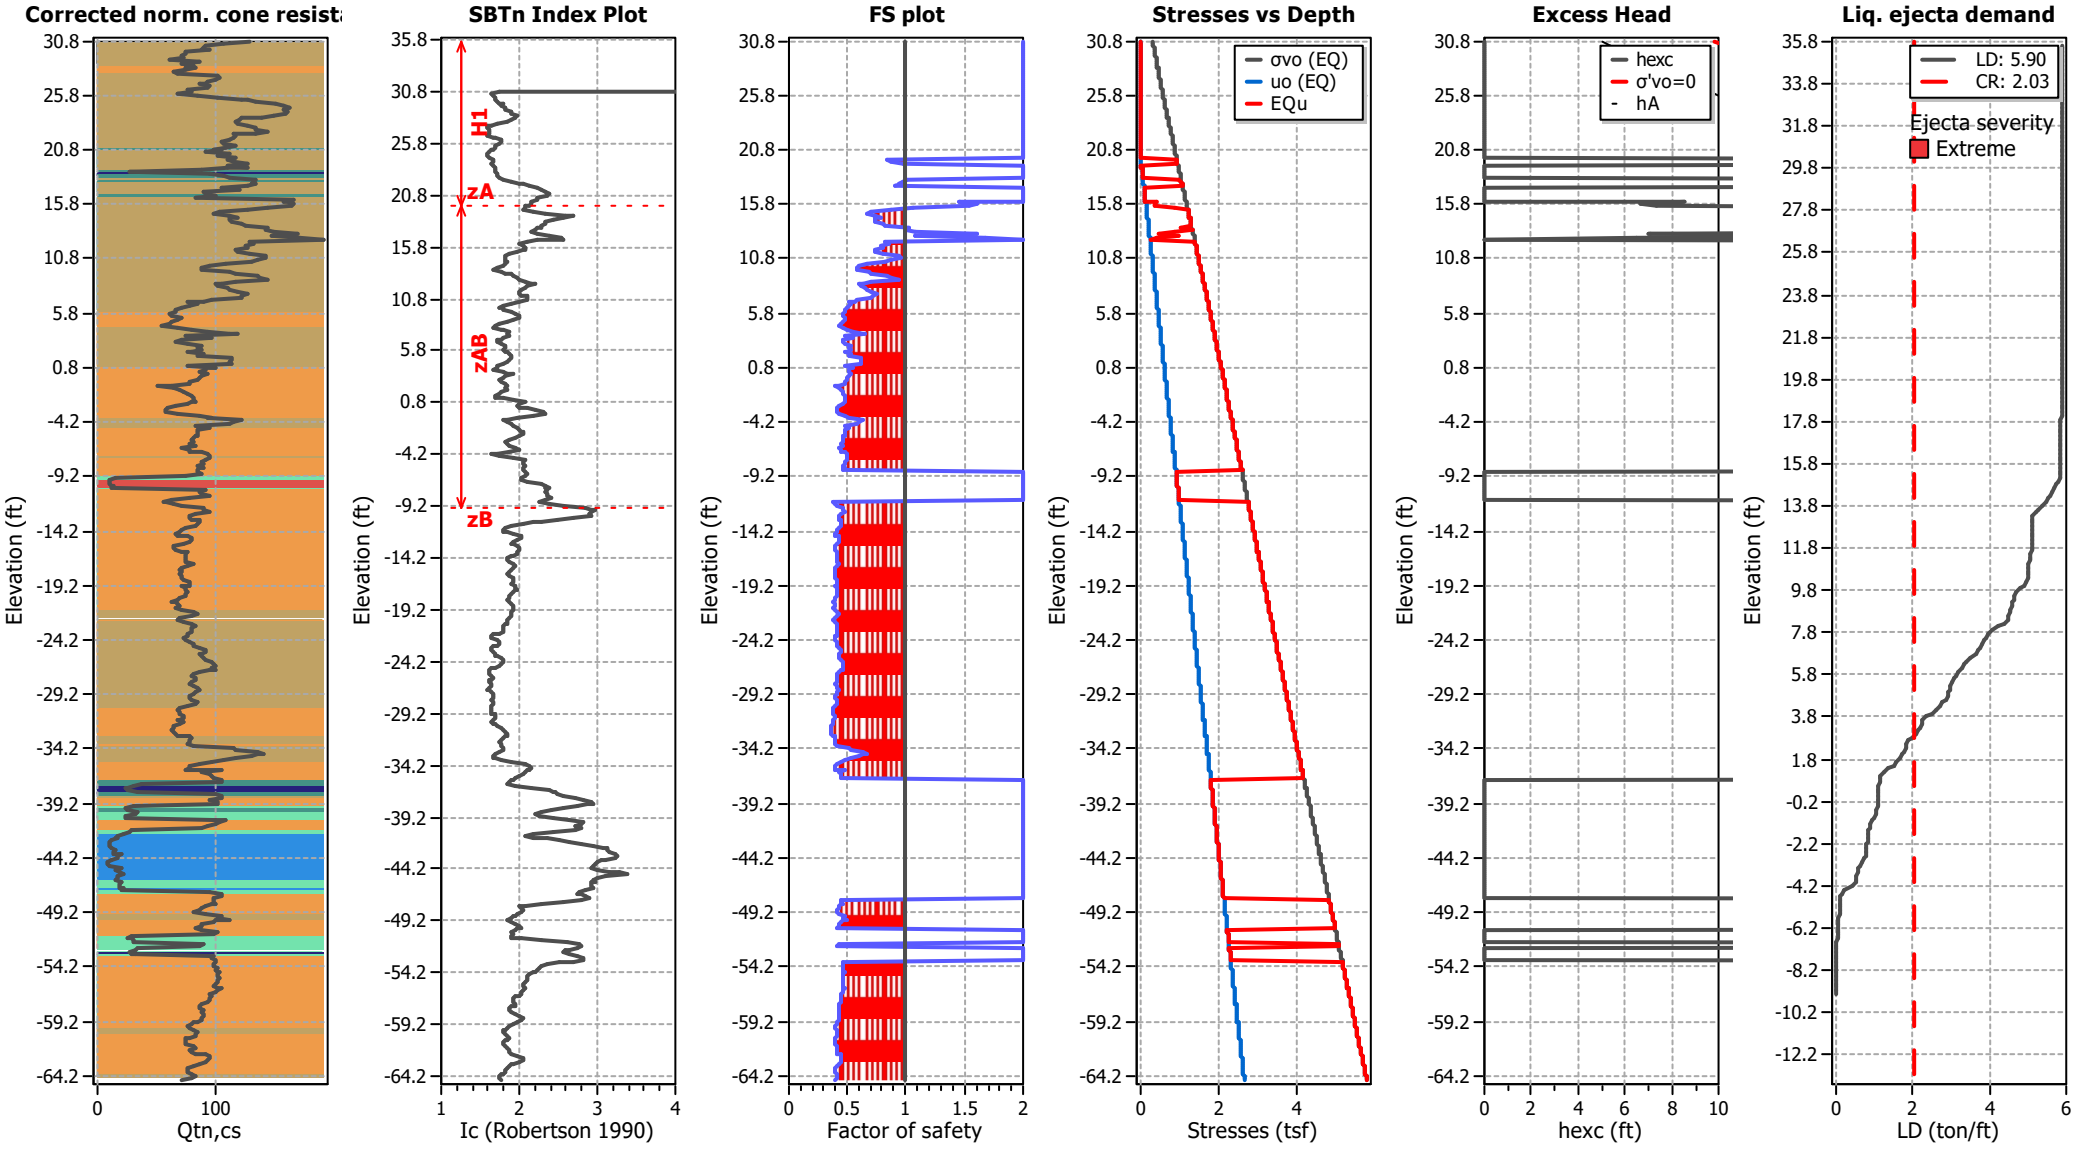
Estimation of post-earthquake lateral Displacements



Abbreviations

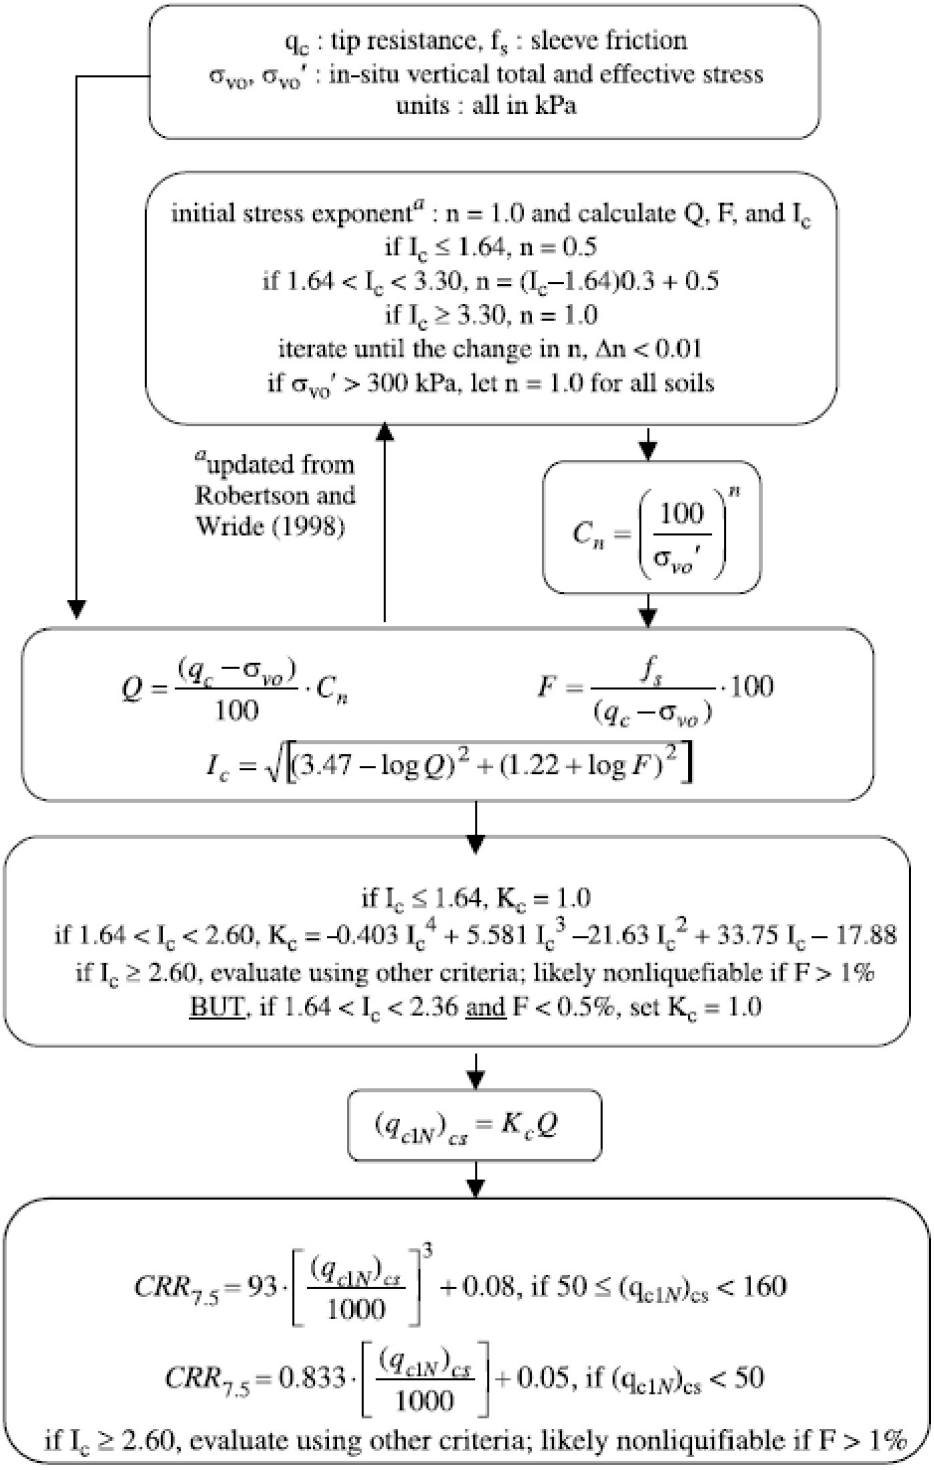
q_t: Total cone resistance (cone resistance q_c corrected for pore water effects)
I_c: Soil Behaviour Type Index
$q_{c1N,cs}$: Equivalent clean sand normalized CPT total cone resistance
F.S.: Factor of safety
γ_{max}: Maximum cyclic shear strain
LDI: Lateral displacement index

Ejecta Severity Estimation



Procedure for the evaluation of soil liquefaction resistance, NCEER (1998)

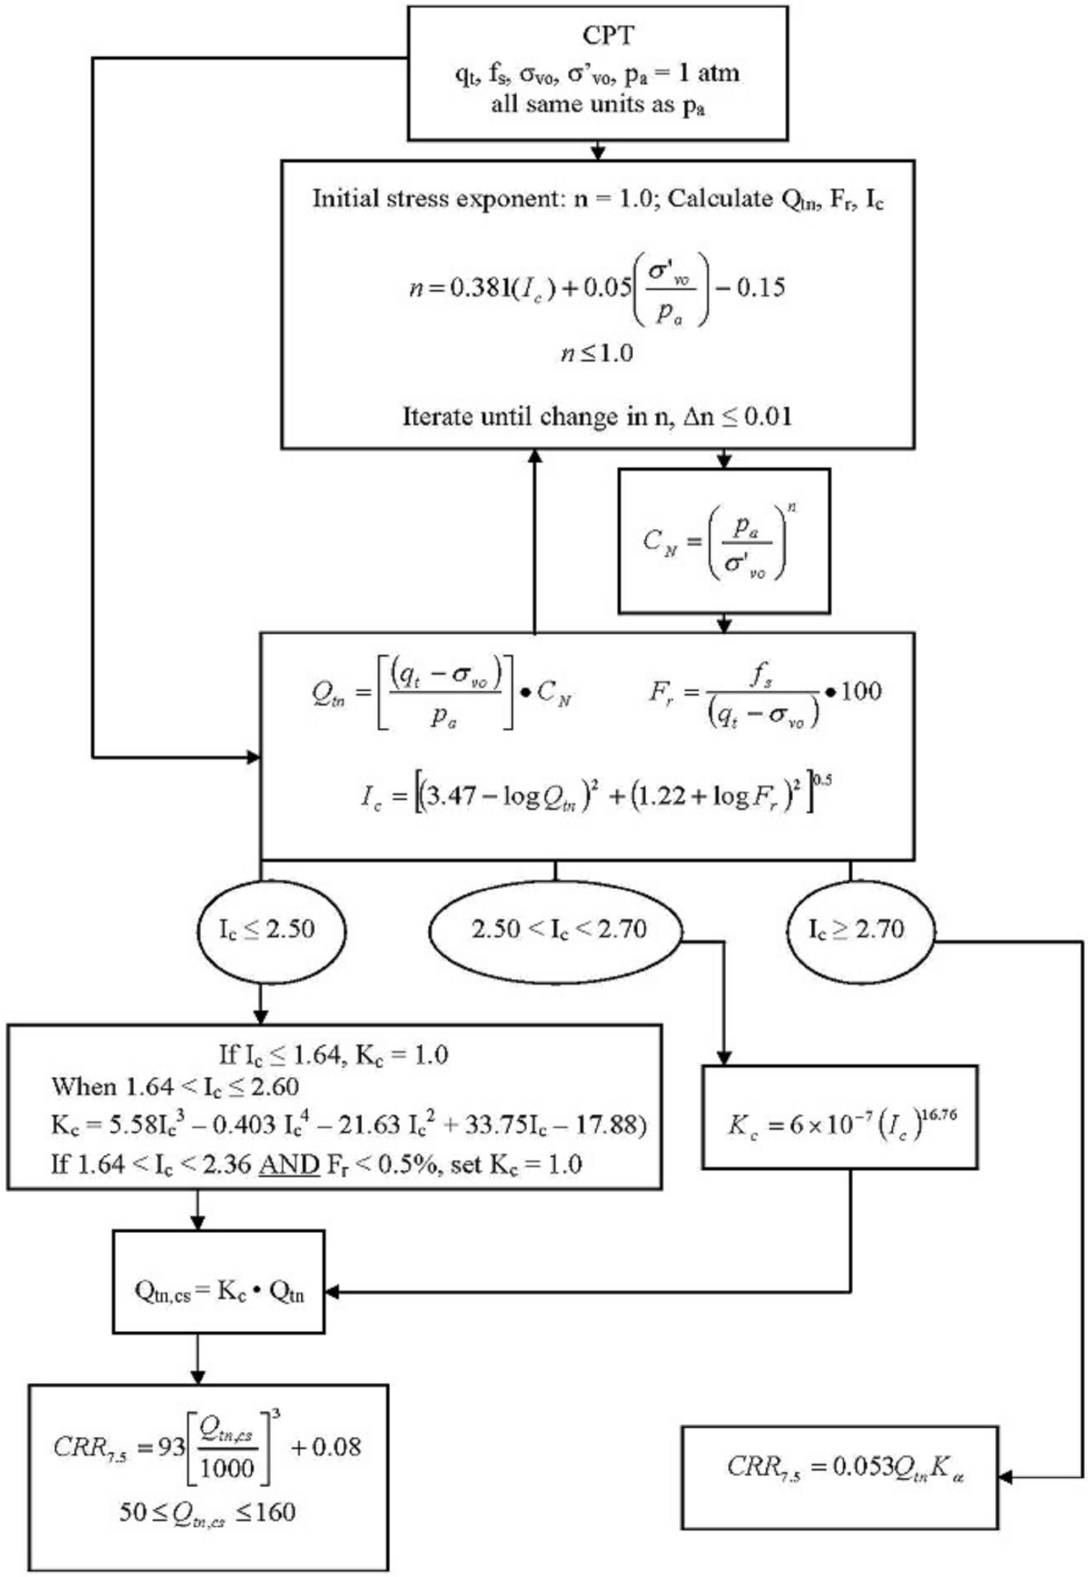
Calculation of soil resistance against liquefaction is performed according to the Robertson & Wride (1998) procedure. The procedure used in the software, slightly differs from the one originally published in NCEER-97-0022 (Proceedings of the NCEER Workshop on Evaluation of Liquefaction Resistance of Soils). The revised procedure is presented below in the form of a flowchart[1]:



[1] "Estimating liquefaction-induced ground settlements from CPT for level ground", G. Zhang, P.K. Robertson, and R.W.I. Brachman

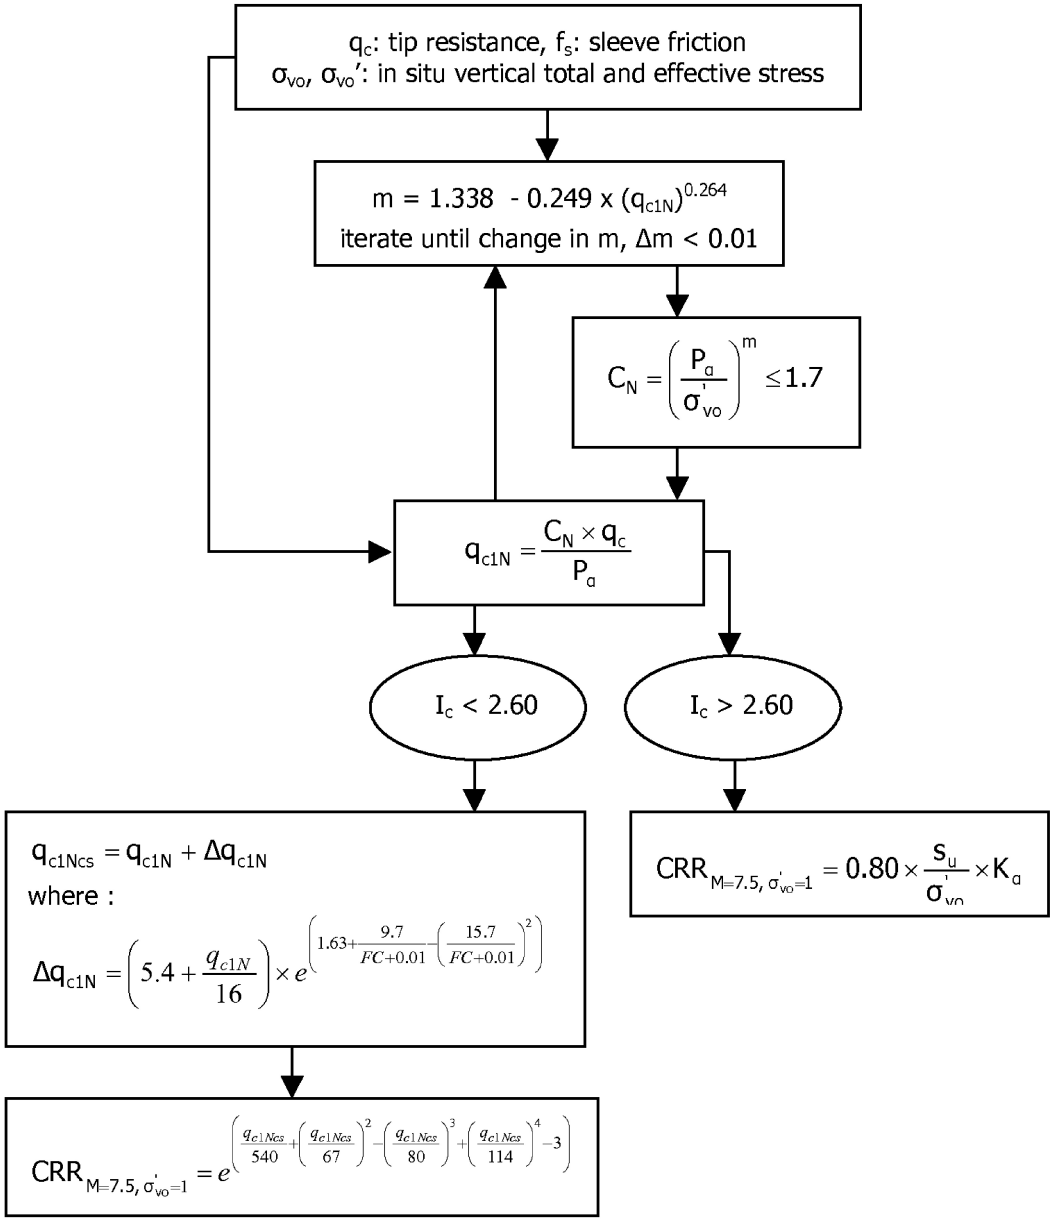
Procedure for the evaluation of soil liquefaction resistance (all soils), Robertson (2010)

Calculation of soil resistance against liquefaction is performed according to the Robertson & Wride (1998) procedure. This procedure used in the software, slightly differs from the one originally published in NCEER-97-0022 (Proceedings of the NCEER Workshop on Evaluation of Liquefaction Resistance of Soils). The revised procedure is presented below in the form of a flowchart[1]:

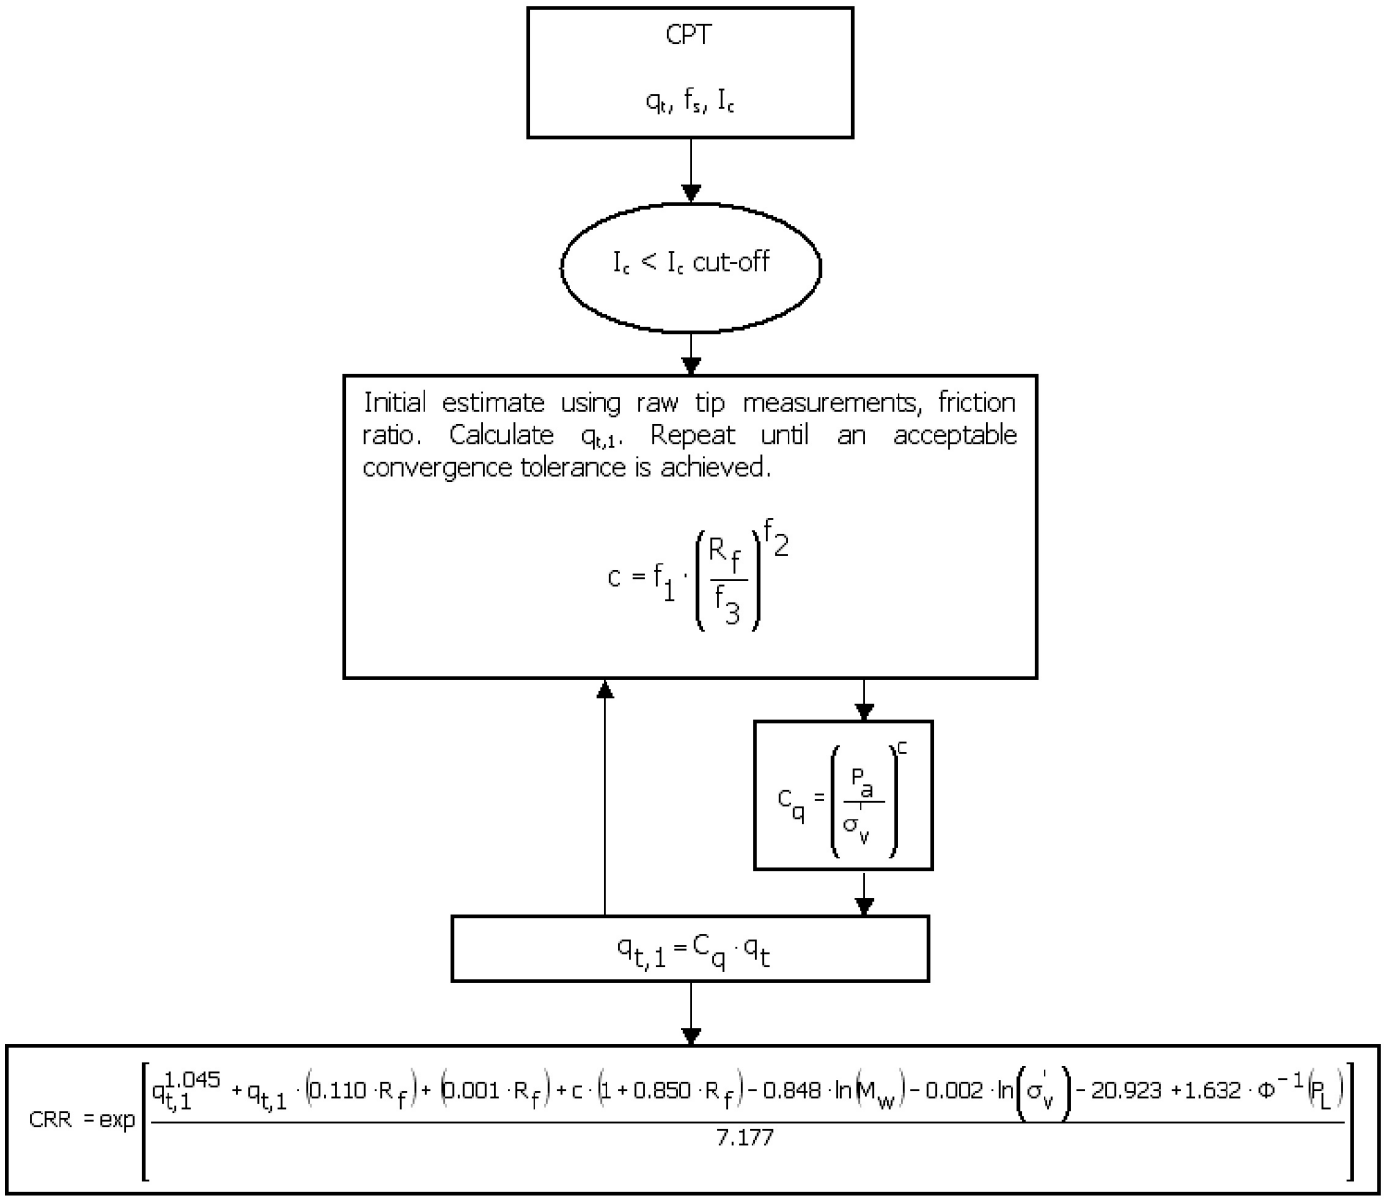


[1] P.K. Robertson, 2009. "Performance based earthquake design using the CPT", Keynote Lecture, International Conference on Performance-based Design in Earthquake Geotechnical Engineering – from case history to practice, IS-Tokyo, June 2009

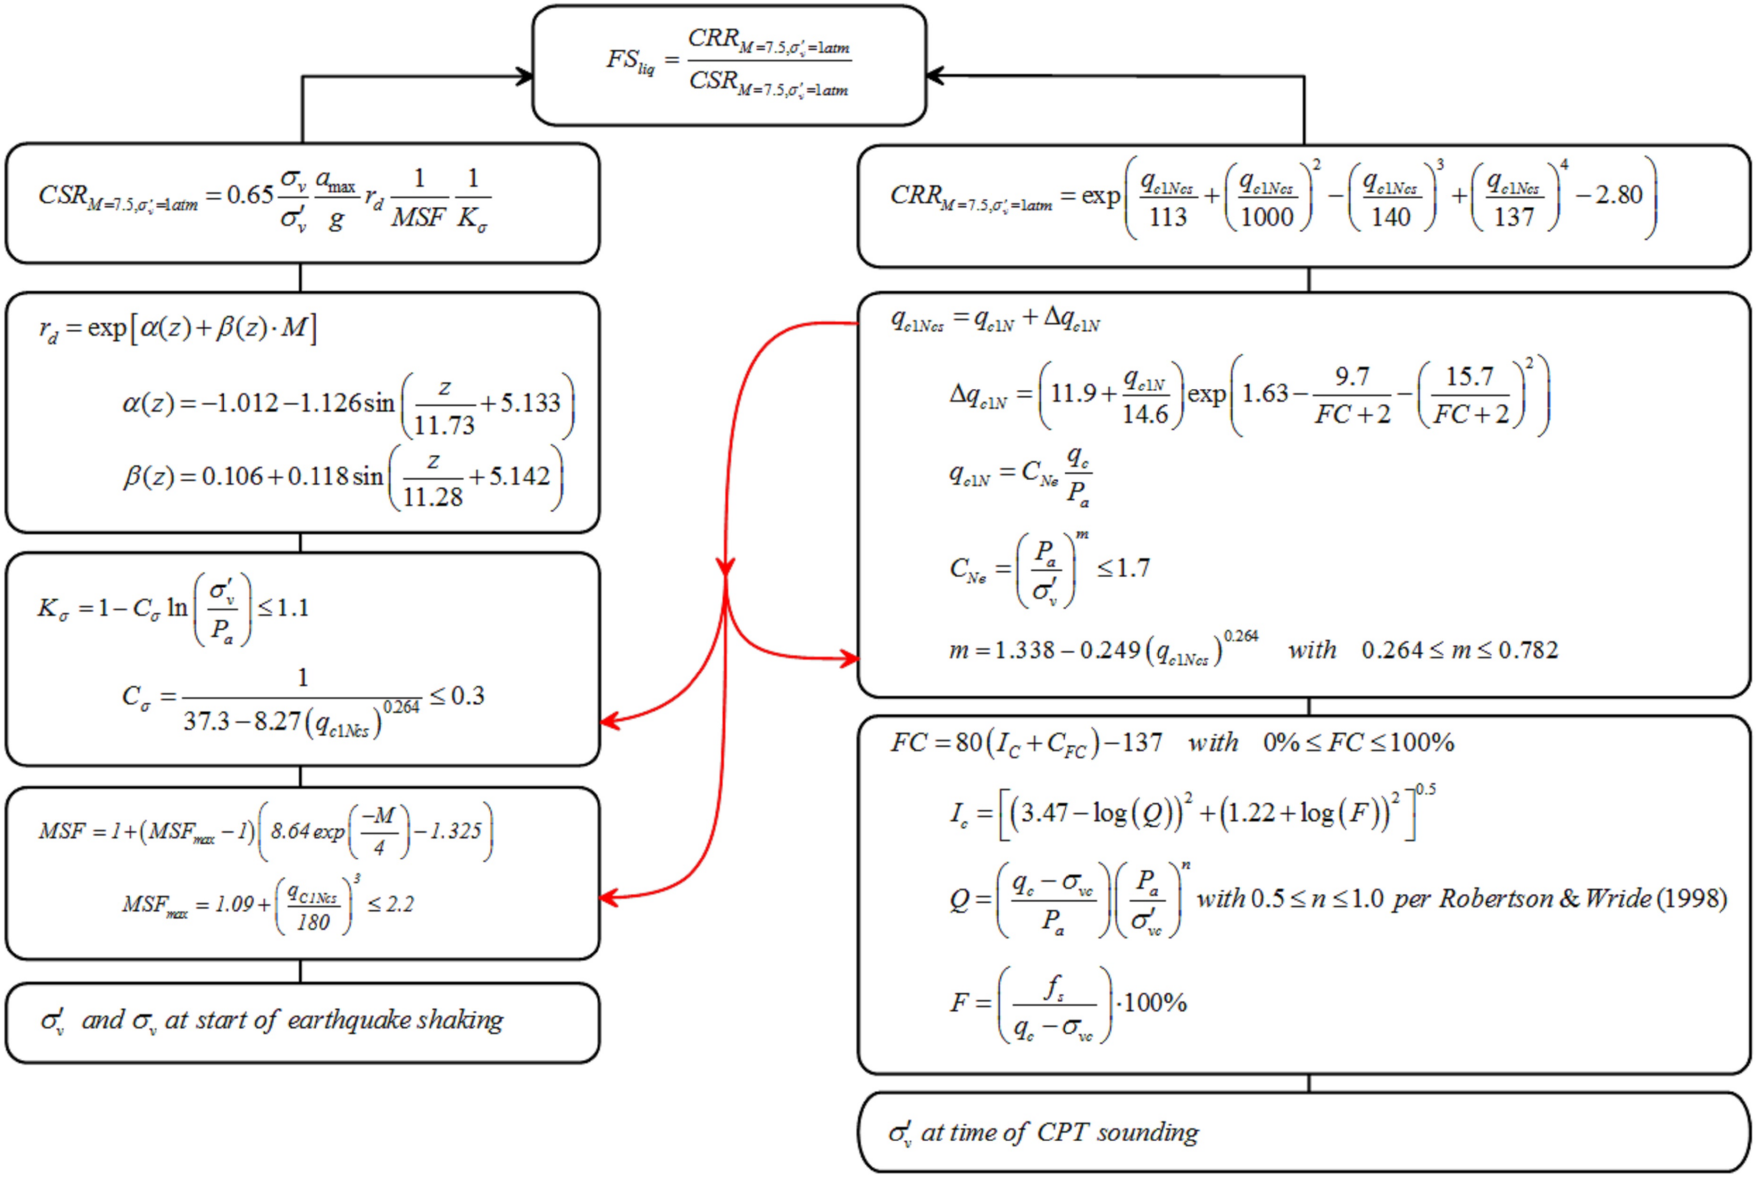
Procedure for the evaluation of soil liquefaction resistance, Idriss & Boulanger (2008)



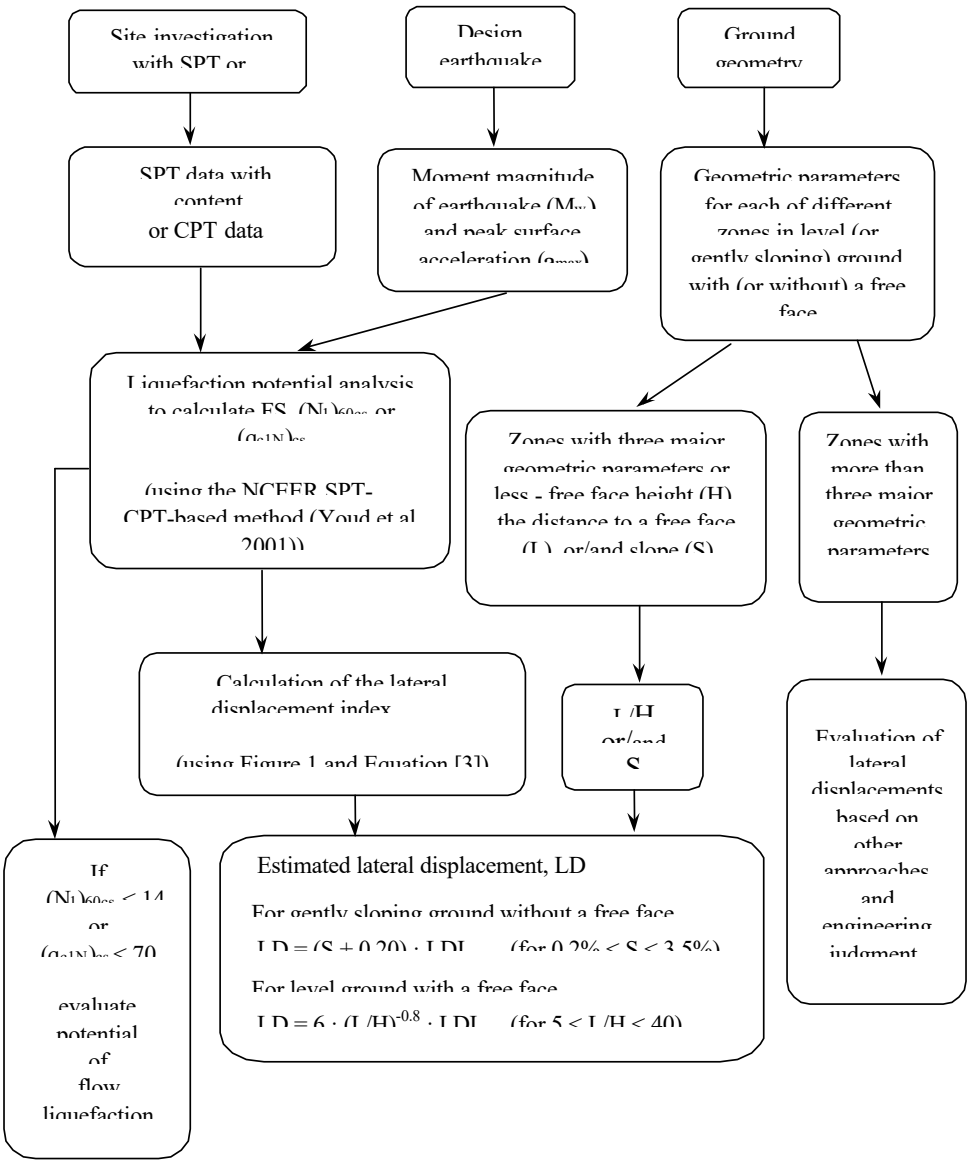
Procedure for the evaluation of soil liquefaction resistance (sandy soils), Moss et al. (2006)



Procedure for the evaluation of soil liquefaction resistance, Boulanger & Idriss(2014)



Procedure for the evaluation of liquefaction-induced lateral spreading displacements



[1] Flow chart illustrating major steps in estimating liquefaction-induced lateral spreading displacements using the proposed approach

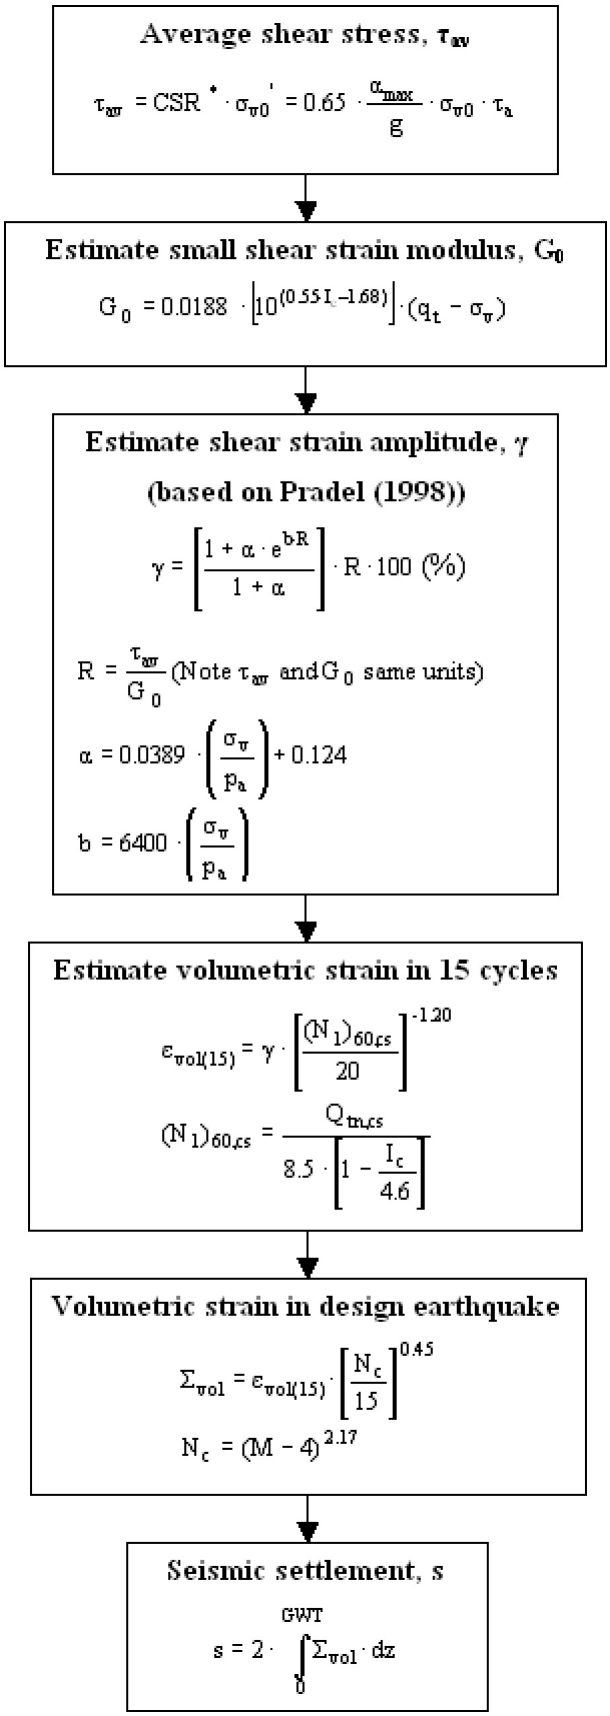
Procedure for the estimation of seismic induced settlements in dry sands



Robertson, P.K. and Lisheng, S., 2010, "Estimation of seismic compression in dry soils using the CPT" FIFTH INTERNATIONAL CONFERENCE ON RECENT ADVANCES IN GEOTECHNICAL EARTHQUAKE ENGINEERING AND SOIL DYNAMICS, Symposium in honor of professor I. M. Idriss, San Diego, CA

Liquefaction Potential Index (LPI) calculation procedure

Calculation of the Liquefaction Potential Index (LPI) is used to interpret the liquefaction assessment calculations in terms of severity over depth. The calculation procedure is based on the methology developed by Iwasaki (1982) and is adopted by AFPS.

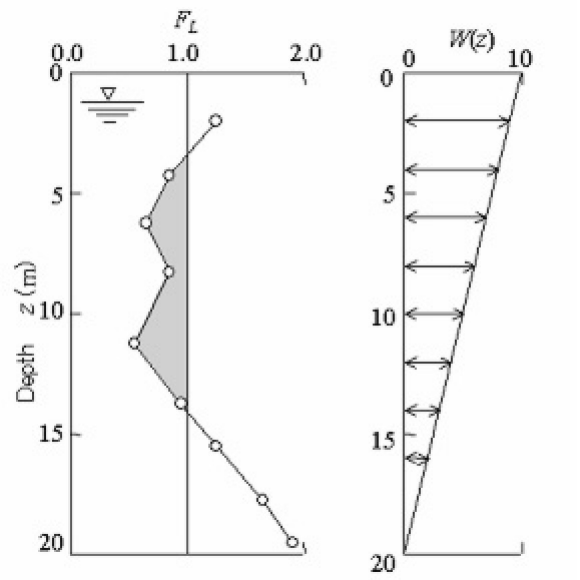
To estimate the severity of liquefaction extent at a given site, LPI is calculated based on the following equation:

$$\mathbf{LPI} = \int_0^{20} (10 - 0{,}5z) \times F_L \times dz$$

where:
F_L = 1 - F.S. when F.S. less than 1
F_L = 0 when F.S. greater than 1
z depth of measurment in meters

Values of LPI range between zero (0) when no test point is characterized as liquefiable and 100 when all points are characterized as susceptible to liquefaction. Iwasaki proposed four (4) discrete categories based on the numeric value of LPI:

- LPI = 0 : Liquefaction risk is very low
- 0 < LPI <= 5 : Liquefaction risk is low
- 5 < LPI <= 15 : Liquefaction risk is high
- LPI > 15 : Liquefaction risk is very high



Graphical presentation of the LPI calculation procedure

Shear-Induced Building Settlement (Ds) calculation procedure

The shear-induced building settlement (Ds) due to liquefaction below the building can be estimated using the relationship developed by Bray and Macedo (2017):

$$Ln(Ds) = c1 + c2 * LBS + 0.58 * Ln\left(Tanh\left(\frac{HL}{6}\right)\right) + 4.59 * Ln(Q) - 0.42 * Ln(Q)^2 - 0.02 * B + 0.84 * Ln(CAVdp) + 0.41 * Ln(Sa1) + \varepsilon$$

where Ds is in the units of mm, c1= -8.35 and c2= 0.072 for LBS ≤ 16, and c1= -7.48 and c2= 0.014 otherwise. Q is the building contact pressure in units of kPa, HL is the cumulative thickness of the liquefiable layers in the units of m, B is the building width in the units of m, CAVdp is a standardized version of the cumulative absolute velocity in the units of g-s, Sa1 is 5%-damped pseudo-acceleration response spectral value at a period of 1 s in the units of g, and ε is a normal random variable with zero mean and 0.50 standard deviation in Ln units. The liquefaction-induced building settlement index (LBS) is:

$$LBS = \sum W * \frac{\varepsilon_{shear}}{z} dz$$

where z (m) is the depth measured from the ground surface > 0, W is a foundation-weighting factor wherein W = 0.0 for z less than Df, which is the embedment depth of the foundation, and W = 1.0 otherwise. The shear strain parameter (ε_shear) is the liquefaction-induced free-field shear strain (in %) estimated using Zhang et al. (2004). It is calculated based on the estimated Dr of the liquefied soil layer and the calculated safety factor against liquefaction triggering (FSL).

SPT BASED LIQUEFACTION ANALYSIS REPORT

Project title : Swan Island Basin Remedial Design **Location : Portland, Oregon**

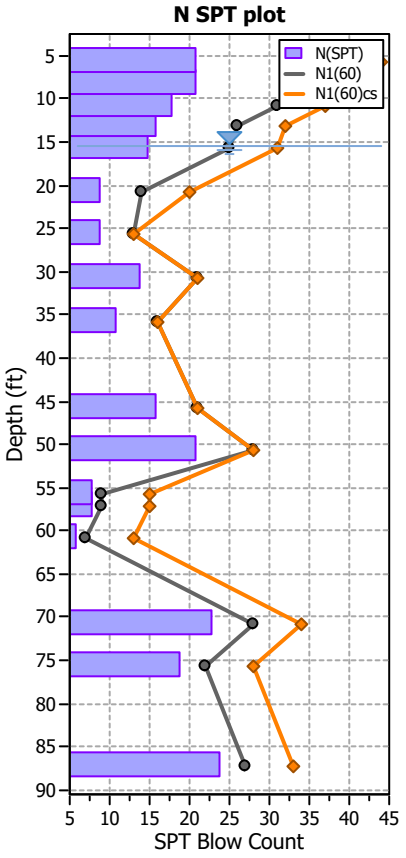
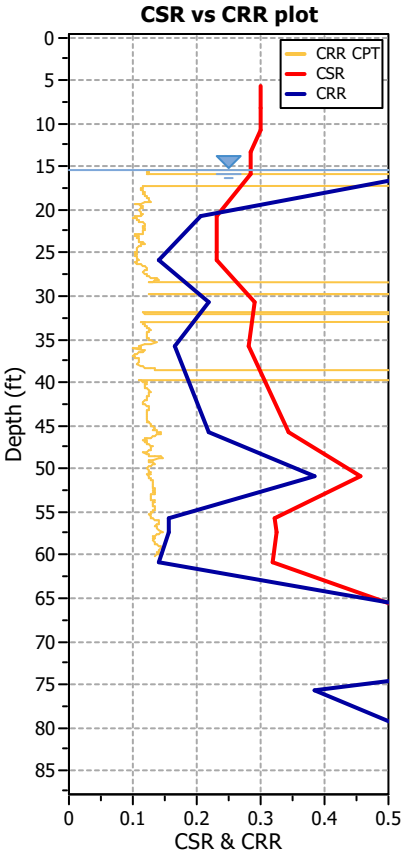
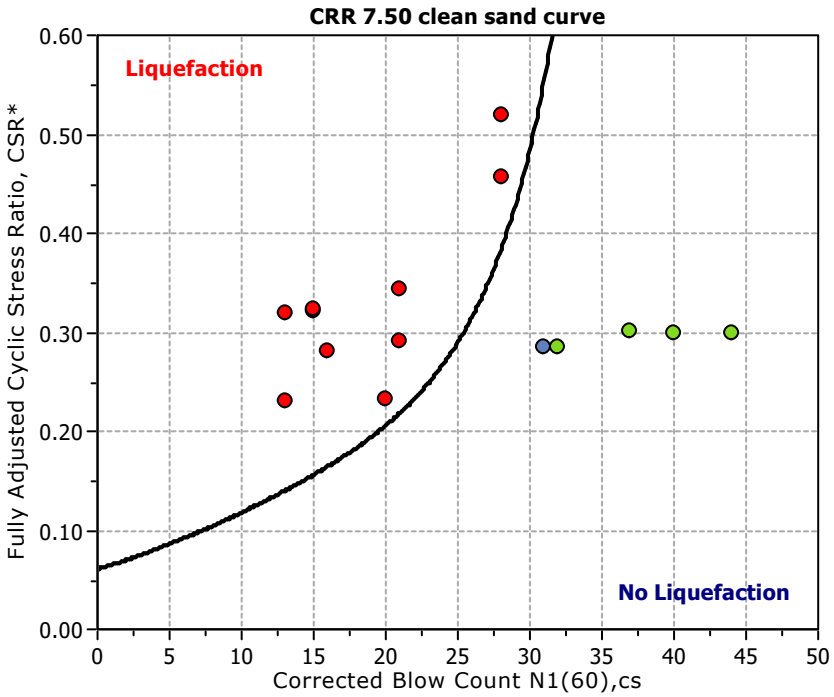
Borehole Name : B-13 (sCPTW-08)

:: Input parameters and analysis properties ::

Analysis method:	Idriss & Boulanger 2014	G.W.T. (in-situ):	15.37	EQ site conditions:	Same as initial
Fines correction method:	Idriss & Boulanger 2014	G.W.T. (earthq.):	15.37		
Sampling method:	Sampler wo liners	Earthquake magnitude M_w:	9.10		
Borehole diameter:	65 mm to 11 5mm	Peak ground acceleration:	0.24		
Rod length:	6.00	SPT results rounding mode:	Nearest		
Hammer energy ratio:	1.35				







:: Cyclic Stress Ratio fully adjusted (CSR*) numeric results ::

SPT BASED LIQUEFACTION ANALYSIS REPORT

Project title : Swan Island Basin Remedial Design **Location : Portland, Oregon**

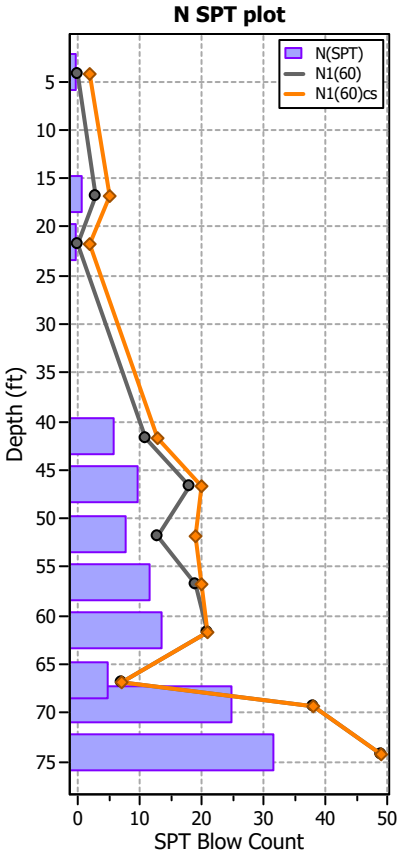
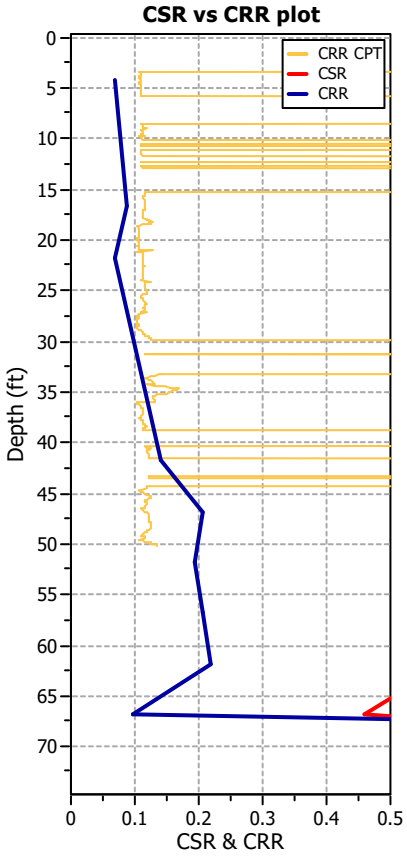
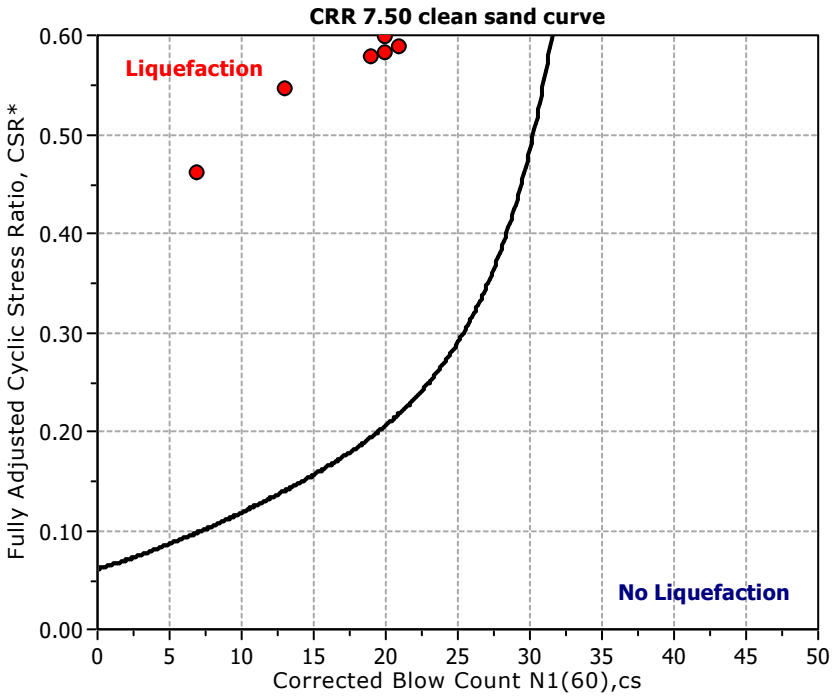
Borehole Name : BW-05 (sCPTW-05)

:: Input parameters and analysis properties ::

Analysis method:	Idriss & Boulanger 2014	G.W.T. (in-situ):	-21.00	EQ site conditions:	Same as initial
Fines correction method:	Idriss & Boulanger 2014	G.W.T. (earthq.):	-21.00		
Sampling method:	Sampler wo liners	Earthquake magnitude M_w:	9.10		
Borehole diameter:	65 mm to 11 5mm	Peak ground acceleration:	0.24		
Rod length:	17.00	SPT results rounding mode:	Nearest		
Hammer energy ratio:	1.47				







:: Cyclic Stress Ratio fully adjusted (CSR*) numeric results ::

SPT BASED LIQUEFACTION ANALYSIS REPORT

Project title : Swan Island Basin Remedial Design **Location : Portland, Oregon**

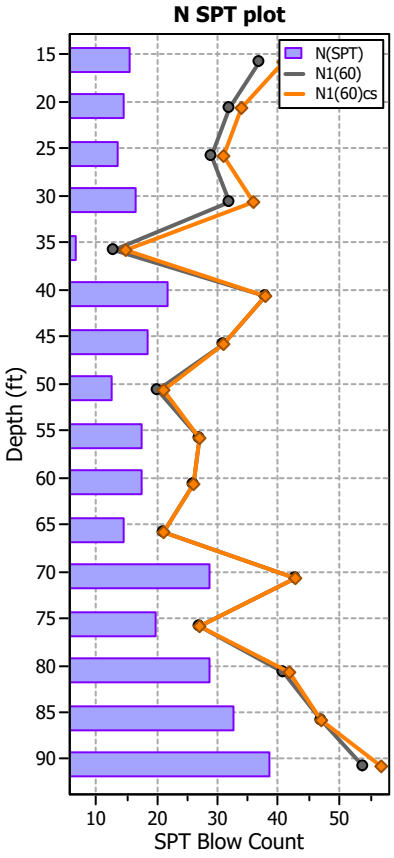
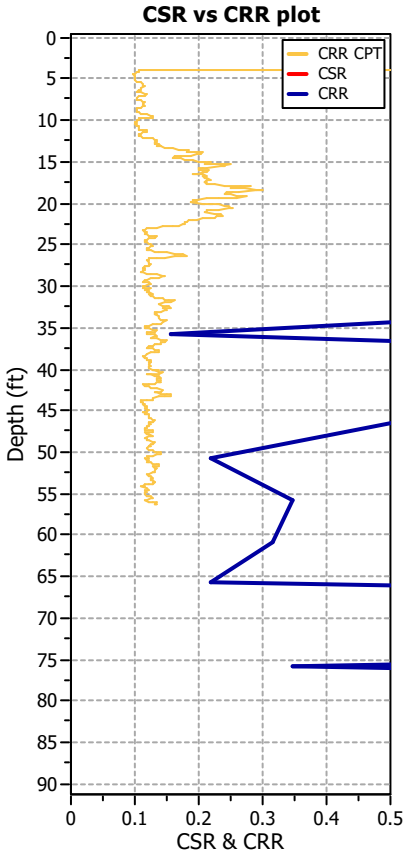
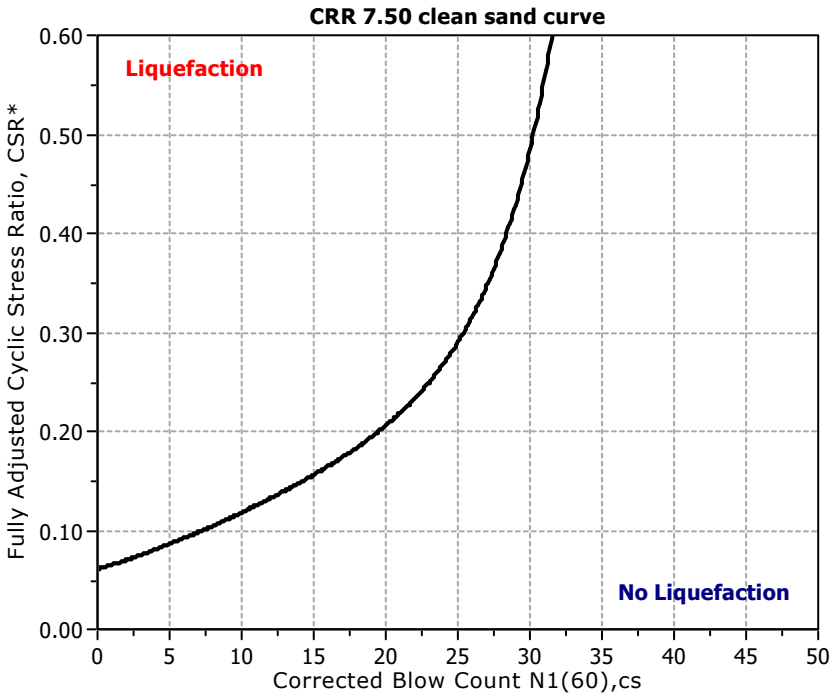
Borehole Name : BW-09 (sCPTW-11)

:: Input parameters and analysis properties ::

Analysis method:	Idriss & Boulanger 2014	G.W.T. (in-situ):	-61.08	EQ site conditions:	Same as initial
Fines correction method:	Idriss & Boulanger 2014	G.W.T. (earthq.):	-61.08		
Sampling method:	Sampler wo liners	Earthquake magnitude M_w:	9.10		
Borehole diameter:	65 mm to 11 5mm	Peak ground acceleration:	0.24		
Rod length:	57.08	SPT results rounding mode:	Nearest		
Hammer energy ratio:	1.47				







:: Cyclic Stress Ratio fully adjusted (CSR*) numeric results ::

ATTACHMENT C
CAP AND RIVERBANK STABILITY

1.0 INTRODUCTION

The following attachment to the Geotechnical Design Technical Memorandum presents the geotechnical evaluation specifically relating to the stability of the proposed cap and riverbanks of the Swan Island Basin (SIB) Project Area within the Portland Harbor Superfund Site in Portland, Multnomah County, Oregon.

2.0 DESIGN METHODOLOGY

2.1 GENERAL

Stability checks have been undertaken following the recommendations of the following documents:

- Remedial Design Guidelines and Considerations (EPA, 2021);
- Guidance for In-Situ Subaqueous Capping of Contaminated Sediments (Palermo et al., 1998);
- American Society of Civil Engineers (ASCE), Seismic Design of Piers and Wharves, ASCE 61-14 (ASCE, 2014); and
- Oregon Department of Transportation (ODOT) Geotechnical Design Manual (ODOT, 2024).

The bearing capacity of near-surface sediment was evaluated using methods from Palermo et al. (1998). The analysis, based on Terzaghi and Peck's (1967) bearing failure equations, estimates the maximum allowable cap thickness considering the cap's unit weight, the sediment's undrained shear strength, and a safety factor of 3.0.

Consolidation settlement of the sediment underlying the proposed cap was evaluated using Settle3 by Rocscience, a commercially available software that models time-dependent, one-dimensional consolidation behavior. This analysis is based on classical Terzaghi consolidation theory, which accounts for the gradual dissipation of excess pore water pressure and the resulting volume change in fine-grained soils under load. The evaluation considered the unit weight of the cap materials, the compressibility characteristics of the underlying sediments, and the anticipated loading conditions. The methodology aligns with the guidance provided in EPA's Remedial Design Guidelines and Considerations (2021), Palermo et al. (1998) for in-situ capping of contaminated sediments, and the ODOT Geotechnical Design Manual (2024), ensuring that the predicted settlements are within acceptable limits for long-term cap performance and stability.

Dredge prism and riverbank stability was assessed using two-dimensional limit equilibrium methods implemented in Slide2 by Rocscience. The Spencer method was applied to evaluate circular failure surfaces, with critical slip surfaces analyzed to depths exceeding 5 feet (ft). The slope geometry and soil parameters used in the analysis were derived from site-specific investigations and aligned with the methodologies outlined in EPA's Remedial Design Guidelines and Considerations (2021) and Palermo et al. (1998).

The factor of safety (FoS), defined as the ratio of resisting to driving forces or moments, was used as the primary metric for evaluating slope stability. As FoS approaches 1.0, the potential for deformation increases significantly, with instability occurring at or below unity. Given the time-dependent behavior of fine-grained soils, particularly their sensitivity to loading rate and drainage conditions, analyses were conducted for both short-term (undrained) and long-term (drained) loading scenarios.

For static analysis, a minimum FoS of 1.3 for short-term construction conditions and 1.5 for long-term static conditions is recommended (ODOT, 2024). For pseudo-static (non-liquefied) analysis, a minimum safety factor of 1.1 is recommended (ODOT, 2024). The actual FoS may vary due to uncertainties in soil strength, subsurface geometry, failure surface locations and orientations, and groundwater levels.

2.2 DESIGN INFORMATION

2.2.1 Geometry

The existing riverbank (from top of slope to basin) varies in both height and slope angle. Table 2-1 summarizes the geometry assumed in stability analysis for each of the SIB Project Area-sub areas. The critical cross sections have been selected based on the height and inclination of the slope along the section.

Table 2-1
Riverbank Slope Geometry

SIB Design Areas	Approximate Height of Slope (max)[a]	Existing Gradient of Slope (max)[b]	90% RD Slope Gradient (max)
U.S. Coast Guard	48’	2.2H:1V	2.75H:1V
U.S. Navy	53’	2.4H:1V	2.5H:1V
The Marine Consortium, Inc.	50’	2.1H:1V	2.1H:1V (with pinning piles) 2.5H:1V (no reinforcement)
Port or Portland Dredge Base	45’	2.5H:1V	2.5H:1V
ATC Leasing Co.	49’	1.7H:1V	3H:1V
Berth 311	53’	3H:1V	3H:1V
Berths 306, 307 & 308	49’	1.7H:1V	2.5H:1V (new structures)
SCC Floating Docks	83’	1.7H:1V	2.75H:1V
East, West and Demo Pier	85’	1.6H:1V	2.75H:1V

Notes:
[a] Height of slope taken from approximate top of slope to basin depth
[b] Existing slopes are typically undulating, max gradient taken at steepest portion of slope.
max = maximum
RD = Remedial Design

2.2.2 Ground Model and Geotechnical Parameters

Subsurface ground models are presented in Section 2.4 of the main body of the text. Geotechnical design parameters used in bearing capacity and riverbank stability checks are presented in Table 2-2.

Table 2-2
Geotechnical Parameters for Bearing Capacity and Slope Stability

Engineering Soil Unit	Unit Weight γ (pcf)	Angle of Internal Friction φ' (degrees)	Cohesion c' (psf)	Undrained Shear Strength Su (psf)
Existing material				
Artificial Fill	110	35	0	-
Recent Basin Sediment – Mocks Bottom	105	33	0	-
Recent Basin Sediment – Swan Island	95	33	0	200 - 300
Alluvium – Coarse	115 @ EL ≥ 0 ft 120 @ EL < 0 ft	32 – 34 @ EL ≥ -10 ft 34 – 36 @ EL < -10 ft	0	-
Alluvium – Fine	105	26	150	800 @ EL ≥ -5 -20(EL+5) + 800 @ EL < -5 (max 1,450 psf)
Missoula Flood Deposits – Fine – Mocks Bottom	110	33	150	1,100 @ EL ≥ -8 -10(EL+8) + 1,100 @ EL < -8 (max 1,500 psf)
Missoula Flood Deposits – Fine – Swan Island	110	33	150	1,500 @ EL ≥ -8 -25(EL+8) + 1,500 @ EL < -8 (max 2,500 psf)
Missoula Flood Deposits - Coarse	120	34 @ EL ≥ -80 ft 36 @ EL < -80 ft	0	-
Proposed material				
Revetment - Rock Armor	150[a]	42	0	-
Granular fill	125	36	0	-

Notes:
[a] Unit Weight of Riprap protection as presented in U.S. Army Corps of Engineers Engineering Manual EM 1110-2-1601 Chapter 3 Hydraulic Design of Flood Control Channels.
EL = elevation
pcf = pounds per cubic foot
psf = pounds per square foot

2.2.3 Design Water Levels and Piezometric Line

Groundwater has been observed during the field investigations across the SIB Project Area. The groundwater elevations are generally in accordance with water level in the basin. For the riverbank stability checks, analysis has been undertaken using both Ordinary High Water (+20.1 ft North American Vertical Datum of 1988 [NAVD88]) and +5.1 ft NAVD88 for the full extent of the riverbank. The low water level (+5.1 ft NAVD88) represents an estimate of low water values reached during low tides during the summer, based on measured Willamette River water levels. It

is noted that in the majority of scenarios, a higher surface water level within the basin will provide a stabilizing force to the toe of the slope. Sensitivity analysis was undertaken using to determine the critical analyses and impact of varying design water levels.

2.2.4 Loading Conditions

2.2.4.1 Imposed Loading

Excavation activities will be required along the crest of the riverbank during construction. Typical live load surcharges from construction or traffic may be estimated using a surface pressure of 250 psf as per the ODOT Geotechnical Design Manual (ODOT, 2024).

2.2.4.2 Earthquake Loading

A horizontal seismic coefficient of 0.12 was used in pseudo-static stability analyses. The horizontal seismic coefficient was estimated as a half of the mapped peak ground acceleration of 0.234 g (2018 Conterminous U.S. National Seismic Hazard Map) for a 10 percent probability in 50 years (475-year) return period.

3.0 CAP GEOTECHNICAL DESIGN

3.1 GENERAL

In the majority of locations the proposed cap will be placed on the soft existing sediment and therefore consolidation of the underlying material is expected. The following section details the results of geotechnical analysis for proposed cap design across the site.

3.2 BEARING CAPACITY

Within the SIB Project Area, the existing mud line is primarily composed of soft fine grained basin sediments. The analysis undertaken evaluated the steady-state short-term stability of the cap and soft sediments during construction. The in situ material must have sufficient strength to prevent local shear failure. Ultimate bearing capacity was therefore calculated based on bearing failure equations (Terzaghi and Peck, 1967). A lower bound global undrained shear strength of 200 psf was applied for this analysis.

The ultimate bearing capacity was calculated as follows:

$$q_{ult} = \frac{2}{3} \times 200\ psf\ x\ 5.14 = 685\ psf$$

A factor of safety of 3 was used to calculate the allowable bearing capacity:

$$q_{all} = \frac{q_{ult}}{FoS} = \frac{685}{3} = 228\ psf$$

The initial cap lift thickness (H_{all}) that could be supported by the lower bound in situ sediments at an appropriated FoS was calculated using the allowable bearing capacity and the assumed buoyant weight of the cap material (assumed average of erosion protection layer and sand cap = 65 pcf).

$$H_{all} = \frac{q_{all}}{\gamma'} = \frac{228}{65} = 3.5\ ft$$

The estimated allowable cap lift thickness is 3.5 ft. This is based on dredge areas and where the cap is being placed on top of soft recent basin sediments. It is understood the maximum cap thickness will be 3 ft. The above 0.5 ft allowable overfill should be considered by the construction team. If more fill is required consideration should be made to staged placement.

To ensure the recommended cap lift thickness performs effectively and mitigates the risk of localized bearing failures during construction, an observational approach should be adopted. This approach would involve regular evaluations of contractor activities and progress surveys. Should these evaluations indicate signs of localized bearing capacity issues, adjustments to the construction methods may be required. These adjustments could include slowing the rate of material placement or applying the material in thinner layers to minimize stress on the underlying sediments.

3.3 CONSOLIDATION SETTLEMENT

As the proposed cap is a not a fine grained material (defined as material with less than 50% by weigh passing a #200 sieve), no consolidation of the cap is assumed (EPA, 1998). However, the load from the cap will result in consolidation of the underlying sediments. Consolidation analysis is therefore required to address two items noted in the Guidance for In-situ subaqueous capping of contaminate sediments (EPA,1998):

1) To inform and accurately interpret monitoring data, distinguishing between changes in cap elevation due to consolidation versus erosion.

2) To evaluate the potential for advective contaminant flux resulting from consolidation-induced pore pressure changes.

The compressible layers that exist at the site are the silt and clay layers associated with the recent basin sediments, alluvium and Missoula Flood Deposits. Consolidation properties for the underlying materials have been estimated through laboratory testing and empirical correlations presented in Attachment A.

To assess the consolidation of the cap, ground models were developed based on the in-water field investigation. Consolidation was then evaluated where the compressible materials are expected to be thickest. Following a review of the proposed dredging plan and ground models, it was determined that the post-dredge thickness of compressible basin sediment layers were thicker at the head of the basin. The following worst credible ground model used for settlement analysis is based on field investigation position BW-05 at the head of SIB where no dredging is proposed and recent sediment deposits are at the thickest. Results of the consolidation analysis are presented below.

Table 3-1
Consolidation Analysis Results

Layer	Material	Layer Depth (ft)	Cc	OCR	e_0	K (ft/year)	Consolidation Settlement per layer (inch)
1	Recent Basin Sediment - Silt	0 – 10	0.9	1.5	2	0.103	12
2	Recent Basin Sediment - Silt	10 – 13.25	0.9	1	1.7	1.03	6
3	Recent Basin Sediment - Sand	13.25 - 28	-	-	-	-	-
4	Missoula Flood Deposits - Silt	28 -37.5	0.9	1	1.7	10.03	1
5	Missoula Flood Deposits - Sand	37.5 – 46.5	-	-	-	-	-
6	Missoula Flood Deposits - Silt	47.5 - 54	0.4	1	1.1	10.3	>1

Settlement analysis indicates that, under a load equivalent to a 3.5-foot cap lift, approximately 20 inches of total consolidation settlement (including both primary and secondary settlement) is expected.

The consolidation settlement estimates presented above are based on the worst credible ground model and assume no dredging, representing a net load increase. It is acknowledged that the underlying materials across the project site will respond differently to imposed loading due to spatial variability in sediment type and geometry. To assess this, a sensitivity analysis was conducted considering variations in site geometry (dredge and cap vs. no dredge and cap) and sediment characteristics (predominantly cohesionless vs. predominantly cohesive). The resulting maximum differential settlement across these scenarios is estimated to range between 15 and 25 inches. Importantly, this variation is expected to manifest as a gradual slope in the top surface of the environmental cap, rather than abrupt deformation. Given that the cap is composed of granular materials, which do not undergo consolidation, its structural integrity and performance are not expected to be compromised by the underlying differential settlement.

It is important to note that subgrade consolidation can affect interpretation of bathymetric survey data used to confirm cap thickness. Settlement may be misread as cap “thinning” when surveys are interpreted. Integrating thickness probing with routine bathymetric surveys will help ensure that maintenance decisions are based on accurate interpretations of settlement and cap integrity, supporting long-term stability and effectiveness of the environmental cap.

4.0 RIVERBANK GEOTECHNICAL DESIGN

4.1 GENERAL

The following section details the results of stability analysis for unreinforced riverbank sections across the project site. Global stability analysis for new structures, specifically replacements for Berth 306 and 307, Marine Consortium Pinning Piles and United States Coast Guard Toe Wall are

discussed in Attachment D. Stability analysis for Pier A and Quay Wall are presented in Attachment E.

4.2 STATIC SLOPE STABILITY

The static stability of the riverbank has been assessed based on the current and proposed geometry of critical project-sub areas and sub-surface conditions. The results (FoS) of the stability analyses are presented below and in Figures C-1 to C-7.

Table 4-1
Static Slope Stability

Project-sub area	Geological Section	Existing Condition	Design Slope Angle	Proposed Design - Construction	Proposed Design - Long Term
USCG	A-A'	1.3	2.75H : 1V	1.5	1.7
Navy	B-B'	1.2	2.5H : 1V	1.5	1.6
MC	D-D'	1.2	2.5H : 1V	1.4	1.5
Dredge Base	E-E'	1.4	2.5H : 1V	1.5	1.6
ATC Leasing	F-F'	2.4	3H : 1V	1.5	1.7
Berth 311	G-G'	1.0	3H : 1V	1.6	1.7
Berths 306, 307 & 308	J-J'	1.4	2.5H : 1V	1.7	1.6
Vigor Shipyard	Q-Q'	1.4	2.5H : 1V	1.6	1.7

Notes:
% = percent
SCC = Shipyard Commerce Center
USCG = U.S. Coast Guard

As seen above, the majority of the slopes are marginally stable in the current static condition. This slope instability may manifest as a rotational landslide, extending from the crest of the slope to the low water level within the basin. The remedial design slopes have therefore been configured to target a FoS of 1.5 for slopes.

4.3 PSEUDO-STATIC SLOPE STABILITY

The pseudo-static stability of the riverbank has been assessed based on the current and proposed geometry of each project-sub area and sub-surface conditions. The results (FoS) of the stability analyses are presented below and in Figures C-1 to C-7. The seismic displacement calculation was performed per procedure suggested by Macedo et al. (2023) for the Navy and MC pier slopes (B-B' and D-D') with FoS less than 1.1. The corresponding estimated seismic slope displacements are 0.37 ft and 0.47 ft for subsurface sections B-B' and D-D', respectively.

Table 4-2
Pseudo-Static Slope Stability

Project-sub area	Geological Section	Existing Condition	Proposed Design - Long Term
USCG	A-A'	1.0	1.1
Navy	B-B'	0.9	1.0
MC	D-D'	1.0	1.0
Dredge Base	E-E'	1.0	1.1
ATC Leasing	F-F'	1.3	1.1

Project-sub area	Geological Section	Existing Condition	Proposed Design - Long Term
Berth 311	G-G'	0.9	1.1
Berths 306, 307 & 308	J-J'	0.8	1.1
Vigor Shipyard	Q-Q'	0.6	1.1

4.4 PERFORMANCE OF RIVERBANK SLOPES

Under current conditions, many riverbank slopes within the project area exhibit marginal static stability, with calculated static and pseudo-static FoS ranging from approximately 0.9 to 1.2 and 0.6 to 1.0 respectively. To improve long-term stability, the remedial design includes regrading and flattening the slopes to achieve a minimum static FoS of 1.5 and pseudo-static FoS of 1.1.

Each design area has been analyzed using existing slope geometry, subsurface conditions, and groundwater data. In general, the riverbanks will be regraded to a maximum slope of 2.5 horizontal to 1 vertical (2.5H:1V) without requiring additional reinforcement. Temporary excavations should also not exceed this slope gradient. To further enhance slope resilience and mitigate surface erosion or shallow sloughing, a riprap revetment layer is included in the remedial design.

While the proposed improvements in static and pseudo-static stability significantly enhance slope safety, seismic-induced ground failures, particularly liquefaction and lateral spreading in vulnerable soil layers, remain a concern. These phenomena could result in substantial ground deformation along the riverbank, even after remedial measures are applied. A sensitivity analysis has been conducted to explore whether additional steps, such as further flattening slopes or increasing cap thickness, could enhance seismic performance. However, these measures were deemed to not improve the post-earthquake condition to a satisfactory level. Consequently, while the slope geometry and stability will see notable improvements, additional strategies may be necessary to mitigate liquefaction-related risks during seismic events. Deep soil mixing and stone columns could mitigate these hazards but are not considered applicable on a cost-benefit consideration. Instead, a focus on post-seismic maintenance and repair measures is recommended to manage damage following liquefaction-triggering seismic events.

ATTACHMENT D
NEW MARINE STRUCTURES

1.0 INTRODUCTION

The following attachment to the Geotechnical Design Technical Memorandum (GDTM) presents the geotechnical stability evaluation specifically relating to the new marine structures required as part of the Remedial Design (RD).

It is important to note that the design of new structures is at a 30% design maturity, and as such, all recommendations provided within this document reflect that level of development.

2.0 U.S. COAST GUARD RETAINING WALL

2.1 GENERAL

A cantilever sheet pile wall will be constructed as part of the RD at the U.S. Coast Guard (USCG). The sheet pile will be constructed between the USCG pier and the floating dock structures. The sheet pile wall is required to enable dredging to specified navigation depths around the USCG pier and floating dock while maintaining stability of the sloping ground above.

2.2 DESIGN INFORMATIOON

2.2.1 Geometry

The geometry of the proposed sheet pile wall is presented below. Further details on the location and geometry of the sheet pile wall section is described in Structural Design Technical Memorandum (Volume I, Appendix J). The below geometry represents the critical section used for the geotechnical analysis.

Table 2-1
USCG Toe Wall Geometry

Design Element	Value
Sheet pile section	NZ38
Total Length	50 ft
Retained Height – construction during dredging	17 ft
Retained Height – final condition with cap	12 ft
Min embedment depth – construction during dredging	33 ft
Min embedment depth – final condition with cap	38 ft
Slope angle above wall	2.75H : 1V
Top of wall elevation	5.6 ft NAVD88

Notes:
ft = feet/foot
Min = minimum
NAVD88 = North American Vertical Datum of 1988

2.2.2 Ground Model and Geotechnical Parameters

The stratigraphy is based on Subsurface Profile A-A (Figure 2-1b, of the GDTM). The design ground model is summarized below, geotechnical parameters have been applied based on Table 3-1 in the GDTM. The water level considered in the model is at the elevation +5.1 ft NAVD88, which represents an estimate of low water values reached during low tides during the summer, based on measured Willamette River water levels.

Table 2-2
USCG Toe Wall – Design Ground Model

Stratigraphy	Layer Top Depth (ft)	Layer Bottom Depth (ft)	Total Unit Weight (pcf)	Friction angle (°)	Cohesion (psf)	Undrained Shear Strength (psf)
Artificial Fill	0	3.1	110	34	-	-
Alluvium – Sand	3.1	27.5	115	33	-	-
Alluvium – Clay	27.5	45.2	105	24	75	1,300[a]
Missoula Flood Deposits - Silts	45.2	-	110	32	150	1,500

Notes:
a) Averaged undrained shear strength over layer.
° = degrees
pcf = pounds per cubic foot
psf = pounds per square foot

2.2.3 Seismic Parameters

The sheet pile wall is being constructed to satisfy the Remedial Action (RA), specifically enable the capping design requirements of the project. Therefore, in accordance with Remedial Design Guidelines and Considerations, Portland Harbor Superfund Site (EPA, 2021), the design of the sheet pile wall considers the seismic shaking demands of the Contingency Level Earthquake (CLE) only.

The CLE is defined as a seismic event associated with a 475-year return period. This corresponds to a peak ground acceleration (PGA) of 0.23g, according to the U.S. Geological Survey (USGS) hazard tool. In accordance with guidelines from Oregon Department of Transportation (ODOT, 2024) and American Association of State Highway and Transportation Officials (AASHTO, 2020), this was applied in a pseudo-static analysis using a horizontal acceleration factor kh = 50% PGA (0.12).

2.2.4 Loading Conditions

Typical live load surcharges have been estimated using a surface pressure of 250 psf as per the ODOT Geotechnical Design Manual (ODOT, 2024). This has been applied to the top of the slope during construction and operation.

2.3 EARTH PRESSURES

Static earth pressures acting on the sheet pile wall have been estimated using the Coulomb wedge method on the active side and Caquot and Kerisel (1948) method on the passive side. Both methods calculate the active and passive pressures based on the wall-soil friction angle ($\delta = 0.67\varphi'$), the internal friction angle of the soil (φ') and the sloping backfill.

Mononobe-Okabe (M-O) method (Mononobe and Matsuo 1929; Okabe 1924) has been used to estimate the seismic earth pressures acting on the sheet pile wall. The M-O method is one of the simplest methods to estimate seismic earth pressure. The method can be implemented in limit equilibrium modelling by applying a horizontal acceleration (k_h) to the model. The resulting active seismic earth pressure was distributed above the excavation level as shown in AASHTO Figure 11.8.6.2-1, Section 11.8.6. In the determination of seismic passive pressures, a reduction factor of 0.67 has been applied to limit displacement required to mobilize the passive earth pressure.

2.4 LIMIT STATES

The sheet pile wall has been designed in accordance with AASHTO (2020). The geotechnical design of the cantilever sheet pile wall has been undertaken following the limit states defined by Load and Resistance Factor Design (LRFD) design methodology stated below.

- Strength Limit State (AASHTO Article 11.8.4):
    - Global stability of the slope / soil mass.
    - Soil passive failure due to insufficient embedment of the sheet pile wall.
- Extreme Limit State (AASHTO Articles 11.8.6):
    - Global stability of the slope / soil mass.
    - Soil passive failure due to insufficient embedment of the sheet pile wall.

Global stability of the soil mass has been evaluated with 2D limit-equilibrium analysis (Spencer Method) using Slide2 (Version 9.03) by Rocscience. Global stability is assessed using the factor of safety (FoS), which is the ratio of resisting forces or moments to driving forces or moments. The Global stability relating to the embedment depth has been evaluated with 2D limit-equilibrium analysis using DeepEX (Version 24.03) by Deep Excavation LLC.

Structural design of the Sheet pile wall is addressed in Appendix J of the RD.

2.5 RESULTS

2.5.1 Stability

The FoS values obtained from stability analyses carried out in Slide2 and DeepEX are shown in **Table 2-3**.

Table 2-3
Factor of Safety (FoS) Values for Global and Embedment Depth of Sheet Pile Wall

Stage	Limit State	Design check	Recommended FoS	Design FoS
Construction	Strength Limit State	Global Slope Stability	1.3	1.4
		Wall Embedment depth		1.5
Final	Strength Limit State	Global Slope Stability	1.5	1.9
		Wall Embedment depth		2.0
Final	Extreme Limit State [a]	Global Slope Stability	1.1	1.2
		Wall Embedment depth		1.5

Notes:
a) Does not include liquefaction case – refer to Section 2.2.3

3.0 THE MARINE CONSORTIUM, INC. – SLOPE STABILIZATION

3.1 GENERAL

In order to stabilize the cap and associated slopes at the Marine Consortium riverbank, two rows of sheet pile wall are proposed in slopes steeper than 2.5H:1V. The sheet piles will act to resist lateral soil movements, intercepting potential failure surfaces and therefore enhancing the global stability of the retained soil mass.

The below section details the geotechnical design of the slope stabilization measures. The structural design approach is presented in Structural Design Technical Memorandum (Volume I, Appendix J).

3.2 DESIGN INFORMATION

3.2.1 Geometry

The geometry of the proposed slope stabilization walls is presented below. Further details on the location and geometry of the sheet pile wall section are described in Appendix J – Structural Design Technical Memo. The below geometry represents the critical section used for the geotechnical analysis.

Table 3-1
Marine Consortium Slope Stabilization Walls – Geometry

Design Element	Value
Sheet pile section	NZ 38
Total wall length (section)	80 - 100 ft
Total wall length (linear length)	500 ft (approximate)
Global Slope angle of slope	2.15H : 1V
Approximate elevation of top row	19 ft NAVD88
Approximate elevation of top row	3 ft NAVD88

3.2.2 Ground Model and Geotechnical Parameters

The ground strata and properties for the analyses were derived from the Geotechnical Data Report (Appendix F of the PDI ER; HGL, 2024). Stratigraphy is shown in subsurface Profiles C-C and D-D (Figure 2-1d and e, GDTM). Profile D-D was deemed more critical following sensitivity analysis, forming the basis of the design ground model summarized below. Geotechnical parameters follow Table 3-1 in the GDTM. The water level considered is elevation +5.1 ft NAVD88, which represents an estimate of low water values reached during low tides during the summer, based on measured Willamette River water levels.

Table 3-2
Marine Consortium – Design Ground Model – Upper Pile Row

Stratigraphy	Layer Top Depth (ft)	Layer Bottom Depth (ft)	Total Unit Weight (pcf)	Friction angle (°)	Cohesion (psf)	Undrained Shear Strength (psf)
Revetment	19	16	150	42	-	-
Alluvium – Sand	16	5	115	33	-	-
Alluvium – Clay	5	-5	105	24	75	800
Alluvium – Clay	-5	-39	105	24	75	-20(EL+5) + 800 (max 1,450)

Missoula Flood Deposits - Silts	-65	-100	110	32	150	-10(EL+8) + 1,100 (max 1,500)

3.2.3 Seismic Parameters

The sheet pile wall is being constructed to satisfy the RA, specifically to enable the capping design requirements of the project. Therefore, in accordance with Remedial Design Guidelines and

Considerations (EPA, 2021), the design of the sheet pile wall considers the seismic shaking demands of the CLE only.

The CLE is defined as a seismic event associated with a 475-year return period. This corresponds to a PGA of 0.23g, according to the USGS hazard tool. In accordance with guidelines from ODOT (ODOT, 2024) and AASHTO (AASHTO, 2020), this was applied in a pseudo-static analysis using a horizontal acceleration factor kh = 50% PGA (0.12).

3.2.4 Loading Conditions

Typical live load surcharges have been estimated using a surface pressure of 250 psf as per the ODOT Geotechnical Design Manual (ODOT, 2024). This has been applied to the top of the slope during construction and operation.

3.3 LIMIT STATES

The geotechnical design of the slope stabilization wall has been undertaken following the limit states defined by LRFD design methodology, presented in ODOT, 2024 Section 7.

Table 3-4
Minimum Required FoS and Maximum Required Resistance Factors Reproduced from Section 7 and in ODOT, 2024

Geotechnical Item under consideration	Limit State	Minimum Factor of Safety	Maximum LRFD Resistance Factor	Load Factor
Slopes that Support Structures	Strength Limit State	1.5	0.65	1
	Extreme Limit State [a]	1.1	0.9	1

Notes:
a) Does not include liquefaction case – refer to Section 3.2.3

3.4 STABILITY ANALYSIS

An iterative soil-structure interaction (SSI) approach was employed to design the slope stabilization walls. The process integrated geotechnical and structural analyses to achieve a performance-based design under static and CLE loading conditions.

Initial slope stability analyses were conducted to estimate free-field displacements of the 2.15H:1V slope under the CLE. The pseudo-static slope stability analysis and seismic slope displacement calculation were performed using the kh and PGA values presented in Section 3.2.3. A procedure suggested by Macedo et al. (Macedo, 2023) was used to estimate the seismic slope displacement for subduction zone case model resulting in predicted displacements of approximately 0.67 ft.

Following the above, structural modeling was undertaken as detailed in Structural Design Technical Memo (Appendix J). To support this analysis, non-linear p-y curves were developed and provided to the Structural Designers. The p-y curve is a widely used nonlinear analysis method to evaluate the response of laterally loaded piles, where the soil resistance to lateral load is modeled as a series of nonlinear springs. The American Petroleum Institute (API) sand model was chosen for the granular soils. The cohesive soils were modeled using the soft clay (Matlock) and the stiff

clay with free water (Reese) based on the S_u values. These soil models were available in RSPile v.3.031, 2025 software (Rocscience, 2025) and were utilized to generate the p-y curves for the soil type and depth of interest.

The structural engineer's shear resistance output was incorporated into the slope stability model, applying shear resistance perpendicular to the critical slip circle to stabilize the wall. This raised the yield coefficient needed for a safety factor of 1.0 and reduced predicted slope displacement to approximately 0.50 ft (Macedo et al., 2023).

The above analysis was then repeated iteratively until convergence was achieved between the geotechnical and structural models. Final pinned slope displacements were approximately 0.60 ft.

The final global stability (FoS) of the soil mass was confirmed for the static and pseudo static cases with 2D limit-equilibrium analysis (Spencer Method) using Slide2 (Version 9.03) by Rocscience. Stability results are presented below.

Table 3-5
Marine Consortium Global Stability Results

Limit State	Minimum FoS	Design FoS
Strength Limit State	1.5	1.8
Extreme Limit State [a]	1.1	1.1

Notes:
a) Does not include liquefaction case – refer to Section 3.2.3

4.0 BERTHS 306 AND 307

4.1 GENERAL

The slope stability and pile analyses were performed at Berths 306 and 307 to evaluate the performance of proposed pile foundations and adjacent riverbank slopes. The seismic slope deformation and potential requirements for any mitigation such as ground improvement are also presented in this technical memorandum. Note it is the responsibility of the design and build contractor to confirm the requirement for ground improvement as part of the final design.

The analysis outputs presented in this section will be utilized as design inputs for the new Berth and Breasting Dolphin structures presented separately in Structural Design Technical Memorandum (Volume I, Appendix J).

4.2 DESIGN INFORMATION

4.2.1 Slope, Earthwork Geometry, and Pile Foundation

The proposed slope for the new marine structures will be based on the 2.5H:1V gradient (approximately 22˚) at Berth 306 and 307. The rock revetment is considered as the slope protection layer, which consists of 2-ft thick armor stone overlying 1-ft thick bedding stone layer. The granular fill (backfill) material is chosen to fill the gap between the existing ground and the bedding stone layer.

An open-ended steel pipe pile was considered as the proposed foundation with 2.5-ft and 2-ft diameter for Berth (P-R1 to P-R6) and Dolphin structures, respectively. The pile will be driven in a vertical direction for Berth while batter pile with 1H:4V (approximate 14˚) inclination is considered for Dolphin.

4.2.2 Ground Model and Geotechnical Parameter

The stratigraphy is based on relevant subsurface models close to the proposed marine structures: J-J' and K-K' (Figure 2-1k and Figure 2-1l, GDTM). The site-specific geotechnical parameters including the undrained and drained conditions are summarized in **Table 4-1** based on Table 3-1 in the GDTM. The water level considered in the analysis is at elevation +5.1 ft NAVD88, which represents an estimate of low water values reached during low tides during the summer, based on measured Willamette River water levels.

The potentially liquefiable layers were adopted in the slope models based on the liquefaction triggering assessment results at the crest and toe area (Cone Penetration Test and Standard Penetration Test, presented in Attachment B of the GDTM). Residual shear strength of liquefied soil was considered to represent the shear resistance of potentially liquefiable deposits (Idriss and Boulanger, 2008).

The site-specific ground strata with their potentially liquefiable soils for pile analysis are visualized in Figure D-2 to Figure D-5. The summary of input parameters for lateral pile analysis (e.g. ε_{50}, k, and k_{py}) is also provided in Table 4-1. For axial pile analysis, the coefficient of lateral earth pressure (K_δ) of 1 was used for plugged condition assumption and adhesion factor (α) for cohesive soils was estimated based on the S_u values. Other relevant inputs for axial-based analysis including soil-pile friction angle (δ), N_q, and the limit of side and tip unit resistances for granular soil were estimated based on Table 7-8 of the Federal Highway Administration (FHWA) Design and Construction of Driven Pile Foundations – Volume 1 (FHWA, 2016).

Table 4-1
Site-specific Geotechnical Parameters for Slope Stability Assessment and Lateral Pile Analysis at Berth 306 and 307

Engineering Soil Unit	Unit Weight, γ (pcf)	Angle of Internal Friction, φ' (°)	Cohesion, c' (psf)	Undrained Shear Strength, Su (psf)	Strain Factor, ε_{50}	k_{py} Static (pcf)	k_{py} Cylic (pcf)	$k_{\{above\ water\}}$ (pcf)	$k_{\{below\ water\}}$ (pcf)

Post-earthquake condition material									
Residual Shear Strength of Liquefied Soil	110 – 120	-	-	0.13 to 0.16 σ'_v	0.05	-	-	-	-

4.2.3 Imposed Loading

The imposed loading for pile foundation was determined based on the load combination and factors in accordance with LRFD method: ASCE 61-14 (ASCE, 2014) and the LRFD Bridge Design Specification (AASHTO, 2020). The loading condition for pile will be analyzed with the pile resistances computed from this technical memorandum in a separate documentation: Structural Design Technical Memo (Appendix J).

Typical live load surcharges from construction or traffic relevant for slope analysis may be estimated using a surface pressure of 250 psf as per the ODOT Geotechnical Design Manual (ODOT, 2024) and Port of Long Beach Wharf Design Criteria (POLB, 2012).

4.2.4 Horizontal Seismic Coefficient and Peak Ground Velocity

The horizontal seismic coefficient (k_h) and peak ground velocity (PGV) are the inputs to perform pseudo-static slope stability and seismic slope displacement calculation. In accordance with ASCE 7-22, the multi-period response spectra were generated based on the probabilistic seismic hazard analysis conducted in USGS web-based tool (USGS, 2018) for CLE and Design Earthquake (DE), taken as 2/3 of Maximum Considered Earthquake (MCE). The peak ground accelerations (PGA) are 0.23 g and 0.37 g for CLE and DE levels, respectively.

The horizontal seismic coefficient was determined as one-half of the PGA for the hazard level of interest per ASCE 61-14. Thus, k_h values are approximately 0.12 g and 0.19 g for CLE and DE levels, respectively. The PGV of about 9 inches per second (inch/s) (22.5 centimeters [cm]/s) was estimated for CLE while 24 inch/s (60.7 cm/s) was considered for MCE.

4.3 SLOPE STABILITY ANALYSIS

The Berth 306 and 307 riverbank slopes were evaluated based on two selected subsurface sections: J-J' and K-K' in accordance with the procedure provided in ASCE 61-14. The slope stability assessment was performed using the proprietary limit equilibrium software package Rocscience Slide2 v.9.030, 2023 (Rocscience, 2023). The Spencer approach was selected to satisfy both force and moment equilibrium. The circular slip surface was considered to perform the slope assessment.

The pseudo-static slope stability analysis and seismic slope displacement calculation were performed using the k_h and PGV values presented in Section 4.2.4. A procedure was used to estimate the seismic slope displacement for subduction zone case model (Macedo, 2023). The slope analysis results are summarized in **Table 4-2**. The FoS in each considered cross-section and loading case is presented for Berth 306 (K-K') and Berth 307 (J-J') in Figure D-2 to Figure D-5.

The FoS ranges approximately from 1.5 to 1.7 under static condition, which satisfies the minimum FoS requirement. The J-J' slope is observed to be stable (FoS = 1.1) under post-earthquake conditions while ground improvement is needed at the crest and toe of the slope to stabilize K-K' slope or Berth 306 area.

The seismic slope displacement calculation for J-J' slope was then conducted under DE case since the computed FoS is lower than 1.1 for pseudo-static case, which informed free-field lateral movement at about 1.1 ft. Considering the ground improvement installed at the crest and toe area

of K-K' slope, the estimated FoS was observed to be lower than 1.1 for both design earthquake levels. The corresponding seismic slope displacements were estimated at approximately 0.33 ft and 1.2 ft under CLE and DE, respectively. The presence of ground improvement at Slope K-K' (Berth 306 area) reduced the estimated seismic slope displacement by approximately 40 to 50 percent under pseudo-static case while this effect was insignificant for the computed FoS values.

Table 4-2
Summary of the Factor of Safety and Estimated Seismic Slope Displacement at Berth 306 and 307 Slopes

Slope/ Subsurface Section	FoS Static		FoS Post-Earthquake		FoS Pseudo-static (CLE and DE)		Pseudo-static Slope Displacement (CLE and DE)	
	Short-term	Long-term	No Ground Improvement	With Ground Improvement	No Ground Improvement	With Ground Improvement	No Ground Improvement	With Ground Improvement
K-K' Berth 306	1.5	1.55	0.75	1.1	0.96 and 0.81	1.05 and 0.85	0.56 ft and 2.5 ft (17 cm and 75 cm)	0.33 ft and 1.2 ft (10 cm and 36 cm)
J-J' Berth 307	1.66	1.66	1.1	-	1.1 and 0.88	-	1.1 ft for DE (33 cm for DE)	-

4.4 LATERAL PILE ANALYSIS

The p-y curve is a widely used nonlinear analysis method to evaluate the response of laterally loaded piles, where the soil resistance to lateral load is modeled as a series of nonlinear springs. The API sand model was chosen for the granular soils. The cohesive soils were modeled using the soft clay (Matlock) and the stiff clay with free water (Reese) based on the S_u values. The hybrid liquefied sand model (Franke and Rollins, 2013) was considered to model the potentially liquefiable soils. These soil models were available and implemented in RSPile v.3.031, 2025 software (Rocscience, 2025) to generate the p-y curves for the soil type and depth of interest.

The site-specific ground profiles were developed for lateral pile analysis with geotechnical parameters summarized in Table 4-1. The site-specific ground strata are presented in Figure D-2 to Figure D-3 which are also used for axial resistance calculation presented in the next section (Section 4.5). The lateral resistance of single pile in the slope was then scaled with the p-multipliers to account relation between lateral resistance and the slope angle (sloping ground effect) (Reese and Van Impe, 2011). The p-multipliers for pile in the sloping ground with a gradient of 2.5H:1V (approximately 22˚) are 0.5 for out of slope direction and 1.8 for into slope direction.

The group p-multiplier method (Hannigan et al., 2006) was implemented to estimate the reduction in lateral resistance due to group pile effect with center-to-center (CTC) spacings equal and less than 5B. Linear interpolation is allowed for CTC pile spacing case between 3B and 5B. The structural engineers may adjust the single pile p-y curves with the p-multipliers suggested per **Table 4-3** to account for the group pile configuration.

The p-y curves have been prepared for the structural engineers considering the proposed pile information provided in Section 4.2.1 to further evaluate the lateral performance of the structures. The detail of structural analysis output is presented in Attachment J.

Table 4-3
Pile p-multipliers (Pm) for Multiple Row Shading per FHWA/AASHTO

Pile CTC spacing (in the direction of loading)	p-multipliers, P_m		
	Row 1 (Lead Row)	Row 2	Row 3 and higher
3B	0.8	0.4	0.3
5B	1.0	0.85	0.7

4.5 GEOTECHNICAL AXIAL PILE RESISTANCE

The axial resistance of piles was calculated based on the procedure suggested in P2A Method-Mixed Soil Profiles (FHWA, 2016). This method is based on API for offshore steel pipe pile foundation. The calculation was performed with the assumptions of plugged condition achieved at the pile tip and without group pile effect since the pile spacing was greater than 3B.

The estimated axial pile resistances for the proposed pile foundations are presented with the corresponding site-specific ground strata in Figure D-4 to Figure D-10. Each figure presents both nominal (unfactored) and factored axial resistance profiles under strength limit and extreme limit events. The resistance factors were determined as suggested per the API method, which gave values of 0.65 for compression and 0.5 for tension assuming dynamic field-testing consideration for strength limit event (AASHTO, 2020). For extreme limit event, resistance factors of 1 and 0.8 are allowed for compression and tension, respectively.

The side resistance above the neutral axis identified within the potentially liquefiable deposit was neglected for the axial resistance calculation during extreme limit event. This assumes that the surface manifestation occurs due to insufficient layer thickness of overlying non-liquefied soil.

4.6 SETTLEMENT INDUCED DOWNDRAG LOADS

Downdrag is a phenomenon when a pile or pile-group is imposed to negative (downward) side shear stresses manifested in the ground surrounding the pile length when settling more than the pile. The downdrag loads were estimated based on the presence of consolidating soils (compressible soils) and potentially liquefiable soils identified along the pile length. The negative skin friction for liquefiable soil was calculated using the residual shear strength of liquefied soil ratio suggested per Section 4.2.2, which gave approximately 40 to 50 percent of the positive skin friction, consistent with the conclusion of a full-scale test study (NCHRP, 2019). The consolidation and liquefaction induced downdrag loads calculated for Berth P-R1 to P-R6 and Dolphin piles are tabulated in Table 4-4.

Table 4-4
Consolidation and Liquefaction Induced Downdrag Loads

Pile	Ground Surface Elevation (ft NAVD88)	Consolidation Case		Liquefaction Case	
		Depth to bottom of compressible layer (ft bgs)	Consolidation induced downdrag (kips)	Depth to bottom of potentially liquefiable layer (ft bgs)	Liquefaction induced downdrag (kips)
P-R1	28	55	405	49	210
P-R2	25	52	380	46	185
P-R3	13.5	43	225	79	270
P-R4	3	32	140	68	230
P-R5	-8	21	75	57	145
P-R6	-15	14	40	50	115
Dolphin	-15	14	40	50	245

5.0 FURTHER DESIGN AND CONSTRUCTION CONSIDERATIONS

The above design recommendations are based on the current scope of field investigation and available project details at the time of writing. It is anticipated that further geotechnical design will be carried out by the appointed design and build contractor.

It is recommended that the design and build team undertake:

- Additional site-specific investigations as required to confirm key geotechnical parameters;
- Finalization of design in accordance with applicable codes, standards, and project specifications; and
- Drivability assessment as part of the detailed design; where dense soils or obstructions are encountered, pre-drilling may be required to facilitate pile installation.

Assumed subsurface profile based on Soil Profile J-J'. At this design stage the Qf-Sand (SM) layer is assumed to extend below the bottom of the ground investigation data. Additional ground investigation data will likely be required to support final design. The scope and type of subsurface data required to complete the final design should be determined by the design-build contractor.

- Nominal Skin Resistance
- Nominal Base Resistance
- Factored Total Resistance (Compression)
- Factored Total Resistance (Uplift)

Notes:

Axial resistance values are based on preliminary foundation design developed to a 30% level in the 90% RD (refer to Structural Design Technical Memorandum – Appendix H) . Final design will be completed by the contracted Final Designer under a performance-based model.

Axial resistance of piles calculated per FHWA (2016), Design and Construction of Driven Pile Foundations – Volume 1.

Calculated axial resistance applies to single piles only; group effects not considered for piles spaced <3.0 diameters (center-to-center).

Factored total pile resistance shown on plots combines unfactored side and base resistances, multiplied by resistance factors:

- Strength limit state: 0.65 (compression), 0.5 (tension), assuming dynamic testing on ≥2% of production piles (Table 7-2, FHWA 2016).

- Extreme event limit: 1.0 (compression), 0.8 (tension), per AASHTO LRFD Bridge Design Spec (2020, Sec. 10.5.5.3.3).

Refer to Geotechnical Design Technical Memorandum, Attachment D, Table 4-4 for estimated consolidation and liquefaction induced down-drag loads.

ATTACHMENT E
EXISTING MARINE STRUCTURES (PIER A AND QUAY WALL)

1.0 INTRODUCTION AND HISTORICAL BACKGROUND

The following attachment summarizes the stability and geotechnical analysis of the Pier A (also referred to as Berth 301) and the Quay Wall design area. The analysis presented herein was completed for the existing conditions and towards the 90% remedial design (RD). The purpose of this study is to examine the failure modes and document the analysis for the existing condition and the proposed solutions.

1.1 HISTORICAL BACKGROUND

Pier A was constructed in the mid-1940s and originally consisted of 28 diaphragm cells. However, the final structure included 20 diaphragm cells, 3 circular cells, and 1 closure steel sheet pile cell. During construction, eight diaphragm cells failed due to base failures caused by sliding and piping, which resulted from excessive hydrostatic head and impaired drainage during the hydraulic placement of fill material. These failures were documented in the "Swan Island, Dry Dock Basin, Foundation Failure" report. Consequently, the eight failed diaphragm cells were replaced with three circular cells and one closure steel sheet pile cell (CH2M Hill, 1975).

Variability was noted in the characteristics of the artificial fill depending on the method used and the variability is attributed to different methods used for placing the artificial fill, namely: the hydraulic method and the clamshell bucket and back dumping method. Additionally, the fill material might not have been properly compacted, leading to the presence of looser soil zones (CH2M Hill, 1975).

The failure and collapse were concluded as due to the splitting of the cell and the release of hoop pressure. The failure and collapse took place entirely above the mud line through a vertical split in the cell. No interlock failures occurred, although one tear was observed below the waterline. Additionally, several tears resulting from the bullrail collapse were observed above the waterline. The tear in the collapsed cell was identified at the welded connection between the base sheet and the outstanding leg of the connecting tee piece (CH2M Hill, 1975).

A metallurgical investigation was conducted as part of the 1975 failure investigation. The results indicated that the tear in the connecting tee was caused by poor penetration and fusion during the welding process. Conceptually, the internal failure process was interpreted to consist of several steps: (1) preexisting crack, (2) corrosion, (3) stress concentration, (4) crack propagation, and (5) further corrosion. These factors collectively reduced the section area to a level that could not support the design loads, ultimately leading to total failure (CH2M Hill, 1975).

The study analysed the effects of dredging at Pier A for feasibility purposes. Key findings include:

- **Dredging not recommended** riverward of the circular sheet pile cells at Pier A.
- **Dredge line** should stay at elevation -30 ± (SISRY datum) along the diaphragm cells.
- **Feasibility** of dredging in Berth 301 (diaphragm cells) if a 3H:1V slope is maintained.
- **Slope protection** with riprap recommended to prevent erosion and adverse conditions.
- **Drydock support** in Berth 301 should be supported independently of the diaphragm cells.

1.1.1 Pier A

The RD for the Swan Island Basin (SIB) Project Area is within the Portland Harbor Superfund Site in Portland, Multnomah County, Oregon. The Pier A design area, (Figure 1-1, Plan Area 7 and partial Plan Area 8) is located to the west of the Port of Portland Berth 302 (Lagoon Wharf, Partial Plan Area 8). Pier A was also referred to as Berth 301 in the 1975 and 1981 dated historical reports (#SR SI 1975 0026 00 and #SR SI 1981 0041 00). Pier A was built in 1944 and 1945 and is constructed of 20 diaphragm cells, 3 circular cells, and 1 closure steel sheet pile cell. The width of the Pier A structure is approximately 52 feet (ft) from the stations 52+00 to 43+00. The sheet piles are approximately 105 ft long and embedded to the elevation of -68 on the waterfront side, and approximately 87 ft long, embedded to elevation of -55 on the landward side of the Pier A.

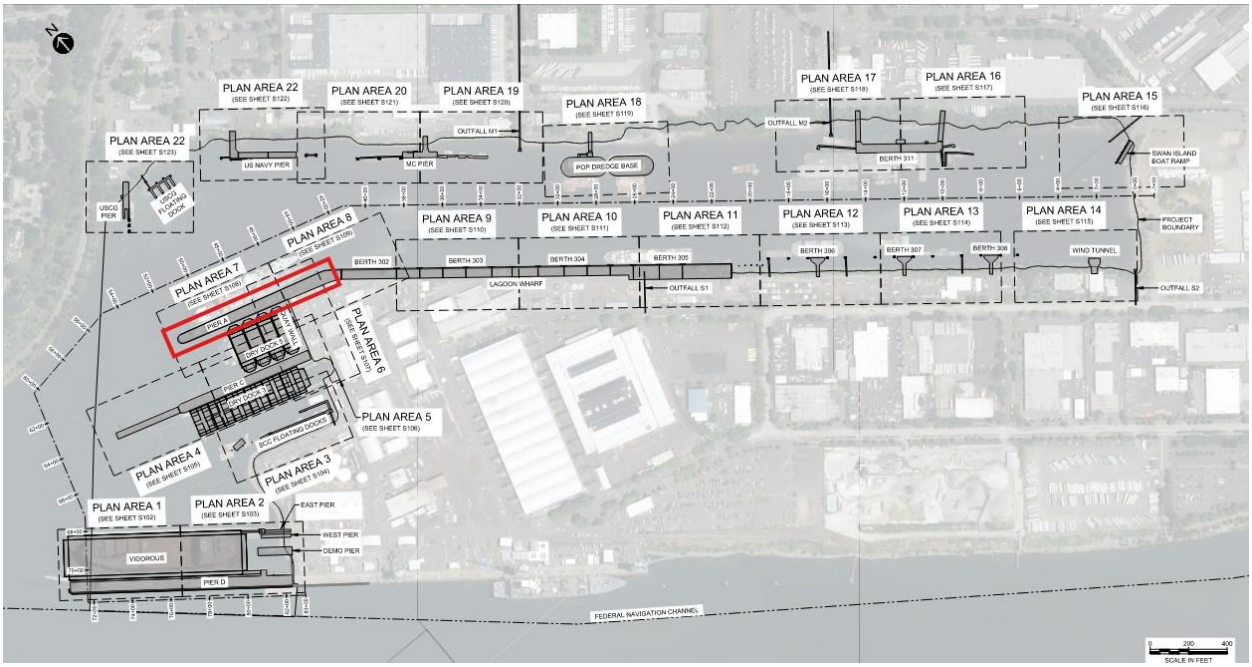

Figure 1-1 Pier A Layout

1.1.2 Quay Wall

The Quay Wall design area, (Figure 1-2, Plan Area 6) is located between the span of Pier A and Pier C. The Quay wall (also referred to as Dry Dock 5) is an earth-retaining structure and consists of a series of nine circular steel sheet pile cells with connecting arcs, one steel sheet pile closure cell, one diaphragm wall, and a section of anchored steel sheet pile bulkhead. The circular sheet cells are constructed of 172 pieces of SP-6 flat-web interlocking sheet piling (15 inch [in] wide with a 3/8 in thick web) with a diameter of 68.42 ft. The sheet piles are approximately 105 ft long and consist of two sheets spliced together with a steel plate and bolts. The splice is generally between the elevation -20 ft and elevation -35 ft. The structure lies between the stations 61+00 to 63+00.

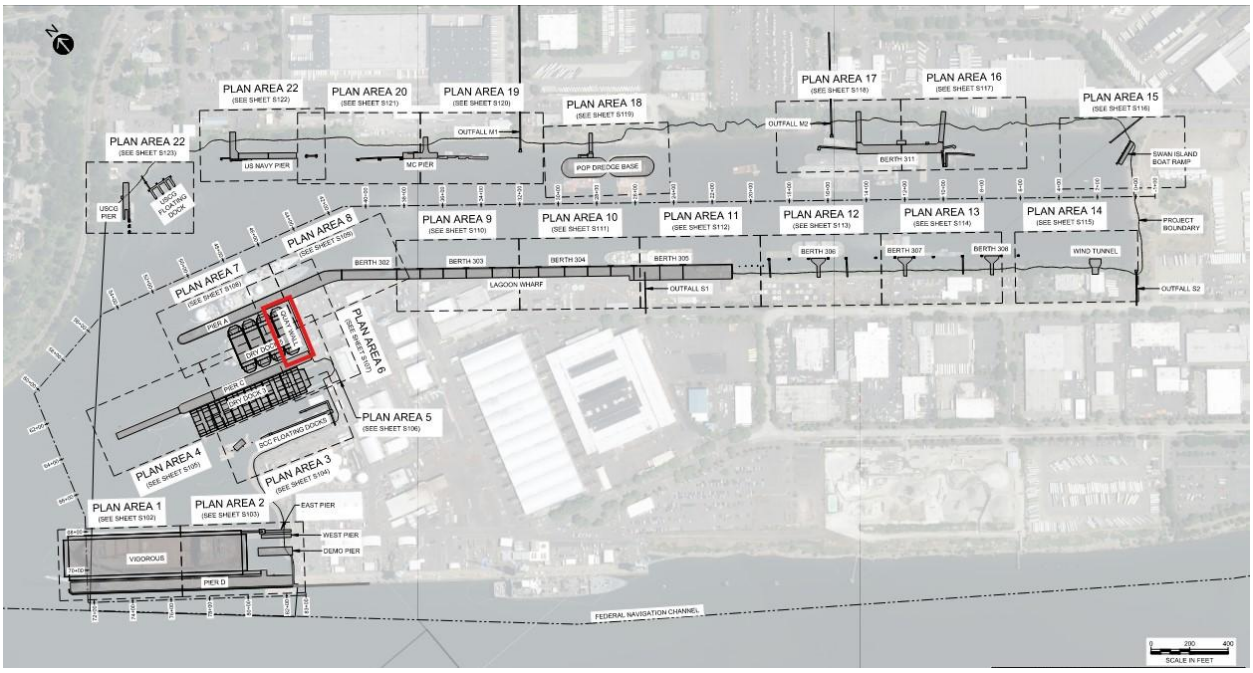

Figure 1-2 Quay Wall Layout

2.0 ANALYSIS METHODOLOGY

The objective of the analyses carried out for this study is to assess the stability of Pier A and the Quay Wall. The procedure taken to achieve this is as follows:

1) Review Foundation Failure Report (CH2M Hill, 1975) and reproduce safety factors for various failure modes associated with the static existing conditions.
    a. Leverage more modern analytical techniques where possible.
    b. Include sensitivity cases to address uncertainty in the engineering soil parameters.
2) Carry out additional analyses of the existing condition which consider the dynamic thrust from the Contingency Level Earthquake (CLE). These are used to verify the overall adequacy of the systems in the existing condition.
    a. Preliminary analyses suggest that both systems are adequate in the existing condition, so long as the structural integrity of the walls have not been compromised (i.e. properly installed/maintained welds, etc.).
3) Optimize revetment geometries which enable deeper dredge depths to some distance from the face of the cells but preserve the stress states adjacent to the walls.
    a. Requires estimation of back of wall pressures before and after implementing proposed revetment solutions.
    b. Facilitated with the implicit Finite Element software Plaxis 2D (v 2024.2 by Bentley).

2.1 SCOPE

The primary goal of the analyses discussed herein is to assess the existing stability of the Pier A and Quay Wall structures under static, CLE, and post-seismic conditions. Furthermore, the analysis models developed for this purpose are also leveraged to optimize revetment solutions which will enable as much dry dock working area as possible through additional dredging without compromising stability. Failure modes of concern for structures such as these include bearing capacity, interlock splitting, internal shear, foundation sliding, and overturning. While interlock failure was found to be the governing Factor of Safety (FoS) in the existing condition, bearing capacity is observed to be the most sensitive failure mode to the effects of additional dredging. The mode of failures and limit equilibrium calculation approaches are presented in Section 2.7.

2.2 GEOMETRY

2.2.1 Pier A

The crest of the riverbank varies between elevations of -35 to -40 ft North American Vertical Datum of 1988 (NAVD88). Pier A is supported by steel sheet piles, ranging from 36 ft to -68 ft in height towards the river. Similarly, towards the landward the piles range from 36 ft to -55 ft high. The water level considered in the model is at the elevation +5.1 ft NAVD 88, which represents an estimate of low water values reached during low tides during the summer, based on measured Willamette River water levels.

2.2.2 Quay Wall

Each cell of the Quay Wall consists of interlocking steel sheet piles driven into the riverbed in a circular configuration, typically measuring approximately 60 ft in diameter. The sheet piles extend to depths of about 70 to 80 ft below the top of the wall, depending on the riverbed elevation and the required embedment for stability. The exposed height of the cells, from the dredged riverbed to the working surface, is generally between 40 and 50 ft.

2.3 GROUND MODEL AND GEOTECHNICAL PARAMETERS

The Pier A and Quay Wall project site comprises of a simplified ground model. Both these structures consist of circular cellular cofferdams. The fill material inside these cells is referred to as ‘cofferdam fill’ and exists from +36 ft NAVD88 to an approximate depth of -68 ft (riverward) and -55 ft (landward). An alluvium layer consisting of sand underlying the cofferdam fill and the dredge surface is observed to extend up to approximately 20 to 30 ft deep. The water level considered in the model is at the elevation +5.1 ft NAVD 88.

The ground model implemented in the finite element analysis (FEA) is based on the soil stratigraphy obtained from the geotechnical field investigations at the project site. Figure 2-1 presents the geotechnical section N-N` from the Geotechnical Design Technical Memorandum (GDTM).

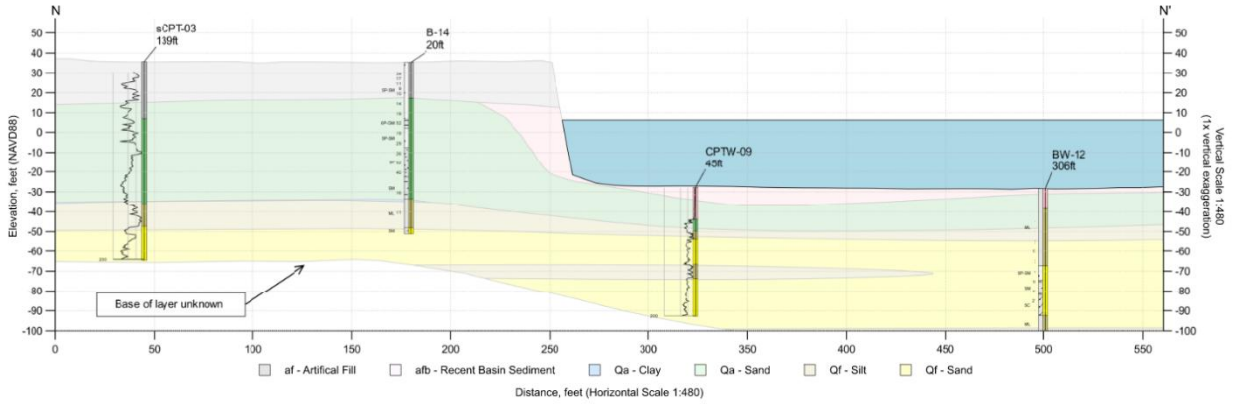

Figure 2-1 Geotechnical section showing the stratification for Pier A and Quay Wall

The baseline soil properties and material models implemented in the Finite Element (FE) models are presented in **Table 2-1**.

Table 2-1
Soil Material and Properties Implemented in FEA

Rip Rap	MC	1.0	44	140.0	3.13E+06	0.30	-

Notes:
[1] MC: Mohr-Coulomb Model
[2] Critical State Friction Angle

2.3.1 Seismic Parameters

Since no new structures are to be built to satisfy the Remedial Action (RA) for Pier A and/or the Quay Wall, the only seismic shaking demand considered herein is the CLE (i.e. the systems may not remain operational after a 475-year event).

The CLE is defined as a seismic event associated with a 475-year return period. This corresponds to a peak ground acceleration (PGA) of 0.23g, according to the U.S. Geological Survey (USGS) hazard tool. This was implemented in a pseudo-static fashion in Plaxis 2D using a horizontal acceleration factor k_h = 50% PGA (ODOT, 2024; AASHTO, 2020).

2.3.2 Post-Seismic Liquefaction Parameters

Triggering assessments based on the assumed ground parameters and CLE demands suggest that the Pier A and Quay Wall cellular cofferdam backfill material may liquefy during a CLE seismic event. Screening level 2D FEA was carried out assuming material within the cells liquefied with a resulting vertical stress ratio of 20 percent. Based on the assumed ground parameters, CLE demands, and liquefied cellular cofferdam backfill material, the 2D FEA results indicate a FoS of greater than 1.1 at both Pier A and Quay Wall. Considering the screening analysis results, no additional analyses considering liquefied cellular cofferdam backfill material were carried out.

2.4 SENSTIVITY STUDIES ON EXISTING CONDITION

To observe the influence of soil property variations on the stability and performance of the Pier A structure, a comprehensive parametric analysis was undertaken.

The soil properties used for the parametric study with 15% increased and 10% decreased soil parameters analysis are given in Table 2-2 and Table 2-3, respectively.

2.5 REVETMENT GEOMETRY OPTIMIZATION

To develop an efficient and stable revetment configuration for Pier A, a series of design iterations were conducted using the existing 2D Plaxis model (refer to Figure 2-2). The primary objective was to identify the minimum revetment lengths that would maintain structural stability while maximizing the available dry dock working area through additional dredging. These iterations focused on optimizing the geometry of riprap buttressing on both the north (riverward) and south (landward) sides of Pier A, without altering the structural configuration of the pier itself.

Each optimization trial involved systematic adjustments to the revetment lengths and, in some cases, the slope geometry. The performance of each configuration was evaluated based on the resulting back-of-wall pressures, which served as an evaluation for structural demand and overall stability.

2.5.1 Summary of Trial Geometries

For each successful baseline trial listed below (i.e. all except trial 3), 100 stochastic iterations were carried out in an automated fashion, assuming coefficients of variation of 5% for listed mean/baseline geometric parameters and 25% on engineering soil parameters. The commentary on resulting back-of-wall pressures in the list below only pertain to the mean/baseline values for each optimization trial. While back-of-wall pressures did vary slightly between stochastic runs associated with the same baseline trial, stability was checked and found to be adequate for all

iterations except those associated with trial 3. In total, 500 of the attempted 600 Plaxis 2D simulations were carried out to completion as part of this optimization exercise.

1) Trial 1:

   Note: For Trials 1 to 4, top of revetment was modeled horizontally to match the historic mudline at -42 ft elevation.

   a. Baseline configuration with 30 ft (north) and 15 ft (south) revetment lengths.
   b. Slopes of 20.7° (north) and 31° (south).
   c. Back-of-wall pressures: -3463 lbf/ft² (north), -4292 lbf/ft² (south).

2) Trial 2:

   a. Revetment lengths: reduced north revetment to 22 ft; south remained at 15 ft.
   b. Slopes unchanged.
   c. Back-of-wall pressures: -3352 lbf/ft² (north), -3710 lbf/ft² (south).

3) Trial 3:

   a. Revetment lengths: reduced north revetment to 17 ft; south remained at 13 ft.
   b. Slopes unchanged.
   c. Model failed to converge due to instability.

4) Trial 4:

   a. Revetment lengths: increased north revetment to 20 ft; south remained at 15 ft.
   b. Slopes unchanged.
   c. Back-of-wall pressures: -3974 lbf/ft² (north), -3770 lbf/ft² (south).

5) Trial 5:

   Note: Trials 5 and 6 introduced a sloped transition at the top of the revetment to evaluate its influence on wall pressures. However, these modifications did not yield significant changes in the pressures.

   a. Revetment lengths: 20.1 ft (north), 15 ft (south)
   b. Slopes: 20.7° (north) and 31° (south) from historic mudline to dredge depth; 4.7° slope added at the top of the north revetment.
   c. Back-of-wall pressures: -3945 lbf/ft² (north), -3740 lbf/ft² (south).

6) Trial 6:

   a. Revetment lengths: 20.5 ft (north), 15 ft (south).
   b. Slopes: 20.7° (north) and 31° (south) from historic mudline to dredge depth; 13.1° slope added at the top of the north revetment.
   c. Back-of-wall pressures: -3874 lbf/ft² (north), -3592 lbf/ft² (south).

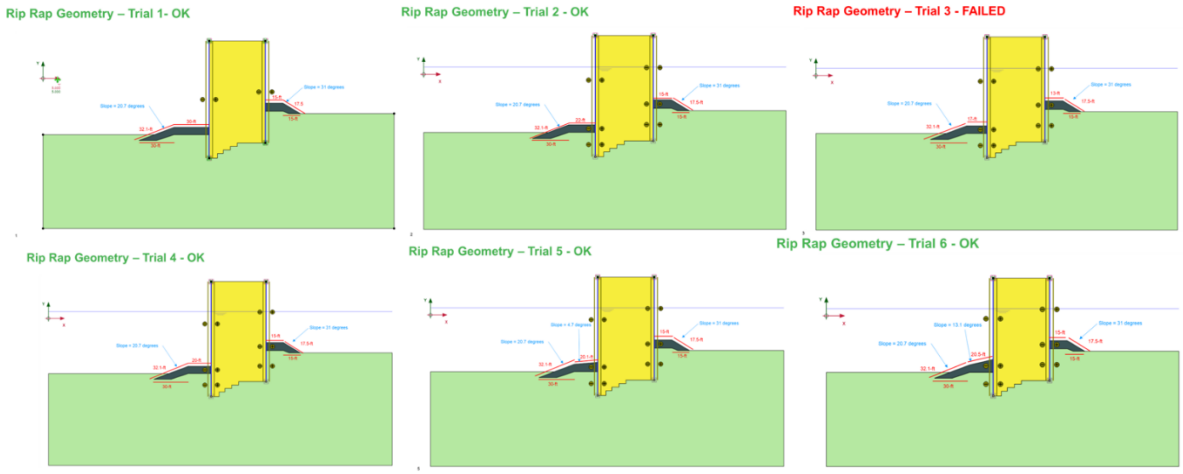

Figure 2-2 Range of revetment solutions considered

2.5.2 Conclusion and Final Optimized Geometry

Based on the comparative performance of all configurations, Trial 4 was adopted as the final design. This geometry offers a balance between structural stability, maximum dry dock, and material efficiency. The optimized revetment geometry consists of a 20 ft length on the north side and 15 ft on the south side, with slopes of 20.7° and 31°, respectively.

The revetment design for the Quay Wall was subsequently developed based on optimized geometry from the Pier A analysis.

2.6 STRUCTURAL ELEMENTS PROPERTIES

Initially, closed form solutions were carried out to determine the factors of safety against the failure modes defined in the next section. The outcome of that exercise confirmed the findings from the historical report (CH2M Hill) for the static condition and provided the first quantitative indication that the system is acceptable stable under CLE demands. With this knowledge, revetment geometries were then optimized to enable deeper dredge depths some distance away from the cell walls by ensuring the stress state on the inside of the wall did not change in an unfavorable way as a result of installing the revetment. Since this framework only requires models to capture internal wall pressures (as opposed to accurate global factors of safety), simplifications were made to expedite model development and run time. One of these pertains to the cell walls, which were modeled as rigid to ensure conservative estimates of back of wall pressures. The Figure 2-3 below illustrates the nature of the structural aspects of the model.

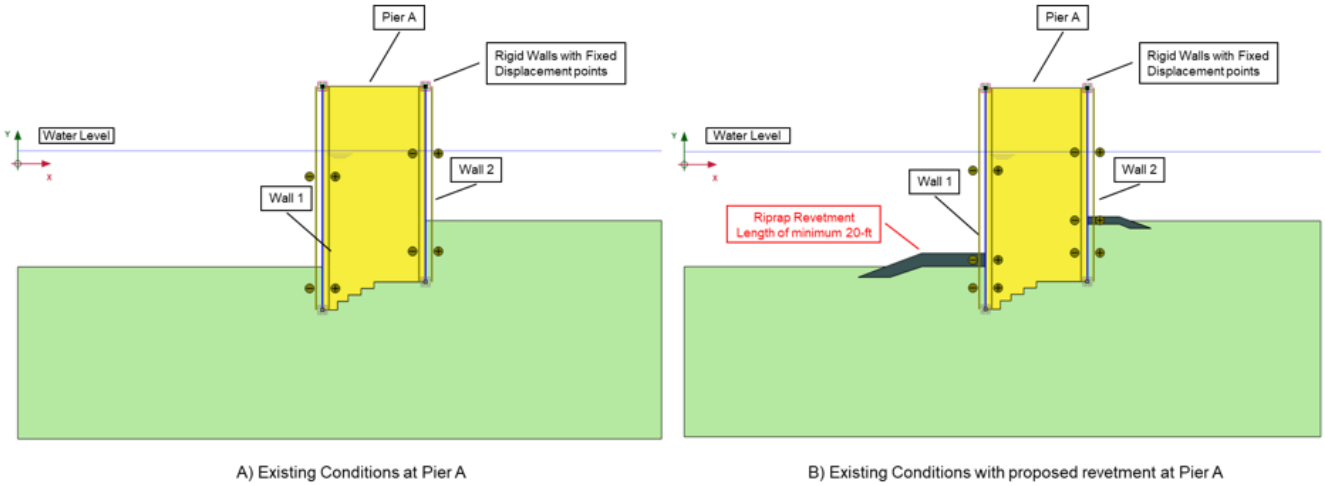

Figure 2-3 Structural Elements for Pier A

2.7 LIMIT STATES

Due to the complex interactions between cellular cofferdam geometry, sheet piles, and cell fill, there are no theoretical solutions for these FoS. The analysis might be further complicated due to fluctuation of water levels and the possibility of flooding in river environments. Thus, cofferdam design relies on semi-empirical methods, with three main approaches having a history of reasonable success: (1) Former Tennessee Valley Authority (TVA) methods (a.k.a., Terzaghi's method), (2) Cummings method, and (3) Hansen's (Danish) method. The current study followed TVA Method (Terzaghi's Method) for semi-empirical approach (Bowles, 1997).

Based on the TVA Method, the following internal and external FoS checks for cofferdams are recommended for limit state calculations for stability and design of a cofferdam (Bowles 1997; U.S. Army Corps of Engineers, Engineering Manual 1110-2-2503):

(a) Cell sliding (external stability)
(b) Cell overturning (external stability)
(c) Cell bursting (internal stability)
(d) Cell shear along the centerline (internal stability)
(e) Bearing capacity and settlement (external stability)

Figure 2-4 shows the failure modes and Figure 2-5 shows the pressure profile and terminology used for the dimensions.

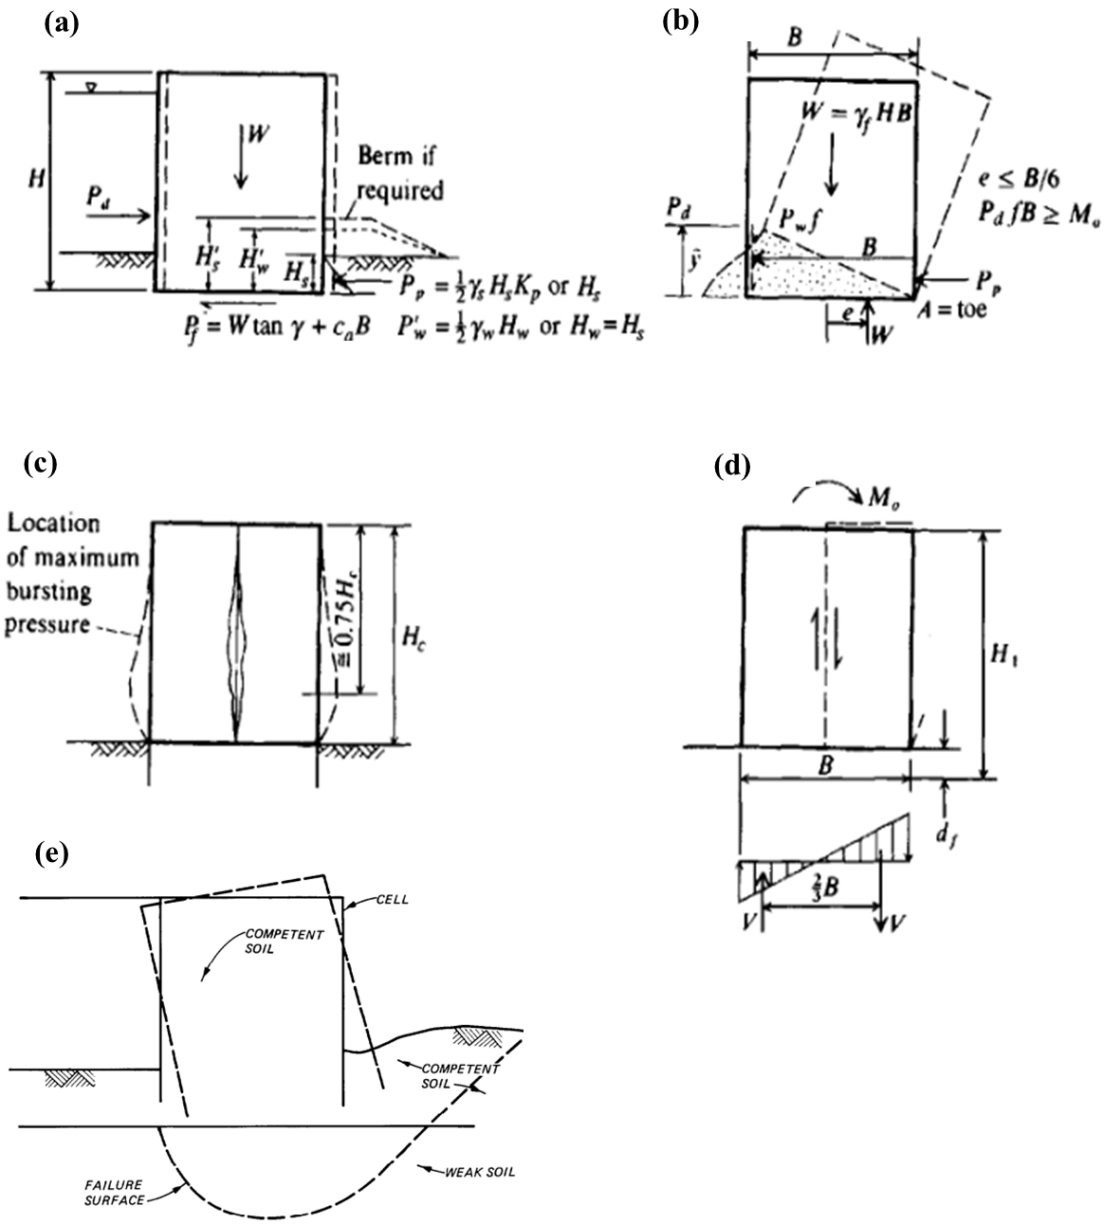

Figure 2-4 External (a) sliding, (b) overturning, and internal (c) interlock tension (d) shear (After Bowles, 1996) and external (e) bearing capacity (After USACE, 1989) failure modes considered for Pier A and Quay Wall structures

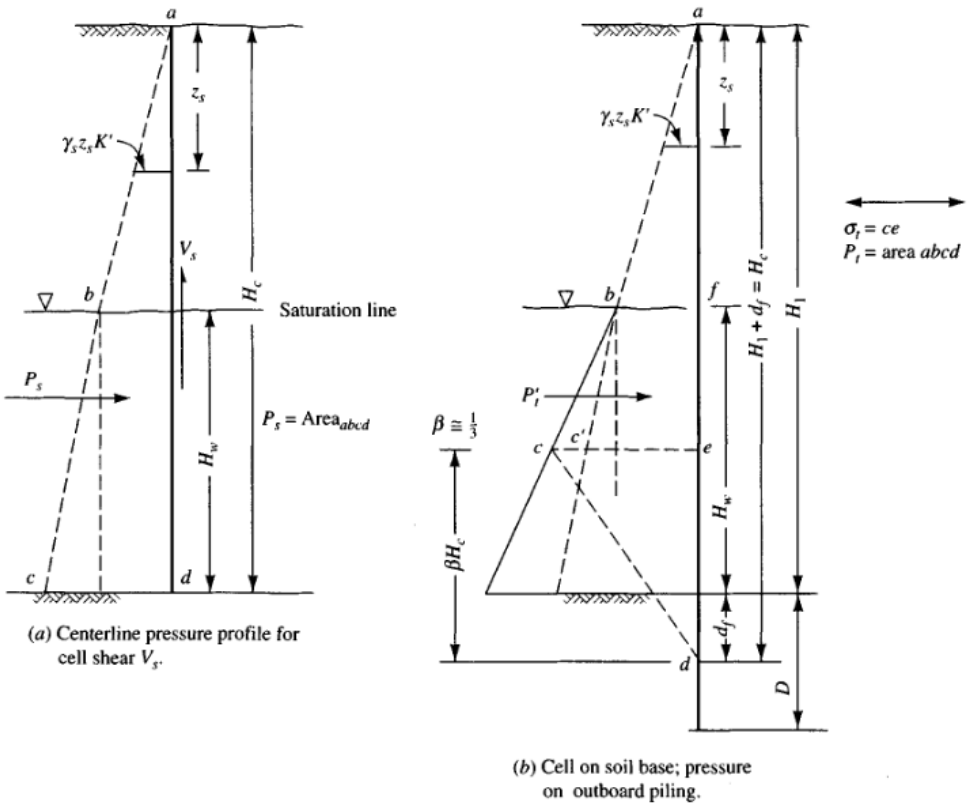

Figure 2-5 Pressure profiles for centerline shear, interlock friction and interlock tension (After Bowles, 1996)

For Pier A and Quay Wall structures, the recommended internal (i.e. cell bursting and cell shear) and external failure (i.e. cell sliding, cell overturning and bearing capacity) modes were investigated. The results are compared with the factor of safety results given in 1975 dated CH2M Hill report (Roth and Ramage, 1975) and presented in Section 3.0.

2.7.1 Cell Sliding Failure

It is essential to consider the structural behavior, how compressive and shearing loads are transmitted to the foundation, the foundation's response to these loads, and the secondary effects on the structure to properly assess sliding stability. As an external failure analysis, sliding is grounded in the principles of structural and geotechnical mechanics.

In this analysis, only force equilibrium is considered, and moment equilibrium is not applied. The shearing force parallel to the interface of any two wedges is assumed to be negligible. Therefore, the failure surface at the bottom of each wedge is influenced only by the forces directly above or below it, with no vertical interaction between wedges. Displacement considerations are excluded in the limit equilibrium approach (USACE, 1989).

Based on horizontal forces applied to the section, sliding stability number, N_s, is calculated as follows (Bowles 1996):

$$N_s = \frac{P_p + P_f + P'_w}{P_d + P_a} > 1.10 \quad \text{(Eq.1)}$$

$$P_f = W\ tan\delta + c_a\ B \quad \text{(Eq.2)}$$

$$P_d = P_w = \frac{1}{2}\ \gamma_w\ H_w^2 \quad \text{(Eq.3)}$$

$$P_p = \frac{1}{2}\ \gamma'_s\ H_s^2 K_P \quad \text{(Eq.4)}$$

$$P_a = \frac{1}{2}\ \gamma'_s\ D^2 K_a \quad \text{(Eq.5)}$$

$$P'_w = \frac{1}{2}\ \gamma_w\ H'^2_w \quad \text{(Eq.6)}$$

where, P_p is passive resistance, P_f is friction on base, P'_w is berm water force, H'_w is the water depth on basin side, and, P_d is driving force which is generally outside water (P_w) (Figure 2-4[a]). In Eq. (1) active earth force, P_a , is neglected unless the embedment depth, D, is more than about 5.74 ft.

2.7.2 Cell Overturning Failure

Cofferdams, as a soil-filled cellular structure are not rigid gravity structures prone to overturning at the toe of the inboard side. Overturning would only occur after failures like sheet pile pullout at the heel and loss of cell fill. However, a gravity-block analysis can help determine the necessary cell diameter. Since the cell fill cannot resist tension, the cell should be designed so that the resultant forces fall within the middle third of the equivalent rectangular (Figure 2-6) base (USACE, 1989). To prevent overturning, and considering that soil cannot withstand tension forces, the resultant weight, W, should be positioned within the middle one-third of the base (Figure **2-**2-4[b]).

$$e = \frac{P_d\,\bar{y}}{\gamma HB} \quad \text{(Eq.7)}$$

As the second possibility, in case, the cell tip over and the soil will pour out at the heel, the friction resistance between the cell fill and the water-side sheet-piling must develop from the water force $P_d = P_w$. Required average cell width, B, can be calculated from the total moment about the toe of the cell (Figure 2-[b]).

$$B = \frac{\bar{y}}{\tan\delta} \quad \text{(Eq.8)}$$

where is the angle of friction between cell fill and steel and may be estimated at about 0.6 to 0.70 Ø. Depends on the size of the embedment depth, the active and passive soil pressures (Figure 2-7) on the overturning moment and friction resistance should be included to total moment about point A in Eq. (8).

The stability number for overturning, N_{ot}, is calculated as follows:

$$N_{ot} = \frac{B \tan\delta}{\bar{y}} \qquad \text{(Eq.9)}$$

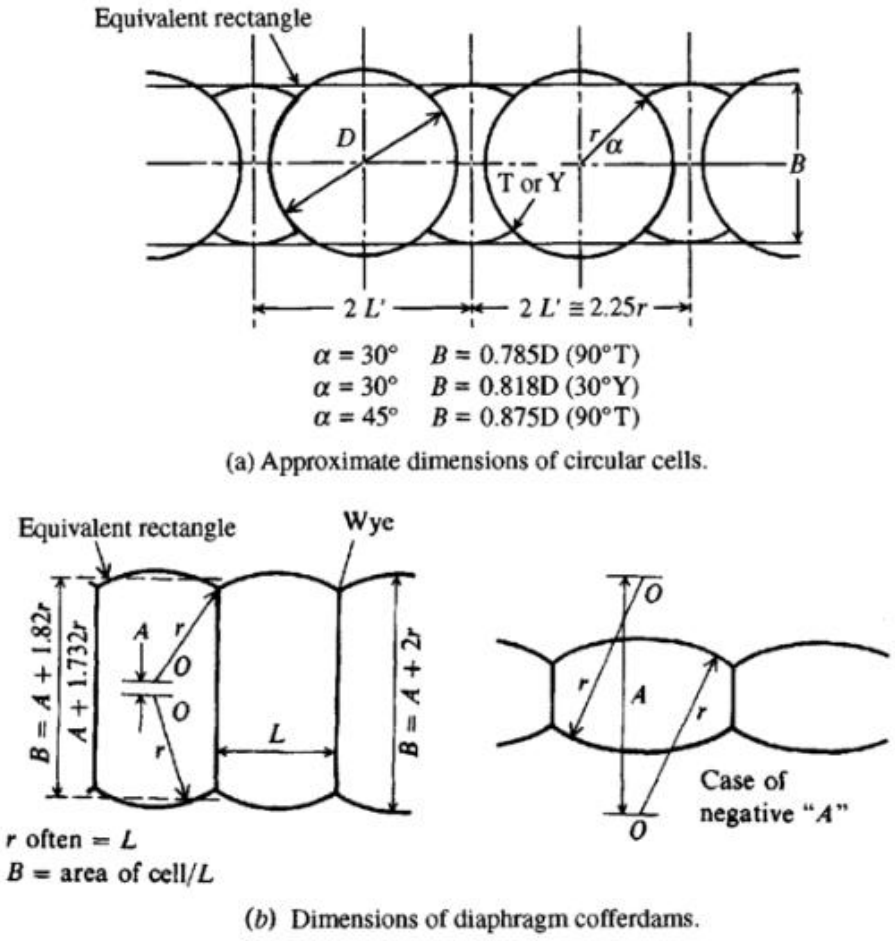

Figure 2-6 Equivalent rectangle dimensions for (a) circular cells and (b) diaphragm cofferdams (Bowles, 1996)

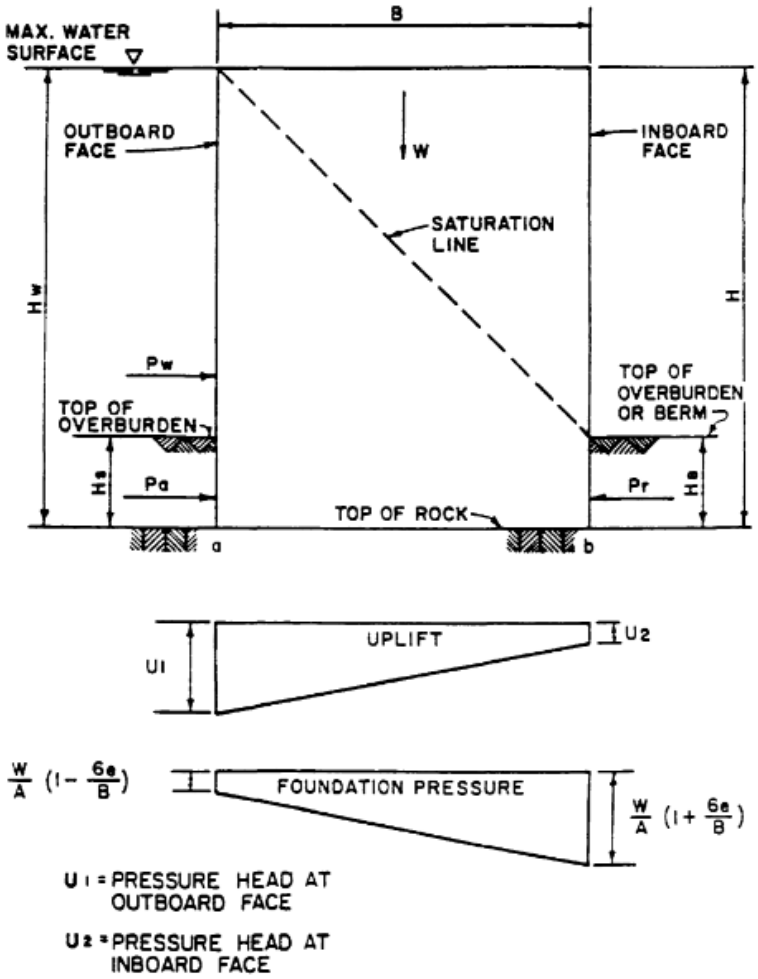

Figure 2-7 Typical loading and nomenclature for overturning stability of cells (USACE, 1989)

2.7.3 Cell Bursting- Sheet Pile Interlock Tension Failure

Cofferdam cells must be stable against bursting pressures, which can cause the piles to pull apart at the joints. During filling, lateral pressures develop and increase over about 10 days as the fill consolidates. The cell expands in response to these pressures, with the extent of expansion depending on whether the base is restrained by rock or embedded in the ground. The expanded cell takes on a bulged shape, most pronounced at one-fifth to one-third of the cell's free height above the dredge line or rock.

The point corresponds to $H_c/4$ (Figure **2**-2-4[c] and Figure 2-5) for cells is most critical for interlock tension evaluation. Maitland and Schroeder (1979) suggest finding this point as one-third of the modified cell height, H, based on the depth of fixity, d_f, below the dredge line when the cell is embedded in soil.

Estimated point of fixity in sand as the point of zero pressure and zero deflection is computed following equations (Eq.s 9 and 10). If the dredge line soil has $\emptyset = 0$, a depth of fixity (d_f) value between 1 and 1.65ft is recommended (Bowles, 1996).

$$H_1 = H_c + d_f \quad \text{(Eq.9)}$$

$$d_f = \frac{P_a}{\gamma'(K_p - K_a)} \quad \text{(Eq.10)}$$

Where, $H_c$is free cell height (Figure 2-5[b]), γ' is effective unit weight below the outside dredge line, K_o is passive and K_a active Rankine earth pressure coefficients for the soil below the dredge line.

The depth of $H_c/4$ (Figure 2-5[b]) can be used to estimate the lateral subgrade modulus in the embedded part of the pile. This estimation is generally as accurate as using and γ. The design results are similar whether $H_c/4$ or $H_c/3$ is used or $H_1=H_c$ can be used in case it is chosen not to determine d_f.

The pressure intensity q_t (Figure 2-5[b]) is used to calculate the critical interlock tension t_i.

$$t_i = \frac{q_t r}{C_l} \leq \frac{t_u}{FoS} \quad \text{(Eq. 11)}$$

where, q_t is pressure intensity (Figure 2-5[b]) in kPa or k/ft^2; C_l is constant (use 1 if q_t in kPa or use 12 if q_t in k/ft^2); t_u is ultimate interlock value (given in Table 3-1 and Table 3-2) in kN/m or k/in.; FoS values are given in Table 3-1 and Table 3-2.

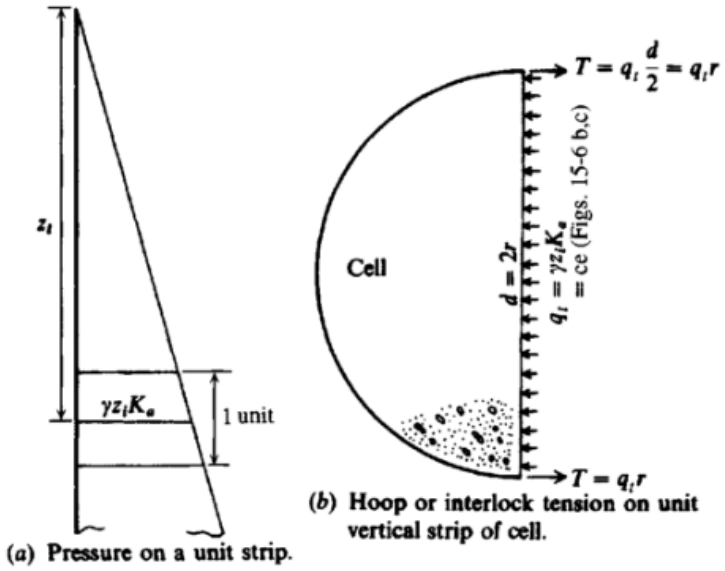

Figure 2-8 Calculation of cell interlock tension force. Using K` = Ka is suggested to calculate force Ps given in Figure 2-5(b)(Bowles, 1996)

Based on TVA (1966), the interlock tension of the connection pieces can be computed from the free body of the cell as given in Figure 2-9. The interlock tension in the connection is calculated using total force as follows:

$$T_{it} = \frac{q_t L}{\cos \alpha} \quad \text{(Eq. 12)}$$

where, L = 0.5 L` (Figure 2-9). The maximum interlock tension is depended on to use of a 30° Y or of a 90° T connection.

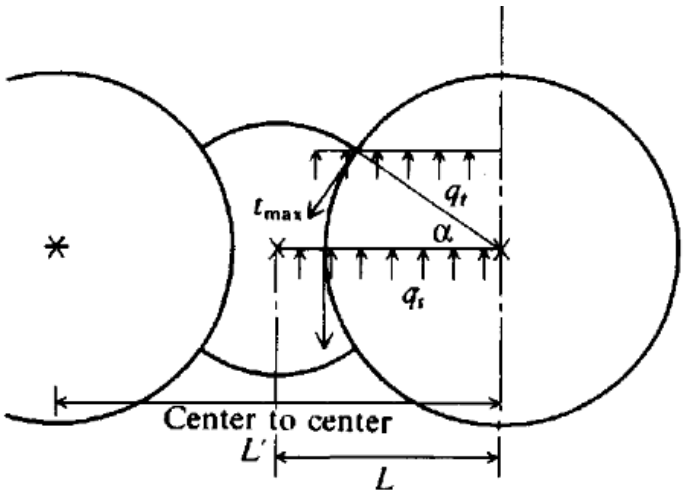

Figure 2-9 Y or T connection stresses based on TVA (Bowles, 1996)

2.7.4 Cell Shear Failure

To ensure stability against shear failure along the centerline of the cell, the combined shear resistance from the soil and interlocks must be at least equal to the shear caused by overturning. Assuming a linear pressure distribution across the cell's base, we can analyze this scenario. With the assumption of linear pressure distribution across the cell base (Figure 2-4[d]), the moment about the center of the cell:

$$M_o = \frac{2}{3} BV \quad \text{(Eq. 13)}$$

and V is driven from Eq. 13:

$$V = \frac{3}{2} M_o / B \quad \text{(Eq. 14)}$$

$$V_r = V_s + R_{il} \quad \text{(Eq. 15)}$$

$$V_s = P_s \tan \delta \quad \text{(Eq. 16)}$$

where, V_r is resisting shear; V_s is soil shear resistance; R_{il} is interlock resistance; P_s total shear force applied by soil.

For the stability, the total shear resistance force must be greater than total vertical shear force calculated by Eq. 14:

$$V_r \gg V \quad \text{(Eq. 17)}$$

There are different suggestions for the earth-pressure coefficient value, K' in the literature. While K' may be computed using the Mohr's circle construction, Maitland and Schroeder (1979), suggested using the K' value of 1, and Bowles suggested to use the value of 0.56.

2.7.5 External Bearing Capacity Failure

Bearing capacity (Figure 2-4[e]) recommended to be considered when cofferdams are based on soil. For the limit state calculations, first the cofferdam is converted to an equivalent rectangle (Figure 2-6). A unit width B (=1) and an initial L qual to the equivalent rectangle B are used for the calculations. The base eccentricity, e, is calculated using overturning failure considerations. Then, the effective foundation $L' = L - 2e$ is calculated. Then bearing capacity is calculated using Hansen bearing capacity equations with the effective base dimensions of $B \times L'$. this value is compared with the bearing capacity value under the toe half of the base (Bowles, 1996).

In the current study, bearing capacity was evaluated using Plaxis 2D, with empirically derived closed-form solutions serving as validation. Closed-form assessments followed traditional Terzaghi bearing capacity theory and generally matched well with outcomes from FE modeling, but it is noted that the ability of the FE models to capture eccentricity with greater accuracy likely led to slightly lower FoS from those simulations. Hence, the FoS from the Plaxis FE models are reported in the results sections for both Pier A (3.1) and Quay Wall (3.2).

3.0 RESULTS

3.1 PIER A

3.1.1 Stability

The FoS values obtained from stability analyses carried out in Plaxis 2D for Pier A are shown in the Table 3-1 below. These values are associated with the most onerous cross section determined through a preliminary taxonomic assessment. Based on the analyses carried out, the minimum embedment depth along the North side of Pier A must be at least 26.7 ft whereas along the South side it must be at least 24.5 ft.

Table 3-1
FoS values of internal and external failure modes obtained from current study and CH2M (1975) for Pier A.

Mode of Failure	FoS for Pier A				
	CH2M 1975 as-built	MM as-built [4]	Recommended FoS [1]	MM, as-built	Recommended FoS [1]
	Static			CLE[6]	
Internal – Tension [5]	1.70	1.73[3]	1.50	1.56	1.30
Internal - Shear	1.60	1.61	1.50	1.41	1.30
External – Bearing Capacity	3.20	3.30	3.00	2.14	1.50
External - Sliding	1.60	1.60[2]	1.50	1.39	1.10
External - Overturning	2.50	2.50[2]	3.00	2.18	1.30

[1] Based on Department of the Army U.S. Army Corps of Engineers, 1989. Engineering Manual 1110-2-2503

[2] Assumes water is only present on one side (true FoS would be much higher or indeterminate for symmetrical structure)

[3] Assumes that soil outside cell below dredge line is purely frictional (likely overconservative)

[4] Framework for revetment optimization and validation against as-built is given Section 2.5.

[5] Sheet pile interlock failure

[6] Contingency Level Earthquake

3.1.2 Revetment Geometry

Figure 3-1 below shows a comparison of back of wall pressures before and after adding the optimized revetment solution. The close match between the two curves for each side of Pier A validates the assumption that the addition of the revetment does not impact the computed factors of safety and can therefore be safely adopted.

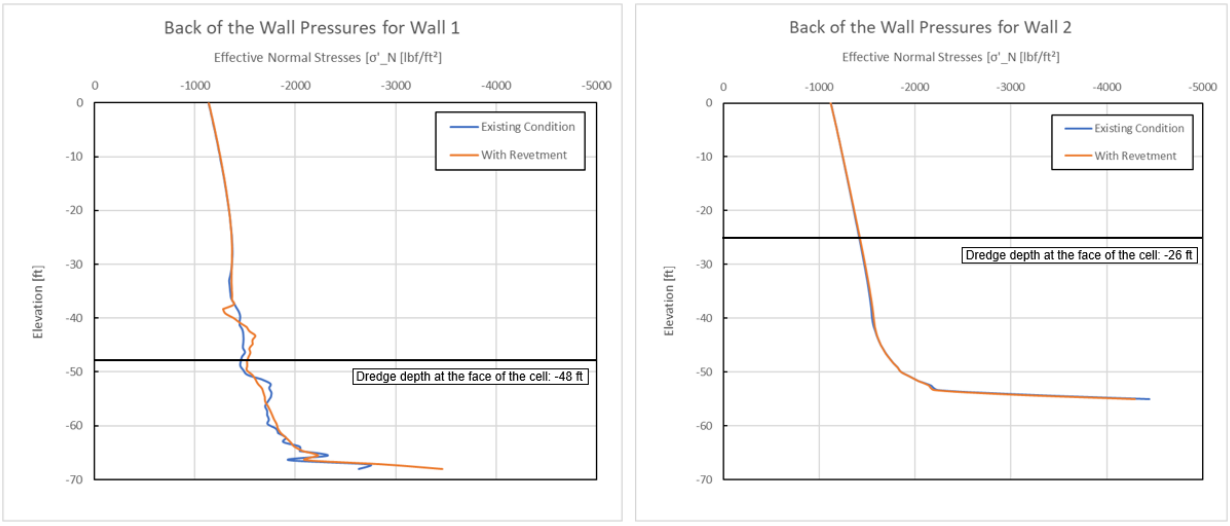

Figure 3 Stability Check for the back of the walls

3.2 QUAY WALL

3.2.1 Revetment Geometry

The optimized Quay Wall revetment geometry optimization in this study is based on the outcomes from the analyses carried out for Pier A. This approach is valid since the strategy for revetment optimization involved ensuring the stress state on the back of the wall remains unchanged from the existing condition. Hence, the geometry on the dry dock side of the Pier A cell is adopted for the Quay Wall.

3.2.2 Stability

The FoS values obtained from stability analyses carried out in Plaxis 2D for Quay Wall are shown in the Table 3-2 below. Based on the analyses carried out, the minimum embedment depth along the Quay Wall must be at least 26.7 ft.

Table 3-2
FoS values of internal and external failure modes obtained from current study and CH2M (1975) for Quay Wall

Mode of Failure	FoS for Quay Wall				
	CH2M 1975 as-built	MM as-built (2)	Recommended FoS (1)	MM as-built	Recommended FoS (1)
	static			CLE(4)	
Internal- Tension (3)	1.40	1.41	1.50	1.26	1.30
Internal - Shear	1.30	1.34	1.50	1. 17	1.30
External – Bearing Capacity	3.00	3.10	3.00	2.00	1.50
External - Sliding	1.40	1.50	1.50	1.21	1.10
External - Overturning	2.30	2.20	3.00	1.82	1.30

(1) Based on Department of the Army U.S. Army Corps of Engineers, 1989. Engineering Manual 1110-2-2503

(2) Assumes that soil outside cell below dredge line is purely frictional (likely overconservative)

(4) Contingency Level Earthquake

4.0 DISCUSSION

The stability analyses of Pier A and the Quay Wall presented in this report provide a comprehensive evaluation of both existing conditions and proposed remedial designs. The findings are grounded in historical context, modern geotechnical modeling, and rigorous FoS assessments, offering a robust framework for decision-making in the RD for the SIB Project Area.

4.1 HISTORICAL CONTEXT AND STRUCTURAL INTEGRITY

The historical failures of diaphragm cells at Pier A due to base sliding and piping underscore the importance of understanding past construction methods and material variability. The 1975 CH2M

Hill report highlighted issues such as poor compaction, welding defects, and corrosion, which contributed to structural failures. These insights informed the current analysis, particularly in identifying interlock tension as a critical failure mode.

4.2 ANALYTICAL APPROACH AND METHODOLOGY

The use of both traditional semi-empirical methods (e.g., Terzaghi's TVA method) and modern FEA via Plaxis 2D allowed for a nuanced understanding of failure mechanisms. The integration of CLE conditions and post-seismic liquefaction scenarios further enhanced the robustness of the analysis. Notably, the models demonstrated that both Pier A and the Quay Wall maintain acceptable stability under CLE demands, provided structural integrity is preserved.

4.3 KEY FINDINGS ON STABILITY

The FoS values for both structures generally exceed the minimum recommended thresholds, with bearing capacity consistently showing the highest safety margins. However, interlock tension and internal shear remain the most sensitive failure modes, particularly under seismic loading. The parametric sensitivity studies confirmed that even with conservative variations in soil properties, the structures remain within acceptable safety limits. While some modes fell below the recommended FoS for both Pier A and the Quay Wall, there are no instances for which instability (i.e., the FoS was less than 1.1) is expected under either static or CLE demands. Furthermore, the remedial actions recommended herein do not impact the FoS of any failure mode considered.

4.4 REVETMENT OPTIMIZATION AND DREDGING FEASIBILITY

A significant contribution of this study is the optimization of revetment geometries to facilitate deeper dredging without compromising structural stability. The analysis confirmed that the proposed revetment designs do not adversely affect back-of-wall pressures, validating their implementation. This optimization is crucial for maximizing dry dock utility while maintaining safety.

4.5 IMPLICATIONS FOR DESIGN AND MAINTENANCE

The findings emphasize the importance of ongoing structural maintenance, particularly regarding weld integrity and corrosion control. The historical failures due to welding defects and corrosion-induced crack propagation highlight the need for rigorous inspection protocols. Additionally, the study supports the feasibility of limited dredging activities, provided slope protection measures such as riprap are implemented.

STRUCTURAL DESIGN TECHNICAL MEMORANDUM

This page was intentionally left blank.

STRUCTURAL DESIGN TECHNICAL MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
SWAN ISLAND BASIN PROJECT AREA, CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

This Structural Design Technical Memorandum (SDTM) presents a summary of the structural analyses and design[1] of marine structures in the Swan Island Basin (SIB) Project Area required to accommodate remedial actions (RA) that are part of the 90% Remedial Design (RD). The Pre-Final 90% RD is conducted for the SIB Project Area within the Portland Harbor Superfund Site (PHSS) in Portland, Multnomah County, Oregon. The HydroGeoLogic, Inc. (HGL) team performed the work on behalf of the SIB RD Group based on the requirements of the PHSS Record of Decision (ROD) (EPA, 2017) and the Administrative Settlement Agreement and Order on Consent (ASAOC) at the SIB Project Area (EPA, 2021a).

Information presented in this SDTM has been:

- Collected in accordance with the final Pre-Design Investigation (PDI) Work Plan – approved by the U.S. Environmental Protection Agency (EPA) in May 2022 (HGL, 2022)
- Presented in the PDI Evaluation Report (ER) – approved by the EPA in January 2024 (HGL, 2024a)
- Presented in the Basis of Design Report (BODR) – approved by the EPA in December 2024 (HGL, 2024b)

The SIB Project Area has extensive infrastructure that will be impacted by implementation of the RA. The RD evaluated structures to determine if any required removal, replacement, or mitigation measures to accommodate the RA. All structures within the SIB Project Area, except for the Port of Portland Berth 308, were determined to be functional based on the definitions set by previously published EPA documents related to the PHSS (see Section 3.0.)

Analyses supporting the design of the RA structural mitigation measures, where required, are summarized herein and described in Attachments A, B, and C. The RD design for Project Area structures employs a performance-based specification design approach. Section 1.1 provides a detailed explanation of this design approach.

Section 1.0 provides overall general project information and outlines individual structures and elements of the RD. Section 2.0 describes the structural evaluation approach to be consistent with the overall PHSS design requirements. Section 3.0 defines functionality determination of each structure within the SIB Project Area and summarizes the functionality of each structure. Section

[1] This document is the 90% Design Submittal, but it is anticipated that additional detailed design will be carried out by the Remedial Action Contractor as part of the Remedial Action phase.

Corporate Headquarters
11107 Sunset Hills Road, Suite 400
Reston, Virginia 20190
703-478-5186

4.0 outlines the structural design criteria that apply to both existing and new structures. Section 5.0 summarizes key considerations for each structure.

1.0 GENERAL INFORMATION

This section provides an overview of general SIB Project Area information that informs the structural analyses completed as part of the RD. This section includes project data, provides a summary of existing structures, and gives an overview of the relevant elements of the remedial design.

1.1 DESIGN APPROACH

Two types of design approaches are typically used for RD as defined in the EPA's Remedial Design/Remedial Action Handbook (1995). Per Section 3.10.2 of the handbook:

> *Specifications, a generic term that includes drawings, are developed by the remedial designer and included in the RD package. Specifications contain a description of the technical requirements the constructor must meet to implement the RA and the criteria for determining whether these requirements are met. Two types of design specifications typically used in Superfund are detailed design and performance-based specifications.*

For this project, a performance-based specifications design approach was used by the RD team to develop design documents for every new or modified structure. The RD documents illustrate and specify the performance requirements for each structural design, and the RA Performing Parties or the RA Contractor (on behalf of the RA Performing Parties) will develop a final detailed design that meets the performance requirements shown in the RD documents.

The performance-based specifications design approach enables the creation of a cost-effective and detailed design by allowing the RA Contractor to determine how to meet the requirements set by the RD documents. This approach also enables the RA Contractor to implement innovative or proprietary construction methods and technologies.

1.2 PROJECT UNIT STANDARDS AND DATUM

Below is a summary of the units, vertical datum, elevations, and river levels referred to and utilized within the structural analysis across the SIB Project Area:

- Units: Imperial US units, unless noted otherwise
- Vertical Datum: North American Vertical Datum of 1988 (NAVD88)
- Elevations: All elevations reference NAVD88, unless noted otherwise
- River Levels: See Table 1-1

1.3 EXISTING STRUCTURES

Numerous different structures can be found throughout the SIB Project Area. Table 1-2 provides a summary of the existing structures. Impacts due to implementation of the RA were evaluated prior to commencement of the RD and are presented in the BODR (HGL, 2024b). Table 1-2

identifies key structural characteristics including structure type, age, estimated remaining design life, assessed condition, and under-structure slope profile.

It will be incumbent on the RA Performing Parties or the RA Contractor (on behalf of the RA Performing Parties) to complete Pre-Remedial Action (Baseline) Structural Condition Assessments of all existing structures prior to implementation of the RA to establish the condition of each structure at the time of construction. Baseline conditions will inform the RA Performing Parties' final detailed design and be compared to Post-Remedial Action (Final) Structural Conditions to identify damage caused during construction, if necessary.

1.4 REMEDIAL DESIGN OVERVIEW

For the structures, the RD considers RA work being done beneath and around structures. As presented in the Technology Application Decision Tree of the ROD (EPA, 2017), if a structure is functional and permanent then the RA may include the placement of a cap only or dredging and the placement of a cap.

The structural design uses geotechnical engineering information and requirements along with specific design criteria provided by the Remedial Design Guidelines and Considerations (RDGC) (EPA, 2021b) document. These design criteria include requirements for the structures and supporting soils for both static and seismic loading conditions. Both the design criteria provided by the RDGC and the geotechnical requirements were considered when the existing structures were evaluated, and the RA measures were determined. For detailed geotechnical information, refer to the Geotechnical Design Technical Memorandum (GDTM) (Volume I, Appendix I).

Slopes that support new caps, including those near or under structures, were assessed using geotechnical information and criteria that considered the cap construction and navigation needs. Where required to meet geotechnical requirements, existing slopes are shown to be regraded and/or stabilized to accommodate the RA. The impact on structures from slope changes near or under structures was assessed in accordance with The Structural Design Philosophy (Section 2.1) and Structural Design Criteria (Section 4.0).

For detailed information on cap design, dredging design, slope modifications, and geotechnical requirements, refer to the Cap Design Technical Memorandum (Volume I, Appendix E), Dredging Design Technical Memorandum (Volume I, Appendix H) and Geotechnical Design Technical Memorandum (Volume I, Appendix I).

1.5 SELECTED DREDGING AND CAP CONSTRUCTION

Refer to the Pre-Final 90% RD Drawings for sediment dredging and capping details included in the RD. Generally, the RD includes the dredging of sediment under and adjacent to structures and possible regrading of the existing slopes before placement of a cap.

2.0 STRUCTURAL EVALUATION APPROACH

This section details the evaluation method for structures in the SIB Project Area, focusing on achieving RAOs as specified in the ROD (EPA, 2017). Each structure poses distinct challenges and can be addressed by different methods, each affecting cost and complexity.

During the 50% RD Phase, conflicts between RDGC (EPA, 2021b) requirements and ROD Technology Application Decision Tree assignments were identified, particularly where capped slopes beneath structures failed to meet geotechnical criteria or where a stabilized slope supporting a cap was not compatible with protection of a structure's functionality. An SIB Project Area Design Philosophy and a Structural Action Decision Tree were developed to resolve these issues (reference Attachment A for more information).

2.1 STRUCTURAL DESIGN PHILOSOPHY

A design philosophy was developed in conjunction with the RD Project Coordinator to help guide the approach to structures within the SIB Project Area. Selection of structural design measures at each shoreline and overwater structure follows this design philosophy:

1. The RD should focus primarily on achievement of the RAOs.
2. The RD should be consistent with the ROD Technology Application Decision Tree (ROD Figure 28; EPA, 2017).
3. The RD should be consistent with EPA's RD guidance.
4. To achieve the RAOs, it is necessary to work near existing structures and on riverbank slopes, which may impact the existing structures. This impact needs to be mitigated for structures considered to be functional.
5. If, to achieve the RAOs, modification to or replacement of an existing structure is required, the RD team will seek a solution that balances construction cost and facility impacts and that is consistent with the applicable or relevant and appropriate requirements (ARARs) (EPA, 2017).

2.2 STRUCTURAL ACTION DECISION TREE

The treatment of existing structures is guided by the ROD. ROD Section 14.2.9.2 states, "Structures may be removed to access contaminated media unless it can be demonstrated that the structure is permanent (e.g., not floating or movable), functional (e.g., not beyond its design life and/or in disrepair), or needed for current or future property and waterway use." The use of the word "or" indicates that RA work needs to be done around existing structures if they are one of the following: permanent, functional, needed. Based on this, most structures within the SIB Project Area will remain and the remedial technology will be applied below and around structures. However, there may be a need to replace a permanent, functional, or needed structure if the presence of that structure prevents achievement of the RAOs. For example, if a structure is currently located on an over-steepened slope that requires regrading to achieve a stable cap, the structure may need to be removed or replaced.

In addition, the remedial design considers that the implementation of the RA must not compromise the structural integrity of any existing structure, and the effects of the RA on an existing structure must be mitigated if the RA negatively impacts a structure's integrity. The structure may need to be strengthened to accommodate the RA.

A structural action decision tree was adopted to evaluate each structure. This decision tree is shown in Figure 2-1 and summarized below:

1. Where the RAOs can be achieved with an existing structure in place, the structure is left in-place.
    a. Where the function or structural integrity of an existing structure is not adversely impacted, no further action is required. (Solution A/D)
    b. Where the function or structural integrity of an existing structure is adversely impacted by the RA, mitigation measures are needed to preserve the function and/or structure. (Solution B)
2. Where the presence of a structure prevents achievement of the RAOs, the structure is removed to enable the achievement of the RAOs.
    a. Where the structure is deemed **functional** (as defined in Section 3.0 below)**,** the structure is replaced with an equivalent structure following implementation of the RA. (Solution C)
    b. Where the structure is deemed **non-functional**, the structure is permanently removed. (Solution E)

3.0 FUNCTIONALITY DETERMINATION

The determination of functionality for existing structures is guided by both the RDGC (EPA, 2021b) and the ROD (EPA, 2017). These documents provide criteria for evaluating whether a structure is considered functional or non-functional in the context of remedial activities.

The RDGC document (EPA, 2021b) includes the language quoted here:

- Section 3.3 – Technology Assignment Application Flexibility
  Functional structures are defined as those structures that are currently in operation or are being used to stabilize the riverbank and expected to have a service life greater than 50 years. Nonfunctional or movable structures are expected to be removed or moved to allow access to contaminated material and implementation of the Technology Application Decision Tree as if no structure was present.
- Section 5.2.9 – Functional Structures Evaluation
  ROD Section 14.2.9.2. states, "Structures may be removed to access contaminated media unless it can be demonstrated that the structure is permanent (e.g., not floating or movable), functional (e.g., not beyond its design life and/or in disrepair) or needed for current or future property and waterway use." This determination shall be made by the [Performing Parties] for each structure within the remedy footprint, and the effects of such structures on the remedy implementability and effectiveness shall be evaluated. Any impacts to the permanent, functional, or

> *needed structures should also be considered during remedial design. Each shoreline and in-water structure shall be reviewed to determine if it is to be removed or not.*

The ROD (EPA, 2017) states in Section 14.2.9.2:

> *Structures may be removed to access contaminated media unless it can be demonstrated that the structure is permanent (e.g., not floating or movable), functional (e.g., not beyond its design life and/or in disrepair), or needed for current or future property and waterway use.*

Importantly, the terms "design life" and "service life" are distinct in engineering practice. As defined by the American Society of Civil Engineers *Manual of Practice (MOP) 130 – Waterfront Facilities Inspection and Assessment:*

- **Design life** refers to the theoretical life span estimated during the planning and design.
- **Service life** refers to the actual duration a structure performs its intended function, which may exceed the original design life through maintenance activities and repairs.

In evaluating functionality for RD, the following considerations were applied:

- Design life is a planning benchmark and does not reflect the actual operability or usefulness of a structure. Many structures continue to function well beyond their design life by implementing inspection routines, routine maintenance, and rehabilitation.
- Condition and use are both critical in assessing whether a structure is "in disrepair." A structure showing signs of deterioration may still be operable and fulfill a current need.
- Service life can be extended through regular inspection, maintenance, and repairs.

Therefore, the RD did not rely solely on design life, service life, or current condition to determine functionality. Instead, a structure was considered **functional** if it met the following criteria:

- **Permanent** (not floating or movable),
- **Operational** (currently used or capable of being used), and
- **Necessary** for current or anticipated future use.

Each structure was assessed prior to commencement of RD, in coordination with shoreline facility owners/operators, to determine their functionality. Information from this coordination is shown in Table 6-4, Section 6.2.1.2 of the BODR (HGL, 2024b.) During the Draft 50% RD phase, the functionality of each structure was reevaluated during shoreline facility owner/operator consultation workshops which resulted in the following additional information or changes to the functionality shown in the BODR:

- Berth 308: The designation in the "necessary" column was amended from "unknown" to "no." The structure is now considered non-functional.
- U.S. Navy Pier: The designation in the "necessary" column was discussed with the U.S. Navy. The U.S. Navy has classified the pier as in 'Layup' status meaning they are not

allocating funding for maintenance or upkeep of the pier. However, the U.S. Navy has not listed the pier for demolition. Therefore, the designation in the "necessary" column remains "unknown." Additionally, the RD has determined that this structure does not need to be removed to achieve RAOs. The structure is classified as functional.

- Lagoon Wharf (Berth 302 - 305): Although considered functional, the RD process has determined that RAOs cannot be achieved with the existing Lagoon Wharf structure in place. Geotechnical issues related to the riverbank (global and local slope stability, liquefaction, and lateral spreading) require a larger solution than modifying or shoring up the existing structure.
    - The global stability of the riverbank beneath the existing structure does not meet project design requirements, as the safety factor is well below the required level.
    - Similarly, the local stability of the ground beneath the existing structure falls short of project design requirements. Modifying the material beneath the structure—whether adding or removing and replacing—does not result in a stable slope that satisfies design requirements.
    - Additionally, the present riverbank configuration fails to meet seismic design standards, and both soil liquefaction and movement towards the water are likely during an earthquake. The existing structure lacks sufficient capacity to withstand these forces.

  To mitigate the geotechnical issues while implementing the remedy, the area will require ground improvements and new structures that can stabilize this area. Upon determining that the Lagoon Wharf needed to be removed and replaced, the facility operator (Vigor) hired their own engineering firm (KPFF) to review the RD team's findings. This firm's role was expanded to create a cost-effective wharf design that minimizes short- and long-term effects on operations due to implementing the remedy, which requires removing and replacing the existing structure. More detailed information regarding the RD team's approach and evaluation of alternatives is provided in Attachment C.

For each structure, a determination was made related as to whether a structure is permanent, operational, or necessary. Depending on the answers, each structure was given a functionality classification. These considerations and the results of the classification are shown in Table 3-1.

4.0 SHORELINE AND OVERWATER STRUCTURES DESIGN CRITERIA

The Shoreline and Overwater Structures Design Criteria is presented in Attachment A and includes the design criteria for assessment of existing structures, the criteria for design of new structures, and the material and durability requirements of the Pre-Final 90% RD components. This attachment includes the standards referenced, general design principles, the design criteria for soil structure analysis, and design to be implemented during the RA.

Additionally, the design criteria used to analyze and design new structures (functionally equivalent structures) in the SIB Project Area have been outlined in Attachment A. The new structures within the SIB Project Area presented herein include toe walls, mid-slope pinning walls to stabilize steep

slopes, and replacement of functional structures including pier structures and mooring infrastructure. The design life of new structures and their components have been specified, noting the desired service life and means of achieving the desired service life (reference Attachment A for additional information).

5.0 SUMMARY OF STRUCTURAL ASSESSMENTS AND STRUCTURAL DESIGN MEASURES TO ACCOMMODATE REMEDIAL ACTION

Each structure within the SIB Project Area has been assessed against the RD requirements for dredging, capping, and geotechnical slope stability under both static and seismic conditions. Where needed, measures have been designed to maintain functionality and mitigate against the risk of damage to or changed conditions for the structure. In some cases, to achieve the RAOs, toe walls or other slope stabilizing structures have been designed. In cases where slope stabilization methods are not sufficient, the complete removal/replacement of structures has been specified. For existing structures, the design was developed so that existing structures and elements of structures do not experience loads greater than those applied before the RA measures were implemented.

A detailed summary of the design considerations and design outcomes for all structures within the SIB Project Area is provided in Attachments B and C.

Table 1-1
River Levels
Structural Design Technical Memorandum, Swan Island Basin Project Area, Portland Oregon

River Level	Elevation (feet NAVD88[1])
Ordinary High Water (OHW)	+20.08
Mean High Water (MHW)	+13.00
Ordinary Low Water (OLW)[2]	+7.30
Columbia River Datum (CRD)	-5.28

Notes:
[1] NAVD88 = North American Vertical Datum of 1988
[2] The Mean Low Water elevation of +7.30 feet NAVD88, as measured at the U.S. Geological Survey 14211720, Morrison Street Bridge gage, is used as an approximation of OLW for Swan Island Basin.

Table 1-2
Existing Structures Summary
Structural Design Technical Memorandum, Swan Island Basin Project Area, Portland Oregon

Structure	Structure Type	Age	Estimated Remaining Design Life (years)[1]	Assessed Condition	Under-Structure Slope Profile
U.S. Coast Guard Pier	Timber pier	50	30-40	Fair	Flat to 2H:1V
U.S. Coast Guard Dock	Floating Dock	50	30-40	Fair	Flat to 2H:1V
U.S. Navy Pier	Timber pier/wharf	51	30-40	Fair	1.25H:1V to 6H:1V
Marine Consortium Pier	Timber pier/wharf	Unk	30-40	Fair	1H:1V to 4H:1V
Dredge Base	Timber pier	54	0-10	Serious	1.5H:1V to 11.5H:1V
Berth 311	Timber wharf	58	0-10	Serious	2.5H:1V to near flat
Swan Island Boat Ramp	Boat Ramp	37	30-40	Fair	3.5H:1V to 8H:1V
Wind Tunnel	Steel piled sub-structure	22	45-50	Satisfactory	0.75H:1V to 3.5H:1V
Berth 308	Timber pier	53	15-25	Poor	1.5H:1V
Berth 307	Timber pier	53	15-25	Poor	1H:1V to 1.5H:1V
Berth 306	Timber pier	53	30-40	Fair	1H:1V to 7H:1V
Lagoon Wharf (Berths 302 – 305)	Timber marginal wharf	74	15-25	Poor	0.5H:1V to 3H:1V 0.9H:1V to 3H:1V 0.5H:1V to 4.5H:1V 0.7H:1V to 3H:1V
Pier A	Cofferdam pier	62	0-10	Serious	3.5H:1V
Pier C	Piled steel/reinforced concrete pier	62	30-40	Fair	5H:1V to nearly flat
Quay Wall	Cofferdam Quay Wall	62	0-10	Serious	2H:1V to 4.5H:1V 2H:1V to 16H:1V
SCC Floating Dock	Floats with piles	Unk	35-50	Satisfactory	3.5H:1V to 10H:1V 4H:1V to 15.5H:1V
East Pier	Tabletop pier with gangways	45	30-40	Fair	1.5H:1V to 10H:1V
West Pier	Steel/RC piled pier	45	15-25	Poor	1.5H:1V to 10H:1V
Demo Pier	Steel/RC piled pier	38	30-40	Fair	1.5H:1V to 7.5H:1V
Pier D	Steel/RC piled pier	45	>50	Fair	Flat

Notes:
[1] Estimated remaining design life established at the time of Basis of Design Report (HGL, 2024b) preparation based on available data and observable structural elements, and assumes ongoing inspection, maintenance and repair/replacement of structural elements is performed on a routine basis.

ATTACHMENT A
SHORELINE AND OVERWATER STRUCTURES
STRUCTURAL DESIGN CRITERIA

This page was intentionally left blank.

1.0 INTRODUCTION

This document outlines the structural design criteria employed to assess potential effects on the overwater structures within the SIB Project Area resulting from Remedial Action (RA) activities. It details specific evaluation standards for each structure that supplement the Structural Design Philosophy defined in Section 2.1 of the Structural Design Technical Memorandum and supports the selection of appropriate structural solutions to advance RAs and achieve Remedial Action Objectives (RAOs).

The organization of this attachment aligns with the Structural Action Decision Tree described in Section 2.2 and illustrated in Figure 2-1 of the Structural Design Technical Memorandum. This document lists pertinent federal, state, local, and private standards and requirements that must be followed throughout the structural design process. Additionally, this document includes adopted decisions regarding design requirements and interpretations of design standards.

2.0 DETAILED EVALUATION MATRIX

A comprehensive evaluation matrix was implemented to analyze each structure within the SIB Project Area, utilizing the Structural Action Decision Tree to identify the appropriate solution. The following points summarize the approach as shown in Figure A-1:

1. Evaluate existing or as-built slope stability for the static and Contingency Level Earthquake (CLE) conditions.
2. Assess remediated slope stability (existing slope incorporating chemical isolation cap) for the static and CLE conditions. Determine *Initial Conforming Slope* geometry and composition that meets Design Criteria for Slope Stability and RAOs.
3. Compare the *Initial Conforming Slope* to the as-built ground conditions around piles or the existing conditions around piles where as-built information is not available.
    a. Where the *Initial Conforming Slope* is similar to the as-built/existing condition and the impacts on structural performance are determined to be negligible, adopt **Solution A/D**.
        i. **Solution A** applies where the structure is functional and the RAOs can be achieved/constructed with the structure left in place
        ii. **Solution D** applies where the structure is not functional and the RAOs can be achieved/constructed with the structure left in place
    b. Where the *Initial Conforming Slope* differs significantly from the as-built or existing condition and where the impacts of achieving the RAOs could be detrimental to a structure and/or implementation of the RAOs are not achievable with the structure left in place, then:
        i. If the structure is not functional, adopt **Solution E**.
        ii. If the structure is functional, perform structural analysis to determine the impacts on the structure's performance when subjected to static and CLE demands, then:

1. If the impacts are not considered significant to the structure's performance, adopt **Solution A**.
2. If the impacts are detrimental to the structural performance, evaluate options to strengthen the existing slope and maintain as-built slope angles. Options to evaluate include retaining walls, mid-slope pinning walls, or the use of toe walls.
3. High-level material cost estimates of slope strengthening over the length of impacted shoreline are compared against estimates of structural replacement and flattening of the slope.
    a. Where slope strengthening is considered more efficient, adopt **Solution B**.
    b. Where the *Initial Conforming Slope* is considered incompatible with the existing structure or where structural replacement and slope flattening is considered more efficient, adopt **Solution C**.

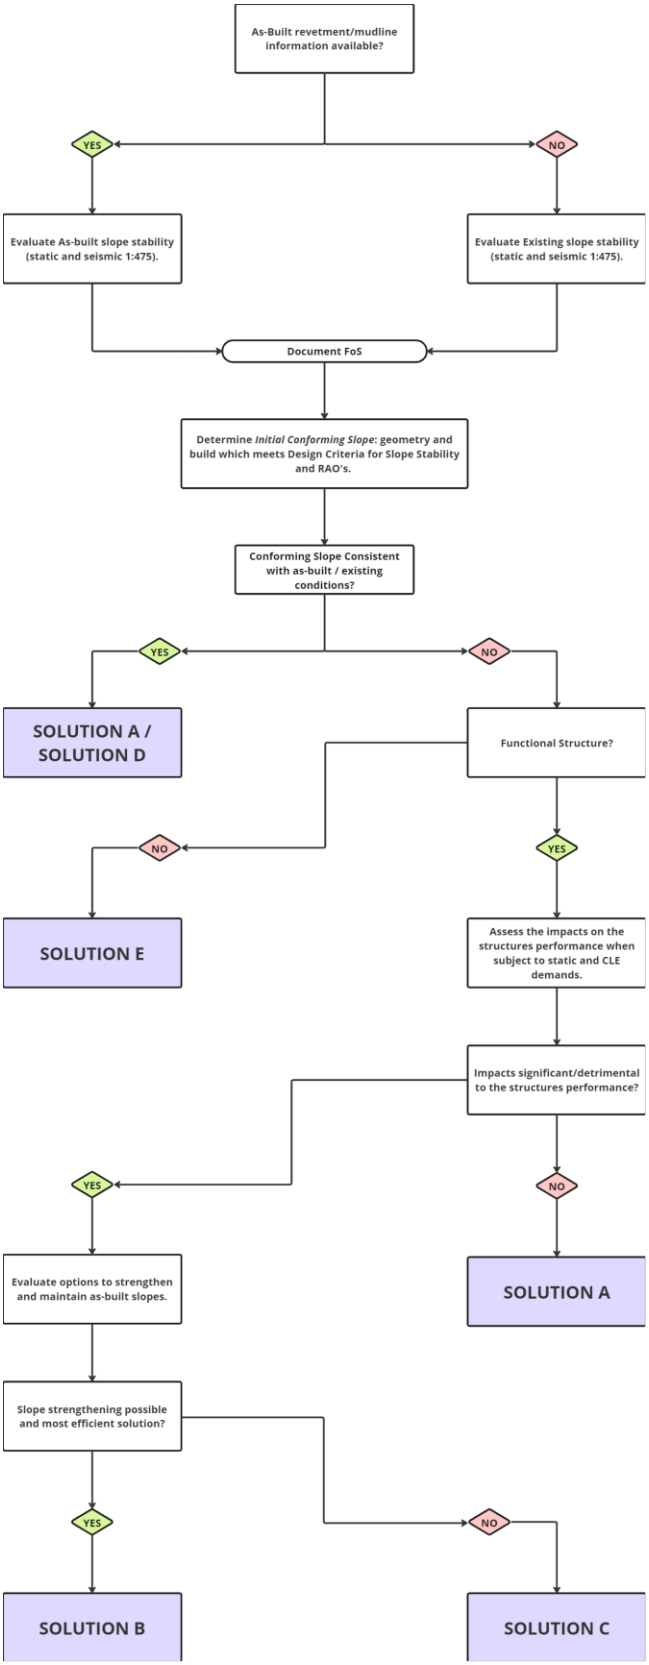

Figure A-1 – Detailed Evaluation Matrix

3.0 STANDARDS OF REFERENCE

Table A-1 lists standards referenced for the analysis and design of new structures and structural elements for the RD. This table also identifies design criteria for which the standard relies upon. All standards of reference listed are to be the latest editions released for industry use unless noted otherwise.

Table A-1: Standards of Reference

Standard	Requirement specified
Oregon Structural Specialty Code (OSSC) 2022	General Principles applied to existing and new structures
International Building Code (IBC) 2021	General Principles applied to existing and new structures
International Existing Building Code (IEBC) 2021	General Principles applied to existing structures
City of Portland Title Codes: Title 24 Building Regulations – Chapter 24.85 Seismic Design Requirements for Existing Buildings Title 28 Floating Structures	General Principles applied to existing structures
Port of Long Beach (POLB) Wharf Design Criteria, May 20, 2015 (POLB, 2015)	General design requirements and loading standard specific for new wharf structures
Unified Facilities Criteria (UFC) Piers and Wharves (UFC 4-152-01), August 2024.	General design requirements and loading standard specific for new wharf structures
California Building Code (CBC) (2022) "Chapter 31F [For SLC], Marine Oil Terminals," January 2023 (MOTEMS, 2022).	General design requirements and loading standard specific for new and existing terminal structures. Design of mooring forces/systems for new structures
AASHTO LRFD Bridge Design Specifications 10th Edition, 2024 (AASHTO, 2024).	Design life of new structures, components and durability requirements.
American Society of Civil Engineers (ASCE) 7-22 Minimum Design Loads for Buildings and Other Structures 2022	National Loading Standard, conformance with achieves Building Code Compliance
ASCE 41 2017 – Seismic Evaluation and Retrofit of Existing Buildings	Evaluation of seismic performance of existing structures to remain
ASCE 61-14 – Seismic Design of Piers and Wharves	Analysis and design of new structures for seismic effects
PIANC Guidelines for the Design, Manufacturing and Testing of Fender Systems, 2024 (PIANC, 2024).	Analysis and design of berthing and mooring systems for new wharf structures
ACI 318 – Building Code Requirements for Structural Concrete	Standard for design of structural concrete

4.0 STRUCTURES DEMOLISHED TO ACCOMODATE THE REMEDIAL DESIGN (SOLUTION C AND E)

In accordance with Figure A-1, where slope stability criteria cannot be achieved and where the existing structure is not compatible with a stable slope the structure is removed to accommodate the RA. Where a structure is functional, an equivalent structure is reconstructed following implementation of the RA. Where structures are not considered functional the structures are removed permanently.

Shoreline facility owner/operator consultation was conducted during the 50% RD phase in which the functionality of structures was confirmed. Structures that are required for current or future use or which have not been officially removed from service were classified as functional.

5.0 EXISTING STRUCTURES PROTECTED IN PLACE (SOLUTIONS A, B, AND D)

The following outlines the overarching design principles and criteria applied in evaluating each existing structure within the SIB Project Area. This assessment also includes the slopes located beneath and adjacent to these structures, which are preserved in their current state under Solutions A and B.

5.1 GENERAL PRINCIPLES

The following general principles were derived as a basis of analysis for existing structures within the SIB Project Area which are designated as protected in-place.

1. Following implementation of the RA, slopes subject to RA will have geotechnical factors of safety (FoS) greater than or equal to those before RA.
2. Following implementation of the RA, any modifications to structures required to meet changed conditions due to the RA will comply with the relevant codes (i.e., current) and standards of reference. However, where a structure is isolated from the impact of implementation of the RA through means of toe walls or pile isolation measures, existing structures will be deemed to have “code compliance not impacted” and assumed to be in compliance with the relevant codes at the time of their construction.
3. It is assumed that all structures and structural elements are in a serviceable condition.
4. As-built ground profiles are based on existing as-built structural drawings and are assumed to represent actual as-built structural and geotechnical configurations. It is assumed that structures will perform as originally intended when ground conditions are returned to profiles shown on the as-built drawings.

5.2 DESIGN CRITERIA – STRUCTURES AND SLOPES SUPPORTING STRUCTURES

The following design criteria were used to assess existing structures and slopes beneath structures in accordance with the Detailed Evaluation Matrix (Figure A-1). Table A-2 summarises the development of solutions based on the initial conforming slope and the impacts on the structure.

Table A-2 Development of Structural Solutions

Design Criteria Achieved?		Solution	
Slope Stability (Section 5.2.1)	**Impacts on Structure (Section 5.2.2)**	**Type**	**Mitigations**
Yes	No	Solution A	Not applicable
Yes	Yes	Solution B	Structural modification
No	Yes	Solution B	Ground improvements

5.2.1 Slope Stability

The following design criteria applies to under-structure and structure adjacent slopes, ground improvements required to stabilize slopes, and toe walls or retaining walls:

1. FoS Performance Requirements:
    a. Minimum static FoS: 1.5
    b. Minimum CLE FoS (under structures): 1.1
2. Comparative Performance Requirements:
    a. The calculated static FoS following RA shall be greater than or equal to the calculated static FoS for the existing condition and the as-built condition before RA.
    b. The calculated seismic CLE FoS following RA shall be greater than or equal to the seismic CLE FoS for the existing condition and the as-built condition before RA.

5.2.2 Structural Impact

The following design criteria apply to structures that are impacted by the RA. Following implementation of the RA, protected in-place structures will meet the requirements of City of Portland Building Code Title 24. This is achieved by demonstrating:

1. The demand to capacity (D/C) ratio for any structural element of an existing structure following RA shall be within 10% of the D/C predicted for the existing or as-built before RA. This is achieved by:
    a. Subjecting structures to earth pressures (static and seismic) no greater than before RA,
    b. Providing structures with geotechnical resistances following RA which achieves D/C criteria (above), and
    c. Not subjecting structures to detrimental loads such as down drag on piles or additional horizontal soil loads.

5.3 TEMPORARY CONDITION (DURING REMEDIATION)

The RA Contractor's chosen means and methods for construction have the potential to cause temporary conditions that result in impacts to structures. As means and methods are incumbent on the RA Contractor to determine, impacts from temporary conditions have not been contemplated as part of the RD. The RA Contractor is responsible for any temporary conditions and must execute their work without destabilizing structures during remediation activities.

6.0 DEMOLITION AND FUNCTIONAL-EQUIVALENT REPLACEMENT (SOLUTION C)

In accordance with Figure A-1, where slope stability criteria cannot be achieved and the existing structure is not compatible with a stable slope, the structure is removed to accommodate the RA and a functionally equivalent structure is constructed. All new structures are designed in accordance with Section 7.0.

7.0 DESIGN CRITERIA – NEW STRUCTURES

The following describes the design criteria used to analyse and design new structures in the SIB Project Area including design loads and material parameters for structural components. New structures within the SIB Project Area include:

- Functional-equivalent replacement structures (Solution C),
- Ground improvement structures (Solution B) including toe walls or mid-slope pinning walls to support stable slopes, and
- Structural mitigations (Solution B) to address detrimental impacts on structures protected in-place.

7.1 UTILITIES, FURNITURE, APPURTENANCES

7.1.1 Safety Ladders

Safety ladders are provided on replacement, accessible overwater structures in accordance with UFC 2024. Ladders are located at 100-foot centers maximum, to a depth of +2.10 feet.

7.1.2 Bull rails

Bull rails are provided on the edges of replacement, accessible, overwater structures for the protection of mooring lines.

7.1.3 Gangways

New gangways are provided for access to new structures where existing gangways are unable to be re-utilized.

7.2 DESIGN LOADS

7.2.1 Structure Risk Category

Structure risk categories used to determine environmental loads (flood, snow, ice, and earthquake) were established in accordance with ASCE 7-22, clause 1.5 as follows:

- Berth 306 and 307 pier structures: II
- Berth 306 and 307 accessible dolphins: II
- All other structures: I

7.2.2 Seismic Performance Requirements

7.2.2.1 Design Classification

Design classifications were established in accordance with ASCE 61-14, clause 2.2. Classifications were assigned as one of the following:

- High: "Essential to the region's economy or post-event recovery"
- Moderate: "Secondary importance to the regional economy, not essential to post-event recovery, however, require performance greater beyond life safety"
- Low: "Not assigned a "High" or "Moderate" classification.

All structures are considered Design Classification **Low**.

7.2.2.2 Performance Levels

The following Performance Levels were applied in accordance with ASCE 61-14, clause 2.4:

- All structures: Life Safety Protection

ASCE 61-14 defines performance meeting the requirements for Life Safety Protection as:

- The post-earthquake damage state is such that the structure continues to support gravity loads,
- Damage that does occur does not prevent egress, and
- There is no loss of containment of materials in a manner that would pose a public hazard

7.2.3 Seismic Analysis/Design

Seismic analysis and design of new structures were in accordance with ASCE 61-14 incorporating the following:

- Where necessary, kinematic loads on piles (Clause [cl.] 4.5.5)
- Displacement-based design using a 2-D or 3-D non-linear static pushover (cl. 6.7.2)
- Steel pipe piles and concrete pile plugs are allowed to yield. All other elements are capacity protected (6.9)

- Design and detailing to meet the requirements of cl. 7

7.2.4 Seismic Response Spectrum

A site-specific seismic response spectrum was determined for the SIB Project Area and is defined in the GDTM.

7.2.5 Dead Loads

The dead loads of structures included the weight of all construction materials and permanent fixtures/furniture. Dead Loads were derived in accordance with construction material densities and their geometries. Material densities were in accordance with UFC 4-152-01, clause 3-2.2 as follows:

- Reinforced/precast concrete 160 pounds per cubic foot (lb/ft3)
- Steel 490 lb/ft3
- Asphalt paving 140 lb/ft3
- Engineered backfill (compacted) 150 lb/ft3
- Rock/riprap 125 lb/ft3

7.2.6 Superimposed Dead Loads

The following superimposed dead load (SDL) were applied over the plan area of new structures to account for services, fixtures and furniture:

- Berth 306 and 307 piers: 5.5 pounds per square foot (psf)

7.2.7 Shrinkage Loads

Shrinkage strains were considered in accordance with The Precast/Prestressed Concrete Institute (PCI) Design Handbook cl. 4.11.13 as reference in UFC 2024. The following applies:

- Final shrinkage strain: 560x10-6 inch/inch
- Correction for relative humidity (RH) of 80%: 0.86
- Correction for Volume to Surface Ratio (V/S ~14-16): 0.54
- Final corrected shrinkage strain: 260x10-6 inch/inch

7.2.8 Creep

Creep loads were assessed to be non-critical since prestressed and post-tensioned concrete are not utilized in the project.

7.2.9 Thermal Loads:

Thermal expansion and contraction strains were assessed in accordance with AASHTO 2024 cl. 3.12.2.2 for the Portland Harbor location as follows:

- Design minimum temperature (Figure 3.12.2.2-2): 10ºF (-12ºC)

- Design maximum temperature (Figure 3.12.2.2-1): 110ºF (43ºC)
- Construction temperature: 59ºF (15ºC)

7.2.10 Live Loads

Live load considerations for the structural design of new structures are detailed below.

7.2.10.1 Berth 306/307 Piers:

In lieu of more detailed information from the property owner/operator, Live Loads were in accordance with UFC 4-152-01, cl. 3-3 for **Berthing (all others)** classification.

7.2.10.1.1 Uniformly Distributed Load

The existing berth capacity, based on a 1989 assessment, is as follows:

- 225 psf uniformly distributed load (UDL), although original intent may have been 600 psf
- 12 kips concentrated load

Adopted Design Loads

- 600 psf applied over any/all areas to produce the most adverse effect.
- UDL was placed directly surrounding point load plant, however not in combination over the same area.
- Impact factors were not applied with UDL

7.2.10.1.2 Road-going vehicular loading

- *Design Truck* and *Design Tandem* to AASHTO LRFD (Refer UFC 4-152-01 Figure 3-1)
- Impact Factor of 1.15 applied to superstructure elements

7.2.10.1.3 Rail-Mounted Quay Crane

Not applicable for Berth 306/307 piers.

7.2.10.1.4 Mobile Crane

- 90-ton capacity mobile crane (Refer UFC 4-152-01 Figure 3-4)
- Outrigger Float Loads:
    - 160,000 lbs per float (boom over corner)
    - 144,000 lbs per float (boom over back or side)
    - Minimum float area 400 square inches (in^2)
- Impact Factor of 1.15 applied to superstructure elements

7.2.10.1.5 Fork Hoist

- 20-Ton fork hoist. Refer UFC 4-152-01 Figure 3-4
- Max Wheel Loads:
    - Each Rear Single Tire: 2,500 lbs
    - Each Front Dual Tire: 49,000 lbs
- Impact Factor of 1.15 applied to superstructure elements

7.2.10.2 Berth 306/307 Dolphins, POP Dredge Base Dolphins:

7.2.10.2.1 Uniformly Distributed Load

- 105 psf applied over any/all areas to produce the most adverse effect.
- Impact factors were not applied with UDL.

7.2.11 Berthing Loads

Berthing and mooring loads relating to the structural design of new structures are detailed below.

In lieu of more detailed information from shoreline facility owners/operators, vessel characteristics were evaluated based on vessels which are known to have berthed at the existing structures.

7.2.11.1 General

7.2.11.1.1 Berthing Impact Load

Berthing impact loads were determined in accordance with PIANC, 2024, using berthing energies evaluated from site specific vessel characteristics for each structure (detailed below).

7.2.11.1.2 Heave and Surge Loads

Heave (vertical component of force) and surge (longitudinal component of force) actions acting on fendering systems were calculated as the product of the berthing impact loads and the coefficient of friction assumed between the ship's hull and fendering system using the following friction coefficients (UFC 4-152-01):

- Steel Hull to timber fendering: 0.60
- Steel Hull to steel fendering: 0.25
- Steel Hull to Ultra-High Molecular Weight (UHMW) fendering: 0.20
- Steel Hull to Rubber fendering: 0.70

7.2.11.2 Berths 306 and 307 Dolphins, POP Dredge Base Mooring Piles, Berth 311 Dolphin:

The following design vessel information was considered to apply:

Table A-3 Design Vessel Information

Structure	Berth 306 & 307	Berth 311
Vessel Characteristic	**Design Vessel**	**Design Vessel**
Design Vessel	Suezmax Oil Tanker	400-ft LOA Barge
Length Overall (LOA)	958 feet (ft)	400 ft
Maximum Displacement	144,461 Tons (T)	29,366 T
Beam, B	179 ft	100 ft
Max Draft	35 feet (at ordinary high water, depth-limited)	24 feet
Length between perpendiculars (LBP)	912 feet	400 feet
Allowable Hull Pressure	46.4 pounds per square inch (psi) (PIANC 2024, Table 6-6)	29 psi (PIANC 2024, Table 6-6)
Friction Coefficient	PIANC 2024, Table 8-2	PIANC 2024, Table 8-2
Approach Velocity Normal to Fender Line, v	0.18 feet per second (ft/s)	0.33 ft/s
Hull Fender Contact Point Distance From Bow Perpendicular to Point of Initial Impact	¼ Point	¼ Point
Maximum Approach angle, α	6º (PIANC, 2024, Table 5-5)	6º (PIANC, 2024, Table 5-5)
Partial Energy Factor	1.15	1.15

7.2.11.2.1 Berthing Energy and Fender Reactions

The berthing energy demand induced by the design vessel and to be absorbed by the proposed fender was calculated using the methodology outlined in PIANC (2024). The berthing analysis considered several factors, including vessel displacement, berthing velocity, vessel approach angle, eccentricity coefficient, virtual mass factor and partial energy factor. The analysis included the following assumptions.

- The dock was prescribed in the analysis as a continuous wharf with partially closed support structures that allow water to flow underneath.
- Berthing of the design vessel was assumed to be in "favorable" conditions as defined in PIANC (2024).
- Quarter-point berthing configuration was assumed, considering the first point of contact on the vessel during berthing will be at a distance of one quarter of the Length Overall (LOA) from the bow of the vessel.

Berths 306 and 307 Dolphins:

The berthing analysis results indicated that the existing fenders should be replaced with new Trelleborg Cell Fender SCK 1150 E1.4 (or equivalent). The computed FoS in the energy absorption capacity was above 1.0 under the assumptions listed above. Under the favorable environmental conditions during vessel operations, pilots can exercise a high level of control for large vessels; during the berthing process they tend to impinge on the fenders very slowly, and parallel to the berth such that more than one fender absorbs the berthing energy. In addition, the

anticipated berthing frequency will be relatively low. Therefore, the calculated factor of safety in energy absorption capacity for the selected fender is conservative. Final design energies and reactions applied to structures are summarized below:

- Kinetic energy absorbed by fendering system: 176 kip-ft
- Design fender reaction: 187 kips

7.2.12 Mooring Loads

Berths 306 and 307 Dolphins:

Static mooring analysis was conducted at Berths 306 and 307 using the mooring analysis software OPTIMOOR (TensionTech, 2024) to evaluate maximum bollard and fender loads under 100-year return period wind conditions. Historical aerial imagery was reviewed to identify the largest vessel historically moored at the berth(s) revealing ships up to 958 ft (292 meters) in length and 179 ft (54.5 meters) in beam—dimensions consistent with a Suezmax-class crude oil tanker.

Based on these findings, the Suezmax tanker *DONAT* was selected as the representative design vessel. The vessel model was scaled to the observed maximum dimensions (length overall: 292 m; beam: 54.5 m). Windage areas (side-on and end-on) were estimated by delineating scaled polygons using the vessel's CAD design drawings. The vessel mooring configuration was analyzed in OPTIMOOR using a standard mooring layout portside with a maximum of two lines per bollard. Bollard and fender locations were based on proposed site configurations. Due to the vessel's size, it was positioned between Berths 306 and 307, which is consistent with historical mooring patterns in the aerials. In lieu of more detailed analysis, mooring points are provided along the berthing line of each structure to match the existing berth configuration.

Simulations were run for wind loads from all directions at ordinary high water (OHW) and included wind shielding effects from surrounding topography. Analysis results indicate that bollards and fenders are subject to maximum loads of approximately 75 metric tons (MT) and 76 MT, respectively, under these conditions.

- Off-berth mooring load: 75 MT (168 kips)
- Design fender reaction: 76 MT (170 kips)
- One 75 MT safe working load (SWL) double bitt bollard will be provided on each structure. For the design of each structure, each bollard will be loaded to its SWL.

Dredge Base Mooring Piles:

- Off-berth mooring load: 14 MT (31 kips)
- On-berth mooring load: 15 MT (32 kips)

Berth 311 Dolphin:

- Off-berth mooring load: 14 MT (31 kips)

- On-berth mooring load: 15 MT (32 kips)

7.2.12.1 Mooring Load Application:

Design for mooring considers application of mooring loads as follows:

- Case 1: Horizontal load, perpendicular to the berth
- Case 2: at 45º to horizontal, perpendicular to the berth
- Case 3: Horizontal load, at 45º to berth

7.2.13 Current Loads

Current loads were evaluated in accordance with the project Metocean analysis. Modeled hydrodynamics per the Remedial Design Work Plan (RDWP) (HGL, 2025) demonstrates relatively quiescent conditions in the vicinity of all berths, resulting in current-induced forces that are negligible relative to other design loads acting on the vessel. Therefore, current loads were neglected in the mooring analysis.

7.2.14 Wind Loads

Wind loads were calculated in accordance with OCIMF (2019) guidelines and adjusted for 30-second gust conditions. The analysis utilized 100-year return period wind data from the Remedial Investigation/Feasibility Study (RI/FS) (EPA, 2016) for wind load calculations.

7.2.15 Wave Loads

Wave loads were evaluated in accordance with the project Metocean analysis. Wind wave modeling described in the RDWP (HGL, 2025) indicated relatively minimal wave activity in the berth vicinity, resulting in wave-induced forces that are negligible compared to other design loads acting on the design vessel. Therefore, wave loads were neglected in the mooring analysis.

7.2.16 Buoyancy Loads

Buoyancy loads were not determined to be critical for any of the new structures.

7.3 LOAD COMBINATIONS

Loads were combined in accordance with the following reference standards and clauses:

- SLS Static Loads for evaluation of stress and crack control: AASHTO, 2024 cl. 3.4.1 (Service I)
- ULS Static Loads for evaluation of strength: POLB, 2015 Table 3-4
- Seismic Loads: ASCE 61-14 cl. 3.6

8.0 MATERIALS AND DURABILITY

This section describes the minimum construction material requirements from which new structures in the SIB Project Area are designed, the required service life, and means of achieving the required service life.

8.1 DESIGN LIFE

All new structures and structural elements will have a design life of 75-years in accordance with AASHTO 2024, unless reduced by the shoreline facility owner/operator having jurisdiction.

The durability design life of structural components will be as follows:

- Reinforced concrete: 75-years
- Steel pipe piles: 75-years
- Steel sheet piles: 75-years
- Structural steel: 75-years*
- Timber: 25-years with provision for repair/replacement
- Miscellaneous steel: 25-years with provision for repair/replacement
- Proprietary components: Per manufacturers specifications

*All structural steel shall be hot-dip galvanized in accordance with ASTM A123/A123M and will require maintenance to achieve the prescribed design life.

Requirements for materials used in the structural components are provided in Section 8.2.

8.2 STRUCTURAL MATERIALS

Minimum material requirements for new structures are outlined below.

8.2.1 Reinforced Concrete

All concrete shall meet the requirements of exposure class C1 to ACI 318 Table 4.3.1.

All concrete shall have a minimum compressive strength at 28-days as follows:

- Cast-in-place concrete: 5000 pounds per square inch (psi)
- Precast concrete: 5000 psi

Maximum water to cement (w/c) ratios vary by structure type, reference the specifications.

All reinforcing steel shall be deformed steel bars conforming to ASTM A615, Grade 60

All reinforcement cover will be 3.0” (75mm) minimum in accordance with Table 5.10.1-1 of AASHTO for a Coastal Environment

Reinforced concrete elements will be designed to meet crack control criteria to AASHTO, 2024 cl. 5.6.7 for the SERVICE I. SLS load combination outlined in section 7.3.

8.2.2 Steel Sheet Piles

Steel sheet piles shall conform to ASTM A690/A690M, or ASTM A572/A572M, Grade 50.

8.2.3 Steel Pipe Piles

Steel pipe piles shall conform to ASTM A252, Grade 3 or similar and shall have a minimum yield strength of 45 kilo pounds per square inch (ksi) (290 megapascals [MPa]) and a maximum yield strength of 52 ksi (360 MPa). Parent metal shall achieve a minimum elongation of 20% and a minimum Charpy V-Notch (CVN) energy of 27J at 32ºF (0ºC).

Corrosion of structural steel pipe piles and steel sheet piles shall be in accordance with ASCE MOP 130, Table 4-5 as follows:

- Common Fresh Water (River, Ship canal, etc.) for a 75-year design life.
- Steel pipe piles will be designed with a corrosion allowance of 1.15 mm from the internal and external faces (2.30 mm total).
- Steel sheet piles will be designed with a corrosion allowance of 1.15 mm from both faces (2.30 mm total).

8.2.4 Structural Steel

All structural steel shall have a minimum yield strength of 45 ksi (290 MPa) and a maximum yield strength of 52 ksi (360 MPa).

8.2.5 Miscellaneous Steel

- All miscellaneous steel shapes, plates, bolts, nuts, and washers shall be stainless steel unless otherwise noted;
- All stainless steel shall be type 316;
- All bolts and nuts not required to be stainless steel shall conform to ASTM A307;
- All other miscellaneous steel not stainless steel shall be A36;
- Threaded rod shall be ASTM F1554 GR. 105 ksi;
- All miscellaneous pipe shall conform to ASTM A53, Grade B; and
- Headed studs shall conform to ASTM A108.

8.2.6 Timber

All sawn lumber shall be minimum #1 West Coast Douglas-Fir.

All sawn lumber not in contact with water shall be incised and pressure-treated with ammoniacal copper zinc arsenate (AZCA) to 0.6 lb/ft3 in accordance with the American Wood Protection Association standard U1, Use Category 4C.

STRUCTURE-SPECIFIC ANALYSES

This page was intentionally left blank.

Attachment B
Structure-Specific Analyses
Structural Design Technical Memorandum, Swan Island Basin Project Area, Portland, Oregon

Structure	Solution	Functionality	Existing Structure/Condition Description	Key Issues		
				Geotechnical[1], Capping[2], and Riverbank[3]	Structural	Operational/Functional
U.S. Coast Guard Pier	B	Functional	• The U.S. Coast Guard (USCG) Pier is a timber pier approximately 190 feet (ft) long by 30 ft wide located on the northwestern shoreline of the SIB Project Area constructed in the 1970s. The structure comprises rows of braced vertical timber piles supporting a timber deck and incorporates a 50 ft long skiff bay at the southern end. This skiff bay has been removed from service. The pier is currently owned and operated by the USCG and is used to moor a buoy tender vessel (the Bluebell) along the eastern berth (100 ft length overall [LOA]). • As-built information for the pier and original mudline is not available. • Soil stratigraphy at the pier varies; generally comprising 25 ft of artificial fills placed landward of the pier, overlying 10 to 15 ft of medium-dense sands above 50 to 60 ft of silts/silty clay overlying a deep layer of silts.	• Existing embankment slopes do not meet the Design Criteria for slope stability. • Steeper slopes, cut to maintain the historically designed eastern berth pocket depth, would not meet the Design Criteria for slope stability.	• The pier is a timber structure. • The impacts of constructing riprap armored cap above existing sediment include increased pile shear forces by up to 65 percent when subject to 1:475 seismic inertial shaking and increased pile shear forces and bending moments by more than 200 percent when subject to a berthing impact load from the Bluebell vessel.	• The eastern berth, which services the Bluebell requires a dredge depth of -7 ft for continued operation as required by the USCG.
U.S. Navy Pier	A	Functional	• The U.S. Navy (USN) Pier is a timber berthing structure approximately 350 ft long by 30 ft wide connected to the northern shoreline of Swan Island Basin (SIB) by a 110 ft long land span constructed in the 1970s. The structure comprises rows of vertical and battered timber piles supporting a timber deck. The land span comprises vertical timber piles supporting the timber deck. The pier is currently owned by the USN and has been classified as in "Layup" status by the USN. • Limited as-built information indicates an original variable-angle riprap armored revetment with an average slope of 2.5 horizontal to vertical ratio (H:V) beneath the structure extending to a berth pocket depth of approximately -20 ft. • Soil stratigraphy at the pier varies generally comprising 25 ft of artificial fills placed landward of the pier overlying 10 to 15 ft of medium-dense sands above 50 to 60 ft of silts/silty clay overlying a deep layer of silts.	• Existing embankment slopes generally meet the Design Criteria for slope stability, however there are areas that require re-grading.	• The pier is a timber structure. • Constructing riprap armored cap above existing sediment increases land span pile shear and bending demands by 10-25percent and batter pile demands by more than 30percent when subject to 1:475 seismic inertial shaking.	• The existing pier is currently classified by USN as in "Layup" status.
Marine Consortium Pier	B	Functional	• The Marine Consortium, Inc. (MC) Pier is a timber pier approximately 80 ft long by 24 ft wide with a 124 ft wide by 30 ft long pier-head located on the northern shoreline of SIB estimated to have been constructed in the 1970s. The pier comprises rows of braced vertical timber piles supporting a timber deck. The pier is currently owned and operated by the Marine Consortium, Inc. and is used by vessels ranging from 26 to 36 ft LOA, two aluminum barges, and floating docks east and west of the fixed pier-head for the moorage of smaller vessels. • As-built information for the pier and original mudline is not available. Existing ground levels indicate that original ground profiles were likely graded to approximately 2.15H:1V extending to an existing berth pocket depth of approximately -15 ft. • Soil stratigraphy at the pier varies generally comprising 25 ft of artificial fills placed landward of the pier overlying 10 to 15 ft of medium-dense sands above 50 to 60 ft of silts/silty clay overlying a deep layer of silts.	• Existing steep embankment slopes do not meet the Design Criteria for slope stability. • Regrading of slopes to meet the Design Criteria for slope stability would negatively impact the operations of the structure.	• The pier is a timber structure. • The impacts of flattening the slope to improve slope stability by backfilling and armoring around the existing piles include increased shear demands in timber piles when subject to 1:475 seismic inertial shaking and berthing impacts.	• The existing berth pocket depth is approximately -15 ft at the existing berth line.

Attachment B
Structure-Specific Analyses
Structural Design Technical Memorandum, Swan Island Basin Project Area, Portland, Oregon

Structure	Solution	Functionality	Existing Structure/Condition Description	Key Issues		
				Geotechnical[1], Capping[2], and Riverbank[3]	Structural	Operational/Functional
Dredge Base	B	Functional	• The Dredge Base is a timber approach trestle approximately 100 ft long by 16 ft wide with a 24 ft wide by 18 ft long end platform located on the northern shoreline of SIB. The timber structure was constructed in the 1970s and provides access to two large floating docks. The structure comprises rows of braced vertical timber piles supporting a precast concrete deck with an asphaltic topping. The pier is currently owned and operated by the Port of Portland and the associated floating docks are used to moor vessels from Dredge Oregon, support barges, and tugboats. • Limited as-built information indicates an original dual-sloped, rock armored revetment at 2.5H:1V beneath the pier extending to a berth pocket depth of approximately -10 ft. • Soil stratigraphy at the pier varies generally comprising 25 ft of artificial fills placed landward of the pier overlying 10 to 15 ft of medium-dense sands above 50 to 60 ft of silts/silty clay overlying a deep layer of silts.	• Existing embankment slopes generally meet the Design Criteria for slope stability, however there are small areas that require re-grading.	• The pier is a timber structure. • Existing breasting dolphins are derelict and the existing floating docks use spud piles to hold their position. • Condition and capacity of existing up-slope mooring points is unknown.	• The berth supports two floating docks that require a dredge depth of -10 ft. • Existing breasting dolphins and up-slope mooring points require removal to implement the RA.
Berth 311	B	Functional	• Berth 311 is a timber structure approximately 450 ft long by 45 ft wide connected to the northern shoreline of SIB by two 170 ft long by 24 ft wide land spans constructed in the 1960s. The structure has rows of timber frames at 15 ft centers each comprised of vertical piles with diagonal bracing that supports a reinforced concrete deck over timber beams and joists. Unidirectional batter piles extend from mid-level frame elements to provide lateral stiffness to berthing impact loads. Land spans comprise bents of near vertical batter piles set apart at regular spacings along the length of the land spans with mid-height bracing providing longitudinal resistance. The berth is currently owned and operated by Swan Island Dock Company and is used to moor multiple vessels associated with their barge related work. • Limited as-built information indicates an original revetment slope of 3H:1V, extending to the berth pocket. • Soil stratigraphy at the pier varies, generally comprising 25 ft of artificial fills placed landward of the berth overlying 10 to 15 ft of medium-dense sands above 50 to 60 ft of silts/silty clay overlying a deep layer of silts.	• A constant slope graded to 3H:1V to match the as-built slope meets the Design Criteria for slope stability.	• The pier is a timber structure. • The impacts of constructing a capping layer above existing sediment include increased vertical pile bending demands by 15-45percent and increased batter pile bending demands by 20-25percent when subject to 1:475 seismic inertial shaking.	• The berth services barges that a navigation depth of -20 ft.
Swan Island Boat Ramp	A	Functional	• The Swan Island Boat Ramp is a 20 ft wide reinforced concrete boat ramp approximately 140 ft long located on the southeastern most bank of SIB. There are seven boarding floats located on the northwestern side of the ramp, each 20 ft long by 6 ft wide, constructed of precast reinforced concrete and moored in place by five plumb timber mooring piles. • As-built information is not available, however the ramp terminates at approximately +4 ft and the slope of the ramp and adjacent shoreline is approximately 7H:1V.	• Existing embankment slopes are stable.	• Boarding floats will need to be temporarily relocated to accommodate the RA.	• Boarding floats will need to be temporarily relocated to accommodate the RA.

Attachment B
Structure-Specific Analyses
Structural Design Technical Memorandum, Swan Island Basin Project Area, Portland, Oregon

Structure	Solution	Functionality	Existing Structure/Condition Description	Key Issues		
				Geotechnical[1], Capping[2], and Riverbank[3]	Structural	Operational/Functional
Wind Tunnel	A	Functional	• The Wind Tunnel is a testing facility located at the end of the basin on the southeast inland side of Swan Island constructed in the early 2000s. The facility is supported on three steel frames/pile bents consisting of either two or four steel pipe piles and steel girders spanning east-west between piles in each bent. • As-built information for the structure and original mudline is not available. However, existing ground-levels indicate that original ground profiles were likely graded to approximately 3H:1V extending from a steel H-pile retaining wall near the crest of the slope to a depth of approximately -5 ft. • Soil stratigraphy comprises 20 to 25 ft of artificial fills placed landward of the pier, overlying 5 to 20 ft of medium-dense sands above 20 to 25 ft of silts/silty clay overlying a deep layer of sands.	• Existing embankment slopes are marginal and require re-grading to meet the Design Criteria for slope stability.	• Condition and capacity of the existing up-slope retaining wall is unknown and excavation in front of the wall should be avoided.	• There is no navigational depth requirement, and it is understood there has not been a depth requirement for this location in SIB.
Berth 308	E	Non-Functional	• The existing Berth 308 pier is a timber structure 84 ft long by 16 ft wide with a 72 ft wide by 14 ft deep pier-head at their northern-most extent. The pier is located on northeastern bank of Swan Island approximately equally spaced between Pier 307 and the Wind Tunnel. The structure comprises vertical timber piles with mid-height bracing supporting a concrete deck. Berth 308 is owned by the Port of Portland and is understood to not be in use. The pier includes four separate breasting dolphins constructed from timber batter piles and a number of up-slope mooring points shared between Berth 307 and Berth 308. • Limited as-built information indicates that the berth had an original riprap armored revetment with an average slope of 1.75H:1V extending to a berth pocket depth of approximately -15 ft. • Soil stratigraphy varies, and generally comprises 20 to 25 ft of artificial fills placed landward of each pier, overlying 5 to 20 ft of medium-dense sands above 20 to 25 ft of silts/silty clay overlying a deep layer of sands.	• Existing embankment slopes are over steep and do not meet the Design Criteria for slope stability. • Regrading of slopes to meet the Design Criteria for slope stability would require the existing berth line to move waterward by approximately 45 ft.	• The berth and dolphins are timber structures.	• Structure is non-functional. • Slope crest is constrained with existing buildings and parking/operational areas.
Berth 306 and Berth 307	C	Functional	• The existing Berth 306 and Berth 307 piers are identical timber structures each 84 ft long by 16 ft wide with a 72 ft wide by 14 ft deep pier-head at their northern-most extent. The piers are located on the northeastern bank of Swan Island approximately equally spaced between Lagoon Wharf and Berth 308. Each structure comprises vertical timber piles with mid-height bracing supporting a concrete deck. Berths 306 and 307 are owned by Project Fleet Owner LLC and operated by Vigor and are regularly used. Each pier is accompanied by four breasting dolphins constructed from timber batter piles and a number of up-slope mooring points shared between the two berths. • Limited as-built information indicates that each berth had an original riprap armored revetment with an average slope of 1.75H:1V extending to a berth pocket depth of approximately -15 ft. • Soil stratigraphy for each pier varies and generally comprises 20 to 25 ft of artificial fills placed landward of each pier overlying 5 to 20 ft of medium-dense sands above 20 to 25 ft of silts/silty clay overlying a deep layer of sands.	• Existing embankment slopes are over steep and do not meet the Design Criteria for slope stability. • Regrading of slopes to meet the Design Criteria for slope stability would require the existing berth line to move waterward by approximately 45 ft.	• The berth and dolphins are timber structures. • The impacts of flattening the slope to meet the Design Criteria would increase the shear demands in the timber piles beyond acceptable limits and would include the use of an upland bulkhead retaining wall. Alternatively, if the slope is regraded to meet the Design Criteria, the berth line would move waterward by approximately 45 ft and would remove the needed navigation depth of the existing structure.	• A navigation depth of -15 ft is required for the berths to operate. • Slope crest is constrained with existing buildings and operational areas.

Attachment B
Structure-Specific Analyses
Structural Design Technical Memorandum, Swan Island Basin Project Area, Portland, Oregon

Structure	Solution	Functionality	Existing Structure/Condition Description	Key Issues		
				Geotechnical[1], Capping[2], and Riverbank[3]	Structural	Operational/Functional
Lagoon Wharf (Berths 302 - 305)	C	Functional	• The Lagoon Wharf includes Berths 302, 303, 304, and 305. The structure is a marginal wharf approximately 2,030 ft in length, located on the northern shoreline of Swan Island, originally constructed in 1955 with various alterations and extensions made over the years. The wharf comprises an original 52 ft wide by 1,500 ft long structure, constructed in 1955, and a 76 ft wide by 530 ft long extension constructed in 1965. Both structures comprise bents of vertical and batter timber piles spaced at 15 ft centers along the wharf's length, supporting a timber deck finished with asphaltic concrete. The wharf supports elevated quay cranes which operate over its full length. The structure is currently owned by Project Fleet Owner LLC and operated by Vigor. The cranes transfer equipment used in ship repair or vessel equipment, such as turbines, generators, motors, shafts, screws, etc. to be repaired or refurbished in Vigor shops. • Limited as-built drawings show the original foundation comprising a vertical sheet piled bulkhead wall at the back of the wharf supporting a retained height of approximately 13.5 ft, an under-wharf embankment slope of approximately 1.75H:1V, a sheet-pile toe wall accommodating a vertical step of approximately 11.5 ft, and a 1.75H:1V slope extending to a berth pocket depth of -26 ft. • Soil stratigraphy across the SIB Project Area varies and generally comprises 25 ft of artificial fills placed landward of the wharf, overlying 10 ft of medium-dense sands above 30 ft of silts/silty clay overlying a deep layer of medium to dense sands.	• As-built and current under-wharf slopes are over steep and do not meet the Design Criteria for slope stability. • A deep-seated slope failure surface exists, which does not meet the Design Criteria for slope stability in the static or seismic conditions (global stability). • Under-wharf embankment slopes, sheet-piled toe-walls, and sheet-piled bulkhead walls are unstable when subject to the CLE seismic event, when both global and local stability checks are examined. • Liquefaction and lateral spreading issues exist for the fill and sand layers that would cause slope failure, failure of the bulkhead walls,	• The wharf is a timber structure with a concrete deck.	• The wharf is operational and used by Vigor for their ship building and repair operations. A navigation depth of -26 ft is required at the existing berth line of Lagoon Wharf.

Structure-Specific Analyses
Structural Design Technical Memorandum, Swan Island Basin Project Area, Portland, Oregon

Structure	Solution	Functionality	Existing Structure/Condition Description	Key Issues		
				Geotechnical[1], Capping[2], and Riverbank[3]	Structural	Operational/Functional
Pier A	A	Functional	• Pier A is a closed-cell cofferdam pier approximately 940 ft in length located on the northern shoreline of Swan Island constructed in the 1940s. The structure comprises a finger pier approximately 635 ft in length that extends beyond the Quay Wall with the remaining ~305 ft of structure functioning as a continuous Quay Wall berth between Pier A and Lagoon Wharf. The structure is currently owned by Project Fleet Owner LLC and operated by Vigor. It is used to moor Drydock 5 on the southern berth and as a general ship berth to the north. The pier supports elevated quay cranes which operate over the length of the structure. • The pier comprises 19 closed diaphragm-cells, 3 circular closed-cells and 2 closed-cells all constructed from sheet piles. It is understood that the original design included 28 diaphragm cells, 8 of which failed during construction and were replaced with 3 circular cells. • The finger pier comprises 18 closed diaphragm cells each approximately 33.6 ft in length. A closure cell with a theoretical diameter of approximately 44 ft closes the western end of the finger pier. • The Quay Wall berth is constructed from three circular sheet-piled cells, each with a theoretical diameter of approximately 70 ft, spaced at 75 ft on center with intermediate cells arching between primary cells (one diaphragm cell and a closer cell.) • All cells are backfilled and support a cast-in-place reinforced concrete deck. Timber fender piles are present along each berth line to allow for berthing/mooring of vessels. • Limited as-built drawings indicate an original berth pocket depth of approximately -25 ft along the northern berth line and an original berth pocket depth of approximately -42 ft along the southern berth line. • Soil stratigraphy across the SIB Project Area varies, generally comprising 25 ft of artificial fills overlying 10 ft of medium-dense sands above 30 ft of silts/silty clay overlying a deep layer of medium to dense sands.	• Liquefaction potential of the backfill within the closed-cell structures could cause instability of the pier. • Cell structures are shallow, marginally stable and will not accommodate dredging against the structure deeper than originally designed.	• Dredging to a depth below the original design cannot be accommodated. Cap placement against the structure is acceptable. • The design includes monitoring the structure during construction.	Required operational depths are as follows: • Northern berth: -26 ft, • Southern berth: -49 ft (Drydock 5), and • Drydock 5 will be relocated ~50 ft southwest of Pier A and ~175 ft northwest of Quay wall.
Pier C	A	Functional	• Pier C is a finger pier approximately 1,080 ft long extending northwest from the Quay Wall. Constructed in 1952 in two segments, the east segment is 580 ft long by 50 ft wide and the west segment is 507 ft long by 34 ft wide. The two segments are integral and both comprise vertical steel pipe piles supporting a cast-in-place reinforced concrete deck constructed from a grillage of longitudinal and transverse beams supporting a topping slab. Steel H-Pile batter piles in both the longitudinal and transverse directions provide lateral restraint to berthing and mooring forces. The pier supports quay cranes and is currently owned by Project Fleet Owner LLC and operated by Vigor and used to moor Drydock 5 to the north and Drydock 3 to the south. • As-built drawings indicate original dredge depths of -45 ft beneath the 50 ft pier section and -25 ft beneath the 34 ft wide section. Retrofit drawings, dated 1962, indicate that the southern berth of the 50 ft section was deepened to -51 ft .	The existing grade is at a higher elevation than shown on the as-built drawings.	• Because the existing grade is at a higher elevation than shown on the as-built drawings, removing soil around pier piles to the originally designed soil elevation will not impact the existing structure. • Support piles extend to a deep level in the underlying soil. As such, the structure is not sensitive to minor changes in ground levels around batter piles.	Required operational depths are as follows: • -49 ft at the northeastern berth (Drydock 5), • -33 ft at the northwestern berth, • -52 ft at the southwestern berth (Drydock 3), and • -26 ft at the narrow 34 ft pier.

Attachment B
Structure-Specific Analyses
Structural Design Technical Memorandum, Swan Island Basin Project Area, Portland, Oregon

Structure	Solution	Functionality	Existing Structure/Condition Description	Key Issues		
				Geotechnical[1], Capping[2], and Riverbank[3]	Structural	Operational/Functional
Quay Wall	A	Functional	• The Quay Wall is approximately 725 ft long comprising approximately 685 ft of circular closed-cell structures and 50 ft of single sheet piles, located on the northern shoreline of Swan Island, constructed in the 1940s and 1950s. The wall retains the northern-most area of Swan Island, provides navigation depth to Drydocks 5 and 3, and the Shipyard Commerce Center (SCC) Floating Docks, and provides access to Piers A and C. • The structure includes 9 circular backfilled closed-cells constructed from sheet piles, each with an approximate diameter of 70 ft spaced at 75 ft on center, with intermediate cells arching between primary cells. Limited information is available about the original construction. • The northernmost three cells (cells A-C) were constructed in the 1940s with Pier A. At the time, four cells were constructed, originally labelled cells CC, DD, EE, and FF. • The remaining six cells (cells D through I) were constructed in the early 1950s. At this time, the original cell FF was removed to accommodate the construction of Cell D. • Cell heights vary most being approximately 105 ft in length. However, cell C is approximately 99 ft in length and cell I is approximately 70 ft in length. • Original ground levels varied from -42 ft adjacent Pier A to -18 ft adjacent cell FF to approximately 0 ft at cell I to maintain consistent cell embedment depths. • Ground levels were graded at 10H:1V from Quay Wall levels to the original drydock berth depth of -50 ft. • Existing information is contradictory. Some sources indicate original depths adjacent Pier A as low as -42 ft (80 ft total depth); other sources indicate -34 ft (72 ft total depth). • Soil stratigraphy across the SIB Project Area varies, generally comprising 25 ft of artificial fills, overlying 10 ft of medium-dense sands above 30 ft of silts/silty clay overlying a deep layer of medium to dense sands.	• Liquefaction potential of the backfill within the closed-cell structures could cause instability of the pier. • Cell structures are shallow, marginally stable and will not accommodate dredging against the structure deeper than originally designed.	• Dredging to a depth below the original design cannot be accommodated. Cap placement against the structure is acceptable. • The design includes monitoring the structure during construction.	Required operational depths are as follows: • Drydock 3: -52 ft, • Adjacent the Quay Wall between Pier A and Pier C (within Drydock 5): -49 ft, and • Drydock 5 can be relocated ~50 ft southwest of Pier A and ~175 ft northwest of Quay wall.
SCC Floating Dock	A	Functional	• The SCC Floating Dock is located to the south of Pier C directly adjacent the southern extents of the Quay Wall and provide moorage to Vigor's small craft fleet. The northernmost dock is approximately 160' long and the southernmost is approximately 400 ft long; both docks are 8 ft wide. 14 steel pipe mooring piles are used to moor the docks in position and access is provided by an aluminum gangway hinged from a bulkhead wall supporting the embankment. • Existing slopes beneath the floating docks, which extend from the crest adjacent the existing silo area, vary between approximately 1.75H:1V to 4H:1V.	• A regraded constant slope, graded to 2.75H:1V would suit the navigation requirements and existing crest levels and would meet the Design Criteria for slope stability if constructed using new riprap armor.	• Boarding floats will need to be temporarily relocated to accommodate the RA. • Guide piles can remain and RA work can be done around them.	• No specific navigation requirements exist for the floating docks above maintaining the existing drafts.

Structure-Specific Analyses
Structural Design Technical Memorandum, Swan Island Basin Project Area, Portland, Oregon

Structure	Solution	Functionality	Existing Structure/Condition Description	Key Issues		
				Geotechnical[1], Capping[2], and Riverbank[3]	Structural	Operational/Functional
East Pier	A	Functional	• East Pier is an elevated gangway structure connected to the bank of Swan Island and extending waterward to the northwest. The structure was constructed in the 1970s. The structure comprises a two-span fixed steel truss gangway connecting the shore to a small pier and an articulating steel truss gangway connecting the small pier to the Vigorous Drydock. The pier is currently owned by Project Fleet Owner LLC and operated by Vigor. The structures impacted by the RD are an intermediate pier which supports the two-span fixed gangway and the small pier. The intermediate pier is a reinforced concrete pile cap supported by four rectangular precast batter piles. The small pier is a rectangular cast-in-place pile cap approximately 30 ft long by 22 ft wide supported on four vertical steel pipe piles. • As-built drawings are not available; however, current ground levels beneath West Pier and East Pier indicate a likely original embankment slope of approximately 2.75H:1V extending to the Vigorous Drydock berth pocket.	• Existing slopes are approximately 2.75H:1V and meet the Design Criteria for slope stability with the addition of riprap armor.	• Regrading of under-pier slopes can be tailored to maintain existing depths around pier piles and allow requested depths to be achieved outside the area of structural impact. • The structural form is not sensitive to minor changes in ground levels around batter piles.	Operational depth within the Vigorous Drydock is -56 ft; however, based on discussions with Vigor during owner/operator consultation meetings, it is understood that the existing revetment toe could move northwest if required.
West Pier	A	Functional	• West Pier is a 155 ft long by 18.5 ft wide fixed ramp structure connected to the bank of Swan Island and extending waterward to the northwest. The structure was constructed in the 1970s. The pier supports an articulating steel ramp providing vehicular access to the Vigorous Drydock. The fixed pier is a four-span reinforced concrete deck supported by and cast integrally with the three landward-most piers and is bearing supported on the fourth (western-most) pier. The pier is currently owned by Project Fleet Owner LLC and operated by Vigor. Each structural pier comprises a cast-in-place concrete pile cap supported on vertical and batter piles; the landward most two being precast rectangular piles, and the seaward two being steel pipe piles. • As-built drawings are not available; however, current ground levels beneath West Pier and East Pier indicate a likely original embankment slope of approximately 2.75H:1V extending to the Vigorous Drydock berth pocket.	• Existing slopes are approximately 2.75H:1V and meet the Design Criteria for slope stability with the addition of riprap armor.	• Regrading of under-pier slopes can be tailored to maintain existing depths around pier piles and allow requested depths to be achieved outside the area of structural impact. • The structural form is not sensitive to minor changes in ground levels around batter piles.	Depth within the Vigorous Drydock is -56 ft; however, based on discussions with Vigor during owner/operator consultation meetings, it is understood that the existing revetment toe could move northwest if required.
Demo Pier	A	Functional	• Demo Pier is a 200 ft long by 42 ft wide finger pier structure connected to the bank of Swan Island and extending waterward to the northwest. The structure was constructed in the early 1990s as an access bridge/loadout bridge to the Vigorous Drydock. The pier is currently owned by Project Fleet Owner LLC and operated by Vigor. The structure comprises eight cast-in-place reinforced concrete piers supported on vertical and batter steel pipe piles, each spaced at approximately 25 ft centers supporting, ad a cast-in-place buried abutment structure of similar construction. The superstructure comprises a grillage of steel I-girders spanning longitudinally, simply supported between piers, supporting timber decking spanning transversely across girders. A ninth superstructure span connects the ninth pier to the Drydock. • Limited as-built drawings indicate variable riprap armored under-pier ground levels, with slopes ranging from approximately 2H:1V near the abutment, 10H:1V near the middle of the, pier and 1.5H:1V at the toe.	• Existing slopes are approximately 2.75H:1V and meet the Design Criteria for slope stability with the addition of riprap armor.	• Regrading of under-pier slopes can be tailored to achieve depths around pier piles similar to as-built depths and allow requested depths to be achieved outside the area of structural impact. • The structural form is not sensitive to minor changes in ground levels around batter piles.	Operational depth within the Vigorous Drydock is -56 ft; however, based on discussions with Vigor during owner/operator consultation meetings, it is understood that the existing revetment toe could move northwest if required.

Structure	Solution	Functionality	Existing Structure/Condition Description	Key Issues		
				Geotechnical[1], Capping[2], and Riverbank[3]	Structural	Operational/Functional
Pier D	A	Functional	•Pier D is a 1,000 ft long by 56 ft wide finger pier connected to the bank of Swan Island and extending waterward to the northwest. The structure is constructed integrally with the adjoining Willamette Wharf (2,000 ft long marginal wharf) in 1979. The pier is currently owned by Project Fleet Owner LLC and operated by Vigor. This project considers the finger pier (Berth 312) only and Willamette Wharf (Berths 313 and 314) are excluded. •Pier D is a reinforced concrete structure comprising 52 bents of vertical and batter piles spaced at approximately 22.33 ft longitudinally supporting a reinforced concrete deck. Pile bents typically comprise 24-inch hollow octagonal precast concrete piles supporting cast-in-place pile caps. Piles bents comprise either vertical piles only or both vertical and transverse batter piles. Longitudinal steel battered H-Piles, located approximately every 12-15 pile bents, provide resistance to longitudinal loads. The superstructure is constructed of precast concrete deck panels spanning approximately 20 ft between cast-in-place pile caps with an 8-inch cast-in-place topping slab poured monolithically with pile caps. • Limited as-built drawings indicate a variable dredge depth along the southern berth, although indicated as typically -35 ft at the marginal wharf. Original northern berth depths appear a constant -60 ft within and west of the drydock berth. Original ground levels adjacent to Demo Pier are assumed to vary between a depth of -60 ft tending to a 2.5H:1V riprap armored revetment slope beneath the marginal wharf.	• The existing grade is at a higher elevation than shown on the as-built drawings. • Protect in place functional capacity of infrastructure.	• Regrading of berth pocket sediment can be tailored to achieve depths around pier piles similar to original depths and allow requested depths to be achieved outside the area of structural impact. • The structural form is not sensitive to minor changes in ground levels around batter piles.	Required operational depth within the northern berth pocket is -57 ft and southern berth pocket depth (Berth 312) is -30 ft. Both are approximately 3 to 5 ft shallower than as-built depths.
City of Portland Stormwater Outfalls	C	Functional	• The City of Portland's stormwater outfalls impacted by the RA include M1, M2, M3, S1, and S2. Outfall S1 is a 36-inch corrugated metal pipe through a sheet pile headwall under Lagoon Wharf. All other outfalls are concrete pipes, ranging from 36 to 60 inches in diameter, terminating with reinforced concrete headwalls around the SIB embankment. Existing concrete pipes are expected to have been manufactured in segments 7 to 8 ft long and bell-end/spigot connected on site. • Existing embankment slopes surrounding/above exiting outfalls are typically 3H:1V or shallower, except outfall S2 which is approximately 1.25H:1V to 1.5H:1V above the outfall and outfall S1 (refer to Lagoon Wharf, above).	•The existing steep embankment slope above outfall S2 does not meet the Design Criteria for slope stability.	• Outfall M3 was constructed in the late 1980s, has been observed to be in moderate condition. • All other outfalls were constructed in the 1960s are in moderate to poor condition, typically observing concrete spalling at the wingwalls and cracking with undermining of outfall toes.	Outfall piping to be extended to maintain current function along with addition of a new armored splashpad and wingwalls to accommodate grades.

Structure-Specific Analyses
Structural Design Technical Memorandum, Swan Island Basin Project Area, Portland, Oregon

Structure	Solution	Required Remedial Design[1,2,3]	Adopted Remedial Design to achieve RAOs and Structural Solution to accommodate RD		
			Description	Impacts	Analysis and Design Methodology
U.S. Coast Guard Pier	B	• Dredge the eastern berth pocket to its historical navigation depth as originally designed. • Cap existing shallow slope sediments surrounding the structure. • Install riprap armor on steeper slopes. • Grade under-structure slopes to meet Design Criteria for slope stability. • Protect the structure to preserve its operational functionality.	• New riprap armored revetment slopes installed in accordance with the selected constructible alternative at a maximum slope of 2.75H:1V • New sheet-piled toe wall constructed directly adjacent the structure to accommodate historically designed eastern berth dredge depths • Pile isolation sleeves to isolate existing pier piles from new riprap • New fender pile system, constructed seaward of the new toe wall to accommodate the Bluebell vessel	Construction of the structural remedial design measures will allow the structural performance and functionality to be maintained	• Refer to Attachment C for detailed analysis and design methodology for: o Berth pocket toe walls o Pile isolation sleeves o Relocated fender system
U.S. Navy Pier	A	• Cap existing shallow slope sediments beneath the structure. • Install riprap armor on steeper slopes. • Grade under-structure slopes to meet Design Criteria for slope stability. • Protect the structure to preserve its operational functionality.	• Selected constructible alternative installed at a maximum slope of 2.5H:1V.	The existing pier structure following implementation of the RA will perform and function as it did in the as-built configuration without the need for structural measures.	NA
Marine Consortium Pier	B	• Maintain navigational depth to allow for continued operations at the structure. • Cap existing shallow slope sediments beneath the structure. • Install riprap armor on steeper slopes. • Protect the structure to preserve its operational functionality.	• New riprap armored revetment slopes installed in accordance with the selected constructible alternative at a slope of 2.15H:1V • New mid-slope pinning walls constructed through the slope to provide static and seismic slope stability	Construction of the mid-slope pinning walls will allow the structural performance and functionality to be maintained	Refer Attachment C for detailed analysis and design methodology for the new mid-slope pinning walls

Attachment B
Structure-Specific Analyses
Structural Design Technical Memorandum, Swan Island Basin Project Area, Portland, Oregon

Structure	Solution	Required Remedial Design[1,2,3]	Adopted Remedial Design to achieve RAOs and Structural Solution to accommodate RD		
			Description	Impacts	Analysis and Design Methodology
Dredge Base	B	• Maintain existing navigation depth beneath the floating docks and at the berth line. • Dredge to RAL in front of the structure to remove contaminated sediment and allow for vessel spudding. • Grade under-structure slopes to meet Design Criteria for slope stability. • Protect the structure to preserve its operational functionality.	• New riprap armored revetment slopes installed in accordance with the selected constructible alternative at a maximum slope of 2.5H:1V to match as-built profile • Four new mooring piles with pile hoops to maintain the floating dock mooring functionality • Dredge to RAL in front of the structure to allow for spudding of vessels to maintain operational requirements	Construction of the structural remedial design measures, will allow the structural performance and functionality to be maintained	Refer Attachment C for detailed analysis and design methodology for the mooring infrastructure.
Berth 311	B	• Cap existing shallow slope sediments beneath the structure. • Install riprap armor on steeper slopes. • Dredge to RAL in front of the structure to remove contaminated sediment and allow for vessel spudding. • Grade under-structure slopes to meet Design Criteria for slope stability. • Protect the structure to preserve its operational functionality.	• New riprap armored revetment slopes installed in accordance with the selected constructible alternative at a slope of 3H:1V, to match as-built profiles beneath land spans. • New capping placed beneath the berth structure at a shallow slope constructed below existing mudline levels, closer to as-built profiles. • Dredge to RAL in front of the structure to allow for spudding of vessels to maintain operational requirements. • New breasting dolphin to accommodate barges moored alongside existing mooring dolphin to maintain barge mooring functionality and provide continuity of existing operations.	Construction of the structural remedial design measures, will allow the structural performance and functionality to be maintained	Refer Attachment C for detailed analysis and design methodology for the mooring infrastructure.
Swan Island Boat Ramp	A	• Cap existing shallow slope sediments beneath boarding floats and surrounding the ramp with selected constructible alternatives as specified in RDTM Figure 3-1 (Volume I, Appendix D). • Provide erosion protection to toe of the boat ramp.	• Selected constructible alternative placed in areas surrounding concrete ramp.	The existing ramp and boarding floats following implementation of the RA will perform and function as it does currently without the need for structural measures.	NA

Structural Design Technical Memorandum, Swan Island Basin Project Area, Portland, Oregon

Structure	Solution	Required Remedial Design[1,2,3]	Adopted Remedial Design to achieve RAOs and Structural Solution to accommodate RD		
			Description	Impacts	Analysis and Design Methodology
Wind Tunnel	A	• Cap existing shallow slope sediments beneath the structure. • Protect the structure to preserve its operational functionality.	• New riprap armored revetment slopes installed in accordance with the selected constructible alternative at a slope of 2.15H:1V.	The existing structure following implementation of the RA will perform and function as it does currently without the need for structural measures.	NA
Berth 308	E	• Cap existing shallow slope sediments. • Install riprap armor on steeper slopes.	• Demolition of existing pier and dolphin structures. • Newly graded riprap armored revetment slopes installed in accordance with the selected constructible alternative at a maximum slope of 2.5H:1V.	As the existing structure is non-functional, it will be removed to accommodate the RA.	NA
Berth 306 and Berth 307	C	• Cap existing shallow slope sediments beneath the structure. • Install riprap armor on steeper slopes. • Grade under-structure slopes to meet Design Criteria for slope stability. • Replace functional capacity of infrastructure.	• Remove and replace existing pier and dolphin structures at a new berth line further into SIB to accommodate a newly graded slope. • Newly graded riprap armored revetment slopes installed in accordance with the selected constructible alternative at a maximum slope of 2.5H:1V with berth line pushed waterward to the north • Functionally-equivalent reconstruction of Berths 306 and 307 piers with accompanying breasting dolphins and up-slope mooring points to accommodate new slope toe and berth line.	Replacement of the structures on a shallower slope will allow the current operations to continue after RA activities.	• Refer Attachment C for detailed analysis and design methodology for: o Replacement Berth Piers o Replacement Berth dolphins o Replacement Berth mooring points

ATTACHMENT C
SHORELINE AND OVERWATER STRUCTURES ANALYSIS AND DESIGN METHODOLGY

This page was intentionally left blank.

1.0 INTRODUCTION

This attachment describes the analysis and design methodology used to design structures to accommodate the Remedial Design (RD) for the Swan Island Basin (SIB) Project Area. Additionally, it outlines the evaluation of overwater structures, conducted according to the Structural Action Decision Tree (Figure 2-1 in the Structural Design Technical Memorandum), which determined the necessity for structural design (Solutions B and C).

Where the Structural Design Criteria (Attachment A) details standards of reference and performance requirements to be adhered to during design of new structures, this attachment describes the analysis methods employed to achieve compliance with the performance objects and standards identified. This attachment follows the Structure-Specific Analyses (Attachment B) which identifies the following structures to be constructed as part of and to support the Remedial Action (RA):

- U.S. Coast Guard (USCG) Pier
    - Berth pocket toe wall
    - Pile isolation sleeves
    - Functional-equivalent fender system
- Marine Consortium (MC) Pier
    - Mid-slope pinning walls
- Dredge Base
    - Functionally equivalent mooring infrastructure (mooring piles)
- Berth 306 and Berth 307
    - Functionally equivalent berth infrastructure:
        - Piers
        - Breasting Dolphins
        - Up-slope Mooring Points
- Berth 311
    - Functionally equivalent mooring infrastructure (breasting dolphin)
- City of Portland (COP) Stormwater Outfalls
    - Outfall Pipe Headwall structures
- Lagoon Wharf (Berths 302 - 305)
    - Functionally equivalent wharf infrastructure

2.0 STRUCTURAL ANALYIS MODELING INPUTS

2.1 SECTION/MATERIAL PROPERTIES

Structural analysis models were created in SAP2000 using shell elements for reinforced concrete pile caps and decks and line elements for piles. Cracking of concrete elements are accounted for by assuming cracked section properties. Steel sections are considered gross and are designed for

sacrificial corrosion loss per Attachment A. Section and material properties used are listed in Table C-1.

Table C-1 Modeling Section Properties

Element	E (Modulus of Elasticity)	Moment of Inertia $I_{x.eff}$	Moment of Inertia $I_{y.eff}$
RC pile plug	4,000 ksi	0.50 I_g	0.50 I_g
RC deck	4,000 ksi	0.50 I_g	0.50 I_g
Steel Pipe Piles	29,000 ksi	I_g	I_g

Notes:
E = Modulus of Elasticity
RC = reinforced concrete
ksi = Kilopounds per square inch
I_g = Moment of inertia (gross)
$I_{x.eff}$ = Effective moment of inertia about the x-axis
$I_{y.eff}$ = Effective moment of inertia about the y-axis

2.2 SOIL RESTRAINT TO PILES

Reference the Geotechnical Design Technical Memorandum (GDTM) (Volume I, Appendix I) for soil parameters and information related to foundation elements.

Lateral restraint to embedded piles was modeled with non-linear Winkler springs using force-displacement (P-Y) curves provided in the GDTM. Non-linear two-joint links in SAP2000 were placed at 3-foot intervals along the pile height. Static soil springs were used to assess gravity load conditions including dead, live, berthing, and mooring loads. Cyclic soil springs were used to assess seismic effects. Bilinear soil springs accounted for piles on slopes that varied stiffness and capacity by load direction. Pile group effects on spring stiffnesses and capacities followed GDTM guidelines.

Vertical restraint to embedded piles was modeled using a roller pinned connection. Torsional restraint was excluded except for single-pile models.

3.0 DESIGN OF STRUCTURAL ELEMENTS

Structural elements were designed to withstand the load and force demands developed by the structural analyses.

3.1 STEEL PILE PIPES

Steel pipe piles were designed per AASHTO Section 6.9.2.2.1 for the combined action of axial and flexural effects. Piles are designed as elastic when subject to all static load combinations and designed as yielding elements when subject to the Design Earthquake (DE). The following non-linear properties were used in accordance with ASCE 61-14:

- F_{ye} = 55,000 pounds per square inch (psi)
- Φ = 1.0
- Strain limit for the DE = 0.05 inch/inch

3.2 STEEL SHEET PILES

Sheet pile walls were designed using the U.S. Army Corps of Engineers Engineer Manual: Design of Sheet Pile Walls (USACE EM 1110-2-2504). Sheet piles are designed to be elastic when subject to static and Contingency Level Earthqauke (CLE) load combinations.

3.3 REINFORCED CONCRETE PILE PLUGS

Reinforced concrete pile plugs at the top of steel pipe piles were designed to ACI 318 Section 22.4 for combined actions of axial and flexural effects. Piles are designed to be elastic when subject to static load combinations and designed as yielding elements when subject to the DE. The following non-linear properties were used in accordance with ASCE 61-14:

- F'_{ce} = 6,500 psi
- F_{ye} = 66,000 psi
- Φ = 1.0
- Strain limit for DE (concrete) = No limit
- Strain limit for DE (reinforcement) = 0.064 inch/inch

3.4 REINFORCED CONCRETE PILE CAP AND DECKS

Reinforced concrete pile cap elemtns and deck were designed to AASHTO Section 5.6 for combined actions of axial and flexural effects. Concrete geometry and steel reinforcement was sized for the flexural tension stress limits of AASHTO clause 5.6.7 when subject to SLS load combinations. Elements were designed to remain elastic for all static ULS load effects and were designed as capacity protected in accordance with ASCE 61 using overstrength actions from yielding elements.

4.0 U.S. COAST GUARD PIER

4.1 EVALUATION OF OVERWATER STRUCTURE

- Geotechnical slope stability analysis was conducted for the under-structure and structure adjacent slopes. It was concluded that a maximum slope angle of 2.75H:1V is necessary to meet the design criteria for slope stability.
- Given the navigation requirement to provide a berth depth of approximately -6.75 ft in the eastern berth pocket for the Bluebell vessel, a constant slope from berth pocket depth to the existing crest level would be approximately 2H:1V, which does not satisfy slope stability requirements.
- To meet slope stability requirements, a final capped slope of 2.75H:1V was adopted from the top of the existing crest and combined with a new toe wall constructed along the berth line of the pier to accommodate a vertical cut to meet navigation needs.
- To accommodate a 2.75:1V slope, up to 4 ft of fill and riprap armor layers are added on top of the current slope.

- The effects on the existing structure of the additional fill material were examined by performing comparative structural analyses of the pier structure in both the current and final condition.
    - A three-dimensional (3-D) analysis model was created using SAP2000 (Figure C-1), modeling all primary timber elements as line elements and the geotechnical support conditions as an equivalent depth-to-fixity.
    - The depth to fixity was determined to be 6 ft within the existing clay layers and 5 ft within existing fill layers. Following the completion of the RA, the depth to fixity was estimated to be within 4 ft from the top of the finished riprap surface.
    - Each model was analyzed for the effects of uniformly applied lateral loads, berthing impact point loads, and seismic inertial forces using a response spectrum analysis adopting the site-specific CLE response spectra.
    - Impacts on the structure included increased pile shear forces by up to 65% due to CLE inertial shaking and increased pile shear forces and bending moments by more than 200% due to a berthing impact point load.
- To mitigate the negative impacts to the existing structure, it was determined that piles will need to be isolated from the new cap layer using pile sleeves. Details for these pile sleeves are included in the RD drawings.

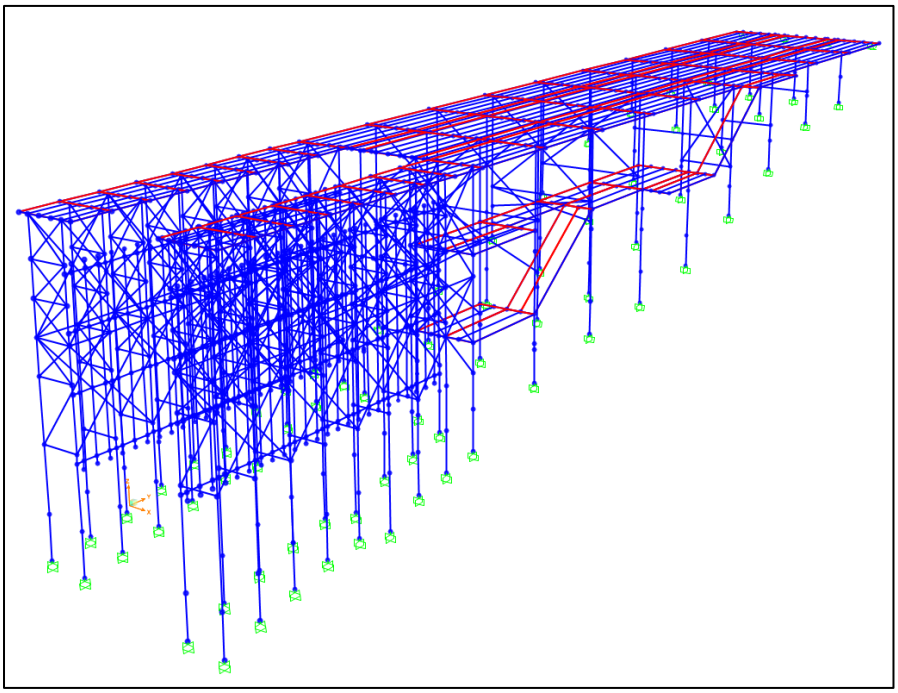

Figure C-1. Analysis model of USCG Pier

4.2 BERTH POCKET TOE WALL

A new toe wall is required to maintain the functionality and operability of the pier, which is used by the Bluebell vessel, while ensuring that the surrounding slopes remain stable per the project's design criteria. To accommodate the navigation depth, the thickness of the chemical isolation cap,

future dredge allowance within the berth pocket, and finished riprap elevation above the wall, a maximum retained height of 17 ft for a temporary condition prior to cap placement and a final retained height of 12 ft were considered for the wall design.

4.2.1 Structural Form

The new toe wall is a driven sheet pile wall constructed from pre-manufactured mild steel sheet pile sections, driven and clutched together to form a continuous wall. The wall cantilevers from the underlying strata and the ratio of the embedded length of wall to free length in approximately 2:1.

4.2.2 Analysis and Design

The wall was analyzed using the DeepEx software program for static, CLE, and DE load combinations with analysis results provided for structural design. The wall was engineered to limit maximum static displacement to 2 inches, thereby safeguarding and mitigating adverse impacts on the existing pier piles.

Sheet piles were designed for the flexural and shear demands provided by the DeepEx analysis. Hot-rolled steel ‘Z’ Section sheet piles, like Nucor NZ 38, were found to be adequate for the toe wall.

4.3 PILE SLEEVES

Pile sleeves are added to separate existing pier piles from the new riprap revetment. These sleeves prevent the added revetment from putting loads on the timber piles and help mitigate adverse effects associated with increased effective depth to pile fixity. Furthermore, pile sleeves serve to isolate the piles from passive loads resulting from any lateral movement of the cap during seismic events.

4.3.1 Structural Form

Pile sleeves are designed as steel pipe sections conforming to standardized Schedule 40 pipe specifications. These sleeves are fabricated in two halves, complete with bottom flanges, that are anchored into the existing grade surface, to allow for fitting around existing pier piles prior to the placement of new riprap armoring.

4.3.2 Analysis and Design

The following details the design of the pile sleeves:

- Each sleeve is held in place by the riprap armor layer.
- The pile sleeves are dimensioned to provide a minimum clear annulus of 1.25 times the expected long-term toe wall displacement (2 inches), providing isolation from the riprap should the anticipated movements of the toe wall occur.
- Each sleeve is anchored to the excavated slope face and separated from the pier piles with temporary spacers during the construction of the riprap armoring. Upon completion of the

riprap placement, the temporary spacers will be removed and a debris cap installed at the top to keep debris out of the annular space. Drawdown due to sheet pile installation was not considered, but the RA Contractor should include drawdown effects in the final design and analysis.

4.4 FENDER SYSTEM

To accommodate construction of the new toe wall, existing timber fender piles will be removed. New fender piles will be installed seaward of the new toe wall for fendering operations.

4.4.1 Structural Form

New steel pipe fender piles have been designed to provide energy absorption characteristics equal to or greater than what is expected to be provided by the existing timber fender piles. New extruded rubber fendering is provided along the berth line, provide a loading path between fender piles and the pier similar to the existing condition, and provide energy absorption.

4.4.2 Analysis and Design

The energy absorption capacity of existing timber fender piles was evaluated by determining the flexural resistance of the piles and expected displacement when loaded with a point load near their mid-height. Existing piles were evaluated as propped cantilevers, assuming a nominal depth to fixity within the existing strata.

New steel pipe piles were evaluated using the same methodology to determine the energy absorption capacity assuming a deeper depth to fixity accounting for the dredge berth pocket and larger pile diameter. The spacing of new fender piles was selected to match existing pile spacings to accommodate the Bluebell's hull shape and various berthing conditions.

5.0 MARINE CONSORTIUM PIER

5.1 EVALUATION OF OVERWATER STRUCTURE

- Geotechnical slope stability analysis was conducted for the under-structure and structure adjacent slopes, concluding that a maximum slope angle of 2.75H:1V is necessary to meet the design criteria for slope stability.
- Given the navigation requirement to provide a berth depth of approximately -18.75 ft in front of the pier and along the adjacent shoreline, a constant slope from berth pocket depth to the existing crest level would be approximately 2.15H:1V, which does not satisfy slope stability requirements.
- Existing grades beneath the pier are close to and indicate an original slope angle of 2.15H:1V. Therefore, functionality and performance of the structure can be maintained by maintaining a 2.15H:1V slope angle.
- To accommodate a slope of 2.15H:1V, ground improvements are required to avoid slope instability in both the static and seismic conditions. Geotechnical analysis conducted with the slope stability software package Slide concluded that both deep-seated failure and

shallow failure of the 2.15H:1V slope is possible in each of the events. Refer to the GDTM for further information.

- Additional geotechnical analysis was completed using Slide which demonstrated that deep-seated failure could be mitigated by a single row of mid-slope pinning walls, however shallow failure was still possible in front of or behind a single wall. Therefore, two rows of mid-slope pinning walls were adopted.
- Refer to the GDTM for further information regarding the geotechnical analyses.

5.2 MID-SLOPE PINNING WALLS

5.2.1 Structural Form

New mid-slope pinning walls are driven sheet pile walls constructed from pre-manufactured mild steel sheet pile sections, driven and clutched together to form a continuous wall. Each wall is approximately 80 to 100 ft in length and resists kinematic forces from slope movements through out-of-plane flexural action.

5.2.2 Analysis and Design

An iterative soil-structure interaction analysis and design process was employed to develop the pinning walls as follows:

- Detailed geotechnical analyses of the proposed mid-slope pinning walls were conducted using the software package Slide. These analyses determined free-field slope displacements of the 2.15H:1V slope following the CLE, which were approximately 0.67 ft. Refer to the GDTM for additional details.
- A two-dimensional analysis model was created using SAP2000 software (Figure C-2) with each wall modeled as a line element representing a linear foot width of the wall. Geotechnical restraint was modeled using non-linear PY-links developed by the geotechnical team.
- Free-field slope displacements were applied to non-linear links above the elevation of the expected slip surface as predicted by the Slide analysis. The resulting design displacements and flexural actions of the wall were summarized.
- Shear resistance values obtained from the SAP2000 analysis were incorporated into the Slide analysis model to provide resistance against slope failure. This resulted in a pinned slope displacement of approximately 0.5 ft.
- The analysis and design process was repeated iteratively until convergence between displacements and pinning resistances was achieved, with final displacements being approximately 0.6 ft.
- Sheet piles were designed in accordance with Section 3.0 utilizing the flexural and shear demands derived from the SAP2000 analysis for a 0.60 ft displacement. Hot-rolled steel ‘Z’ section sheet piles, like Nucor NZ 38, were found to be adequate for the pinning wall.

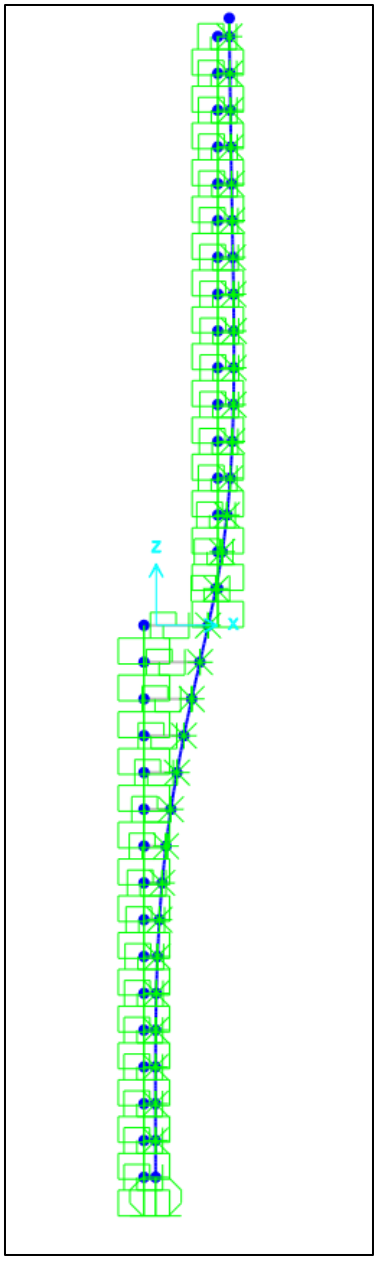

Figure C-2. SAP2000 model of mid-slope pinning wall displaced shape

6.0 DREDGE BASE

6.1 EVALUATION OF OVERWATER STRUCTURE

- Geotechnical slope stability analysis was conducted for the under-structure and structure adjacent slopes concluding that a maximum slope angle of 2.50H:1V is necessary to meet the design criteria for slope stability.
- Given the navigation requirement to provide a berth depth of approximately -10 ft in front of the fixed pier and along the adjacent shoreline, a constant slope from berth pocket depth to the existing crest level would be approximately 2.50H:1V.

- As-built grades beneath the pier structure indicate an original slope angle of 2.50H:1V with a mid-slope bench, and current bathymetry indicates only minor sedimentation directly beneath the pier. Therefore, functionality and performance of the pier structure can be maintained by maintaining a 2.50H:1V slope angle.
- The current mooring infrastructure for the Dredge Base's two floating docks that are permanently moored at the Dredge Base includes spud piling of the dredge base floats, damaged breasting dolphins, and up-slope mooring points.
- Existing up-slope mooring points and breasting dolphins need to be removed to allow for clearing, grubbing, dredging, and regrading of the slopes at and on either side of the pier.
- Functionally equivalent mooring infrastructure has been designed to replace the existing breasting dolphins and up-slope mooring points.

6.2 FUNCTIONALLY EQUIVALENT MOORING INFRASTRUCTURE

A mooring analysis was completed in accordance with Attachment A to determine mooring geometry requirements and mooring forces for the design of functionally equivalent mooring infrastructure.

Final infrastructure geometry includes provision of four new permanent mooring piles complete with pile hoops retrofitted to the existing floats.

6.2.1 Structural Form

New mooring piles are plumb steel pipe piles driven into the underlying soil located directly landward of the existing dredge floats. Two mooring piles are provided per float. Pile hoops will be designed and fabricated to suit the existing barge hulls and pile hoops will be releasable to accommodate future movement/relocation of the barges, if required.

6.2.2 Analysis and Design

A 3-D analysis model was created using SAP2000. The steel pile was modeled using line elements. Material and section properties adhere to Table C-1. The typical elevation at the top of the pile is approximately +35 ft, where the ground elevation is approximately -10 ft.

Mooring loads were applied to the analysis model in accordance with Attachment A using concentrated loads applied at various horizontal and vertical angles. Dead loads were included in the analysis model using the SAP2000 built-in self-weight function which calculates dead loads based on element geometry and material densities. Seismic effects do not control by inspection.

The design of structural elements follows Section 3.0 utilizing the flexural and shear demands derived from the SAP2000 analysis.

7.0 BERTH 306 AND BERTH 307

7.1 EVALUATION OF OVERWATER STRUCTURE

- A geotechnical slope stability analysis was conducted for the embankment slope extending from Lagoon Wharf to Wind Tunnel, which includes Berth 306 and Berth 307. It concluded that a maximum slope angle of 2.50H:1V is needed to adhere to the design criteria for slope stability.
- The existing embankment slope varies along its length but has an average slope angle of 1.75H:1V. To maintain operation of Berth 306 and Berth 307, a navigation depth of -14.75 ft extending approximately 1,200 ft east of Lagoon Wharf is required.
- To accommodate a steeper slope of 1.75H:1V, significant ground improvements are required to mitigate global and local slope instability under both static and CLE conditions. Geotechnical analysis using the Slide software package concluded that both deep-seated and shallow failure of the 1.75H:1V slope are likely in each event.
- Geotechnical analysis was performed using the Slide software to evaluate ground improvement concepts including mid-slope pinning walls and stepped retaining walls. However, given the oversteep slope and extent requiring improvement, preliminary cost comparisons demonstrated that flattening the slope is more economical.
- To accommodate a flatter slope while meeting navigation requirements, the existing berth and dolphin structures will need to be demolished and reconstructed at the new berth line of the flatter slope to maintain functionality.

7.2 FUNCTIONALLY EQUIVALENT REPLACEMENT STRUCTURES

The geometry and arrangement of replacement piers, breasting dolphins, and up-slope mooring points were designed to correspond with the existing structures' locations and functions. The developments include:

- Two new pier structures (Berths 306 and 307) located at the new berth line
- Nine new breasting dolphins (five at Berth 306 and four at Berth 307) each furnished with conventional mooring bollards and vertical fendering. Two dolphins include shore access provided by two-span gangways
- Nine new up-slope mooring points furnished with conventional mooring bollards and distributed along the crest of the embankment slope.

Mooring and berthing analyses were conducted in accordance with Attachment A to determine the forces for the design of the replacement breasting dolphins and mooring points.

7.3 BERTH 306 AND BERTH 307 PIERS

7.3.1 Structural Form

The replacement Berth 306 and Berth 307 structures are pile supported structures which extend from the crest of the flattened embankment slope towards the new berth line that is approximately 45 ft waterward of the existing berth line. Each berth comprises 16 vertical steel pipe piles, approximately 30-inches in diameter that support a variable thickness cast-in-place reinforced concrete deck. Each pier is approximately 112 ft long by 16 ft wide with a 17 ft long by 70 ft wide pier head at the berth line. A uniform thickness deck, approximately 18 inches thick spans between pile bents, and thickened pile caps span east-west over pile bents. Landside structures include a cast-in-place concrete retaining wall supporting engineered backfill beneath a deck-supported concrete approach slab.

7.3.2 Analysis and Design

A 3-D analysis model was created using SAP2000 (Figure C-3). The model represents both Berth 306 and Berth 307 due to the similarity in subsurface soil conditions and geometry. The deck structure is modeled using shell elements connected to concrete plug elements and steel pipe piles via rigid links from the mid-depth to the soffit of the deck. Pile plugs and steel pipe pile elements are modeled using line elements. Material and section properties adhere to Table C-1. The typical elevation at the top of the deck is approximately +38.5 ft. The revetment elevation ranges from +36 ft at the landward most pile row to –15 ft at the seaward most pile row. Note, the basin depth is approximately 15 ft to 17.5 ft at Berths 306 and 307.

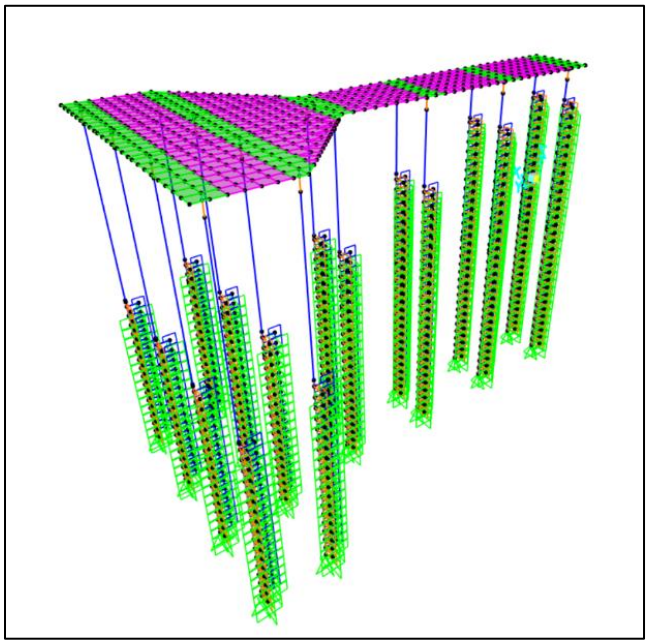

Figure C-3. SAP2000 model screenshot of Berths 306 and 307

Live loads were applied to the analysis model in accordance with Attachment A using pressure and concentrated load assignments. Dead loads were included in the analysis model using the

SAP2000 built-in self-weight function which calculates dead loads based on element geometry and material densities.

Seismic effects from the DE were assessed in SAP2000 using the ASCE-61 displacement-based design method B as follows:

- Plastic hinge properties were calculated and modelled in SAP2000.
- Pile plugs were expected to form plastic hinges at the underside of the deck when subject to inertial and kinematic demands.
- Steel pipe pile plastic hinges were expected to form deep in the ground when subject to kinematic demands.
- A capacity curve (base shear – displacement) was created for the berth structure utilizing a non-linear static pushover analysis. The capacity curve plots the change in base shear versus the structure's center of mass displacement when subject to an increasing horizontal acceleration, and accounts for elastic and inelastic deformation of the ground conditions and hinging elements.
- The DE event response spectrum was used to determine the performance point through iteration. From this analysis, a design displacement is created which can be applied to the structure.
- This process was repeated in both orthogonal plan directions (i.e., north-south and east-west in plan).
- Design displacements in both orthogonal directions were combined in accordance with ASCE 61-14.

The detailed geotechnical slope stability analysis of the new 2.5H:1V embankment slope has indicated that the pseudo-static slope stability factor of safety is less than 1.0. This suggests that earthquake-induced lateral ground deformations of the embankment are likely, and the new berths need to be designed accordingly. A free-field displacement of 2 ft is anticipated at a maximum depth of -40 ft. The typical pushover curve from SAP2000 model of Berths 306 and 307 can be seen in Figure C-4. For further information, please refer to the GDTM and Figure C-5 for a cross-section showing the embankment slip surface and pier structure.

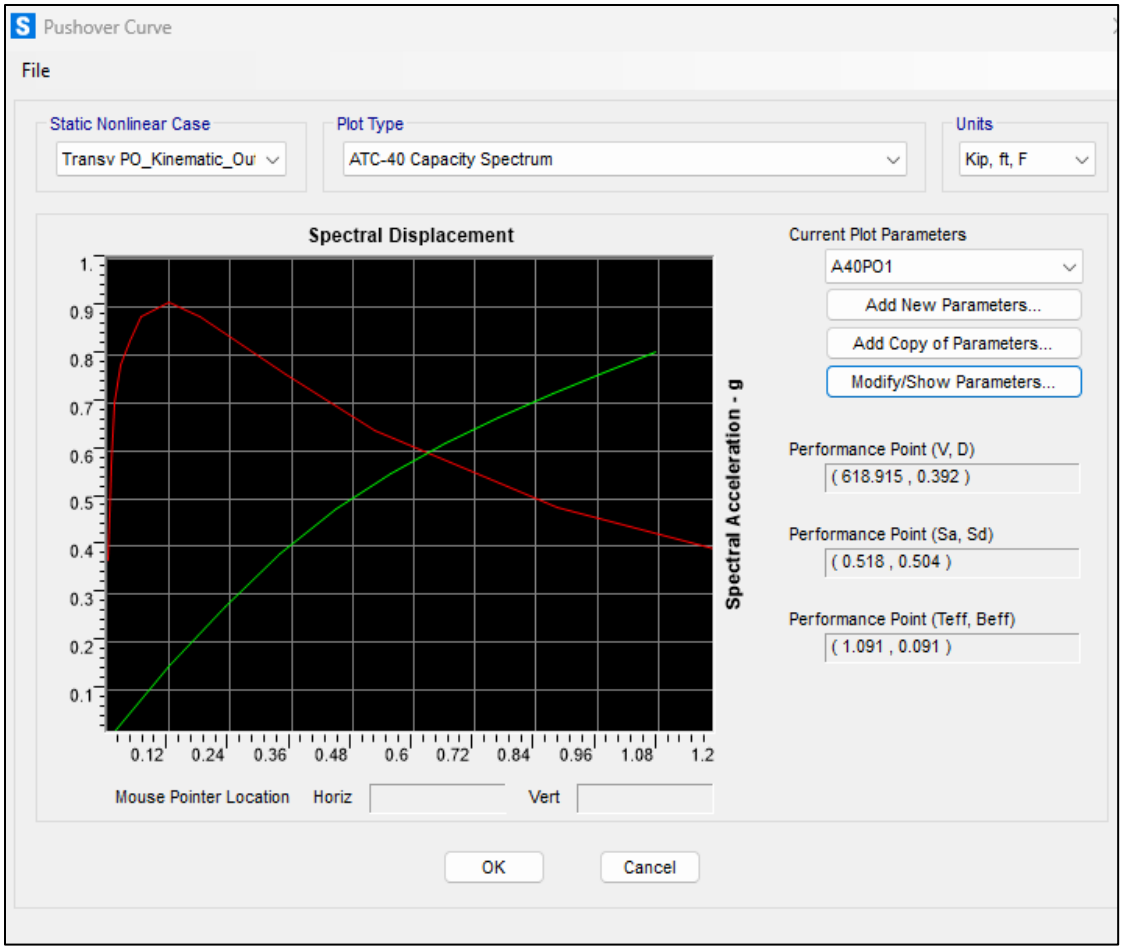

Figure C-4. Typical pushover curve from SAP2000 model of Berths 306 and 307

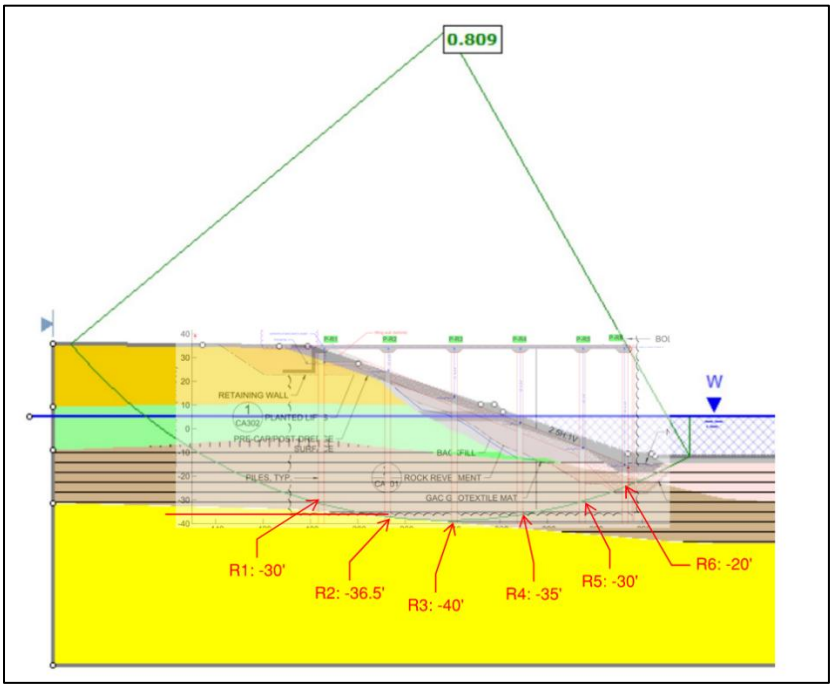

Figure C-5. Approximate modeled slip plane under Berths 306 and 307

Lateral ground deformations were modeled in SAP2000 as kinematic loads. Free-field slope displacements were applied to non-linear links above the elevation of the predicted slip surface determined by the Slide analysis. The analysis software calculates the kinematic load based on the relationship between slope displacement and pile displacement. Due to the narrow width of piers relative to the total length of the embankment, pile resistances do not significantly impact slope failure resistance or displacement reduction.

Further pushover analyses were completed for the post-lateral spreading event in accordance with ASCE 61-14. For the design, 100% of kinematic actions were combined with 100% of inertial actions. Design displacements in both orthogonal plan directions were combined in accordance with ASCE 61-14. Pile rotations, curvatures and strains were evaluated against codified limits for the DE and deck elements were designed to remain elastic in accordance with Section 3.1. Figure C-6 shows a screenshot of the analysis model in its final displaced state, highlighting plastic hinge locations.

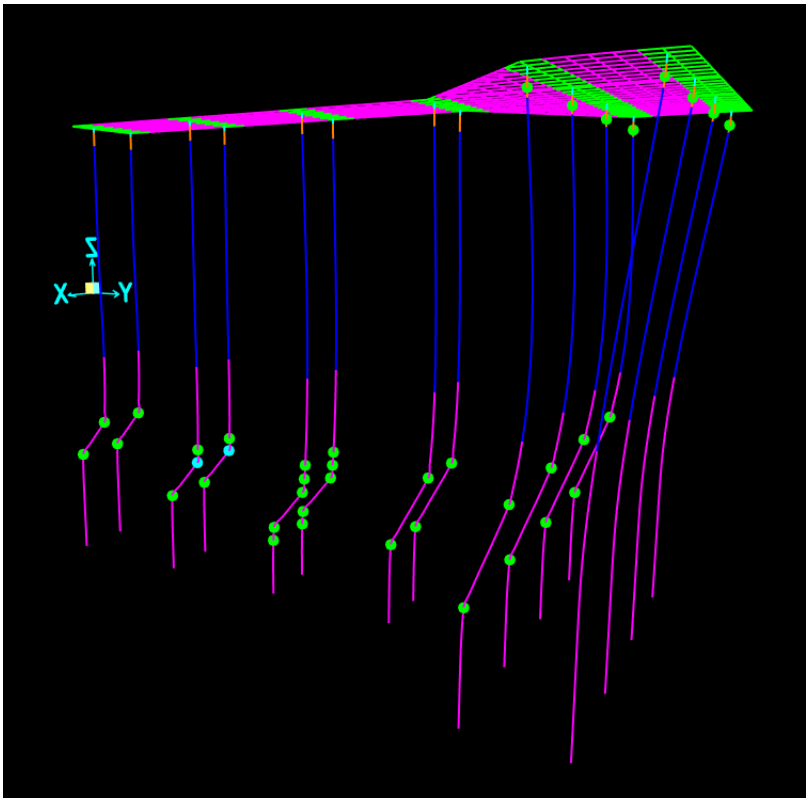

Figure C-6. Typical final displaced shape profile of pier highlighting pile hinge locations

The design of structural elements was in accordance with Section 3.0 utilizing the flexural and shear demands derived from the SAP2000 analysis.

7.4 BREASTING DOLPHINS

7.4.1 Structural Form

Replacement breasting dolphins are piled structures located at the toe of the new revetment slope to resist berthing and mooring actions of the design vessel. Each dolphin comprises six battered steel pipe piles approximately 2-ft in diameter battered at approximately 1:4 to resist lateral loads supporting a cast-in-place reinforced concrete pile cap approximately 5-ft thick. A vertical fendering system is constructed seaward of the pile cap consisting of a rubber cell fender and a pile supported fender panel located along the berth line. A single bollard with a safe working load of approximately 75 metric tons is located centrally on the pile cap. Two dolphins are furnished with access gangways to provide shore access for line handling.

7.4.2 Analysis and Design

A 3-D analysis model was created using SAP2000 (Figure C-7). The model represents all dolphins due to the similarity in subsurface soil conditions, geometry, and design loads. The pile cap is modeled using shell elements connected to concrete plug elements and steel pipe piles via rigid links from the mid-depth to the soffit of the pile cap. Pile plugs and steel pipe pile elements are modeled using line elements. Material and section properties adhere to Table C-1. The typical elevation at the top of the pile cap is approximately +36 ft. The revetment elevation at the seaward most pile location is approximately -15 ft.

Mooring loads were applied to the analysis model in accordance with Attachment A using concentrated loads applied at various horizontal and vertical angles. Berthing reactions were applied directly to the seaward side of the dolphin ignoring the resistance provided by vertical fender piles. Dead loads were included in the analysis model using the SAP2000 built-in self-weight function which calculates dead loads based on element geometry and material densities. Seismic effects were calculated to not be critical given the structures low seismic mass compared to factored berthing/mooring demands.

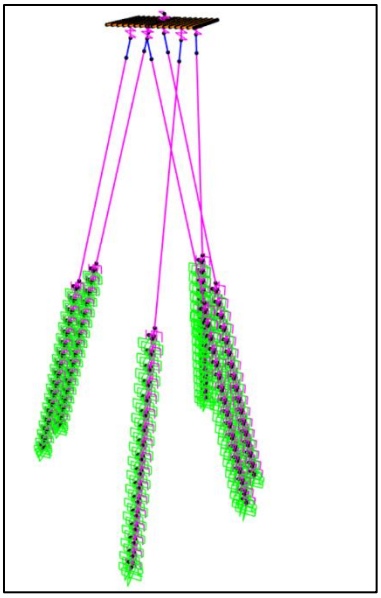

Figure C-7. SAP2000 model screenshot of typical dolphin at Berths 306 and 307

The design of structural elements was in accordance with Section 3.0 utilizing the flexural and shear demands derived from the SAP2000 analysis.

7.5 UP-SLOPE MOORING POINTS

7.5.1 Structural Form

Replacement up-slope mooring points are single-pile structures located at the crest of the revetment slope which resist mooring forces from the design vessel. Each mooring point comprises a 75 metric ton safe working load bollard anchored into steel pipe pile, approximately 3-ft in diameter driven into the upper slope with reinforced concrete infill over its upper extents.

7.5.2 Analysis and Design

A 3-D analysis model representative of all mooring points was created using SAP2000 (Figure C-8). Steel pile and pile infill elements are modeled using line elements. Rigid links were used to model the upstanding height of the bollard above the reinforced concrete infill at the top of the pile. Material and section properties adhere to Table C-1. The typical elevation at the top of the pile is approximately +36 ft, where the ground elevation is approximately +35 ft.

Mooring loads were applied to the analysis model in accordance with Attachment A using concentrated loads applied at various horizontal and vertical angles. Dead loads were included in the analysis model using the SAP2000 built-in self-weight function which calculates dead loads based on element geometry and material densities. By inspection, seismic loads do not control.

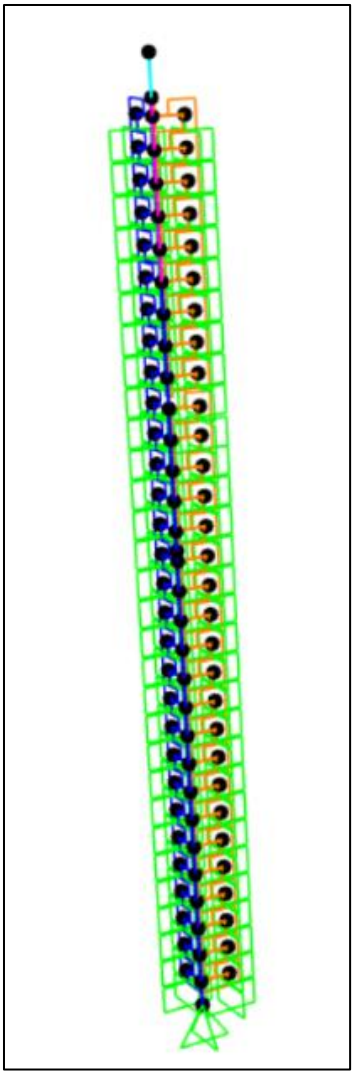

Figure C-8. SAP2000 model screenshot of typical landside mooring point near Berths 306 and 307

The design of structural elements was in accordance with Section 3.0 utilizing the flexural and shear demands derived from the SAP2000 analysis.

8.0 BERTH 311

8.1 EVALUATION OF OVERWATER STRUCTURE

- Geotechnical slope stability analysis was conducted for the under-structure and structure adjacent slopes, concluding that a maximum slope angle of 2.75H:1V is necessary to meet the design criteria for slope stability.
- Given the navigation requirement to provide a berth depth of approximately -20 ft in front of the berth, shoreline slopes of approx. 7H:1V beneath the berth apron and 3H:1V beneath the land spans are possible. These slopes meet geotechnical requirements.
- As-built grades beneath the land spans and the structure indicate an original slope angle of 3.0H:1V continuing to the berth pocket. Required slope geometry to achieve Remedial

Action Objectives and navigation depths include:

  - Maintaining a 3H:1V riprap armored slope beneath land spans and matching the as-built condition.
  - A 7H:1V slope beneath the berth, reducing elevated soil levels around piles which have occurred due to sedimentation over time.

- The current mooring infrastructure for Berth 311 includes using spud piles for vessels beyond the northwestern end of the berth. An existing mooring dolphin is understood to provide mooring restraint to these vessels but it does not provide adequate breasting restraint.
- A breasting dolphin has been designed to provide adequate breasting restraint to maintain operability of the berth.

8.2 FUNCTIONALLY EQUIVALENT MOORING INFRASTRUCTURE

Sufficient operational requirements were not available during the RD phase and will need to be obtained from and coordinated with SIDC to establish final breasting requirements. For planning purposes and the RD, a pile-supported breasting dolphin structure was designed using typical barge berthing loads to meet likely breasting requirements.

8.2.1 Structural Form

The new breasting dolphin evaluated for Pre-Final 90%RD includes a cast-in-place concrete pile cap supported on two vertical steel pipe piles driven into the underlying strata which resist a new steel pipe pile supported rubber fender system located along an extended berth line from Berth 311. The new dolphin is located north-west of the main berth, seaward of the existing mooring dolphin.

9.0 CITY OF PORTLAND STORMWATER OUTFALLS

9.1 EVALUATION OF STRUCTURES

- Five City of Portland stormwater outfalls—M1, M2, M3, S1, and S2—are impacted by the RA. The operational function of each outfall will be maintained.
- At each outfall location, embankment slopes will be excavated, regraded, and reconfigured to allow for the placement of capping layers, riprap revetment, and scour protection.
- Excavation at outfalls M1, M2, M3, and S2 will expose bell-end/spigot connections and regrading will require the removal of existing headwalls.
- Outfall S1 is located beneath the existing Lagoon Wharf structure, which will be removed and replaced.

9.2 FUNCTIONALLY EQUIVALENT REPLACEMENT STRUCTURES

Precast concrete pipe segments will be added as necessary to outfalls M1, M2, M3, and S2 to extend the existing outfall pipes, some up to 8 ft, to meet new slope grades and engineered cap

requirements. Precast concrete mitered headwalls, designed to align with the finished embankment slope profiles, will be installed.

The final design for outfall S1, which is located beneath the Lagoon Wharf structure will be incorporated into the design of the replacement structure.

10.0 LAGOON WHARF (BERTHS 302 - 305)

10.1 EVALUATION OF OVERWATER STRUCTURES

- The existing wharf is a timber wharf structure with a concrete deck. The structure is approximately 75 years old.
- The Design Criteria for the project require that riverbank slopes maintain a static factor of safety (FoS) greater than 1.5 and a seismic FoS greater than 1.0.
- Slope stability includes two components:
    - **Global Slope Stability** – related to the overall stability of a slope when considering the entire structure
    - **Local Slope Stability** – related to the stability of individual sections of a slope surface
- When looking at the global slope stability, the existing slope beneath the structure has a global static FoS near to 1.0, which is much less than the required FoS greater than 1.5. The existing global FoS has been validated multiple times in the past as well as through recent analysis performed by the RD team. In Figure C-9, the top cross-section is part of a 1981 geotechnical report, and the bottom cross-section is a similar evaluation performed by the RD team. The global slope failure or slip plane is indicated by the curved line beneath the structure and indicates that both the riverbank and the bottom of the basin in front of the structure.

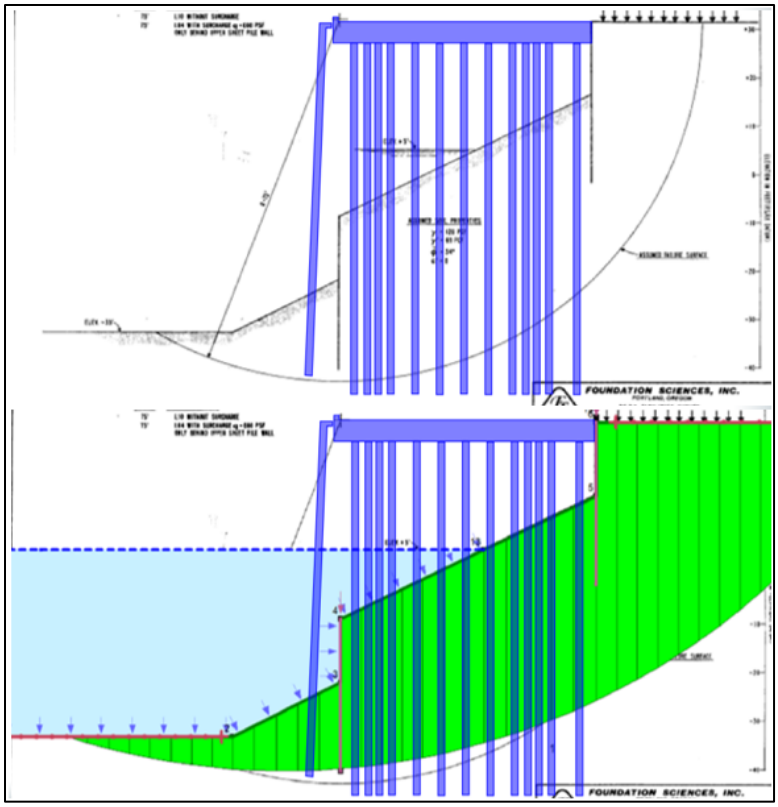

Figure C-9. Lagoon Wharf Global Slope Stability Checks

- The current structure—including the pier, bulkhead wall, and toe wall—does not satisfy the project's seismic design criteria and is anticipated to sustain damage during the defined seismic event. Furthermore, soil liquefaction and lateral movement toward the water are expected in such conditions, and the existing structure lacks sufficient capacity to withstand these forces.
- When looking at local slope stability, the ground surface below the existing structure is oversteep with a local static FoS near 1.0, which is much less than the required FoS greater than 1.5. Adding, removing, or replacing material will not create a stable slope that meets design criteria. This impacts the ability to implement a riverbank remedy that effectively reduces migration of contaminants of concern in riverbanks to sediment and surface water such that levels are acceptable for human health and ecological exposure (RAO 9).
- Several options were evaluated to achieve RAO 9 while keeping the existing structure. Although these alternatives improved local slope stability beneath the wharf, they did not address global slope stability to accepted standards. Additionally, installing new structural elements has the potential to damage the current wharf. Figures C-10 and C-11 show two of the alternatives considered.
    - Installation of a new toe wall with head restraint:

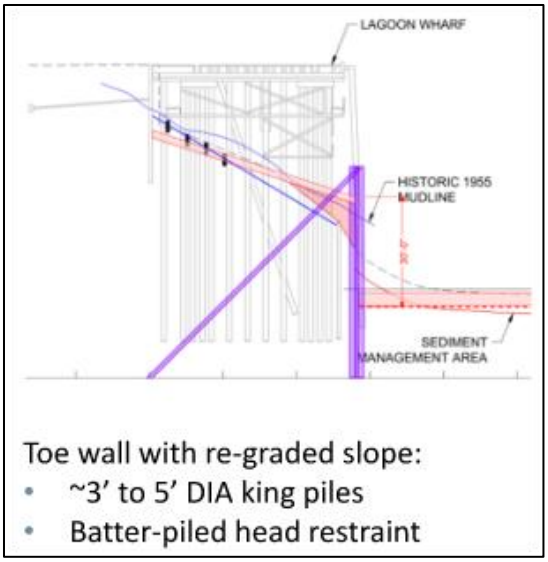

Figure C-10. New Toe Wall Alternative Considered

- Installation of a new toe wall with an anchored slope:

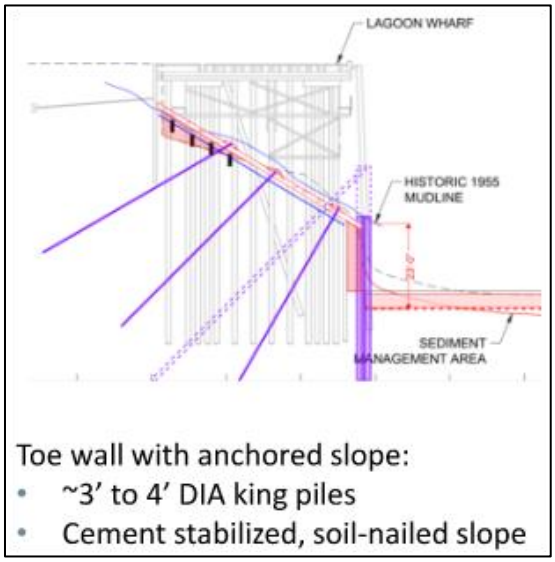

Figure C-11. New Pinned Slope Alternative Considered

- Conclusions:
  - The global stability of a reconfigured slope beneath the existing structure cannot be achieved with the existing structure in place.
  - The installation of new structural elements near the wharf has the potential to damage the existing timber structure. The construction of a large toe wall to allow for slope adjustments beneath the structure has the potential to affect the wharf's function and stability due to vibrations and existing pile down-drag caused by installation of the new elements. Working around older structures is often costly, labor-intensive, and presents additional safety risks.
  - Achievement of the RAOs is incompatible with protection of the existing structure.

- Replacement of the existing structure is the only feasible option to achieve RAOs under and around the Lagoon Wharf structure.

10.2 FUNCTIONALLY EQUIVALENT REPLACEMENT STRUCTURES

To achieve RAOs it was determined that the oversteep slope beneath the existing structure needs to be regraded or reinforced to avoid slope stability, liquefaction, and lateral spreading failures. Geotechnical analysis on the existing slope indicated that work beneath the current structure would be difficult to impossible without affecting slope stability. Given that achieving slope stability is not feasible with the existing structure in place, it was concluded that the current structure needs to be removed and replaced with a functionally equivalent structure to meet the RAOs of the project.

COST ANALYSIS TECHNICAL MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
SWAN ISLAND BASIN PROJECT AREA, CERCLA DOCKET NO. 10-2021-001
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

1.0 INTRODUCTION

This memorandum provides a cost estimate for the Pre-Final 90% Remedial Design (RD) within the Swan Island Basin (SIB) of the Portland Harbor Superfund Site (PHSS) in Portland, Multnomah County, Oregon. The HydroGeoLogic, Inc. (HGL) team performed the work on behalf of the SIB RD Group based on the requirements of the PHSS Record of Decision (ROD) (EPA, 2017) and the Administrative Settlement Agreement and Order on Consent (EPA, 2021). The data presented in this memorandum were collected in accordance with the final Pre-Design Investigation (PDI) Work Plan (HGL, 2022) and were reported in the PDI Evaluation Report (ER) (HGL, 2024a) and the Basis of Design Report (BODR) (HGL, 2024b).

This memorandum includes a Pre-Final 90% RD cost summary (Table 1-1) and documents the basis for line-item unit costs and quantities, including a discussion of methodology and approach. Attachment A includes tables that list line-item detail containing cost data (Table A-1), line-item notes and rationale (Table A-2), estimated annual budget expenditures (Tables A-3 and A-4), and assumptions applied to a probabilistic model performed on cost data to assess a range of project total cost within a 90% certainty (Table A-5).

This Cost Analysis was performed to meet Association for the Advancement of Cost Engineering (AACE) Class 1 estimating standards. The maturity level of project deliverables is estimated to be within 65-75%, which is near the lower end of a typical Class 1 estimation (65% to 100%). This is because of the ongoing development of structural elements and because of uncertainties related to key elements at the commencement of RA. The estimate retained the stochastic methodology, versus wholly deterministic, because of these considerations, and the expected accuracy range is estimated to be +10/-5%.

2.0 METHODOLOGY AND APPROACH

2.1 GENERAL COST ASSUMPTIONS

2.1.1 Project Scope Description

This memorandum presents the cost estimate to implement the Pre-Final 90% RD which, in summary, includes the following core work elements to complete the remediation:

- Selective dredge and/or cap of submerged sediments;
- Riverbank clearing and excavation to the project limits at the top of bank;

CORPORATE HEADQUARTERS
11107 Sunset Hills Road, Suite 400
Reston, Virginia 20190
703-478-5186

- Dredge water processing and treatment;
- Transport to a transload facility;
- Transload processing, upland transport to a disposal site, and disposal;
- Geotechnical stability of all riverbanks;
- Structure replacement and/or removal, where necessary to remediate localized sediments:
    - Lagoon Wharf (removal and new replacement),
    - Berth 306 (removal and new replacement),
    - Berth 307 (removal and new replacement),
    - Berth 308 (removal),
    - U.S. Coast Guard (toe wall, pile sleeves),
    - The Marine Consortium, Inc. Pier (mid-slope pinning walls),
    - Berth 311 (new breasting dolphin),
    - Shipyard Commerce Center Floating Dock Bulkhead Wall,
    - Port of Portland Dredge Base structural modifications;
- Native vegetation planting on riverbanks where slope stability can be retained to minimum of 3H:1V slope;
- Revetment construction on steep banks unable to support vegetation; and
- Soft costs (engineering, monitoring, administration).

2.1.2 Foundational Design Assumptions

The following are the design assumptions that establish the essential framework for the approach to the design and to the subsequential development the cost estimate.

A single process flow for disposal of contaminated material – The estimate assumes the following process flow.

1. All dredged and upland excavation materials are to be placed on a barge for transport to transload.
2. All riverbank excavation, fill, and planting will be performed from the water without upland access.
3. Free water from dredging operations is treated and discharged locally to the river such as with the use of Electrocoagulation or Chitosan Enhanced Sand Filtration. The methodology used during Remedial Action (RA) will be determined by the contractor. Specifics of this component are addressed in the Dredge Design Technical Memorandum (Volume I, Appendix H) and in the Specification Section 35 59 15 Temporary Contact Water Treatment (Volume III, Appendix U).
4. The remaining solids and porewater are transported by barge from the Project Area to a transload location in The Dalles upstream on the Columbia River (15 hours upstream and 8 hours return).

5. Following dewatering and stabilization during transload, the remaining solids are transported by truck to the Wasco County Landfill.

This singular process flow assumption is based on a viable set of activities that will meet design objectives. However, the following are key uncertainties that persist that can have an outsized effect on the total cost estimate.

1. Location of the transload and disposal sites at RA commencement:
    a. Both the use of The Dalles location as a transload site and Wasco County Landfill for disposal are considered viable options because they were used in disposal of contaminated dredge material from SIB in 2016. However, prior to commencement of the RA, the use of alternate locations may present cost-saving opportunities. Or, if the disposal facility must change because Wasco County can no longer accept material, costs could increase.
2. Upland access is currently unavailable:
    a. Communications with shoreline facility owners/operators to-date indicate that construction access for material delivery or staging is not available. Therefore, the design assumes all riverbank activity will be performed from the water (assuming a contractor work area elsewhere in Portland Harbor). However, future negotiations between shoreline owners/operators and the RA Contractor may result in agreements for upland access, notably for higher elevation riverbank activities that could achieve cost savings.

Remediation of sediment throughout SIB – The PDI ER (HGL, 2024a) reported exceedances of ROD contaminants of concern (COCs) in sediment and riverbank samples throughout the SIB Project Area. The PDI ER presents a more comprehensive and higher resolution characterization of the horizontal and vertical extent of COCs compared to the characterization published in the ROD (EPA, 2017). As reported in the BODR (HGL, 2024b), the sampling data indicates that riverbank subsurface soils throughout the SIB Project Area boundary exceed cleanup levels. Therefore, a combination of dredge/excavation and capping/soil cover was determined to be necessary to remediate submerged sediments and all riverbank soils.

Chemical isolation where dredge to remedial action level (RAL) infeasible – The removal of contaminated sediments/soils to concentrations below RALs was evaluated as a priority response. Where removal to RAL was infeasible because of excessive depth of material, different categories of caps were developed to chemically isolate subsurface contaminated sediment and the appropriate cap technologies were assigned based on spatially variable conditions. In the design plans (sheets CA102 to CA106), all areas identified as “Cap Type 1” and “Cap Type 2” are to be capped and areas identified as “Dredge to RAL” will be dredged to depths necessary to remove contaminate concentrations that exceed RALs.

Chemical isolation by capping is not proposed for areas where barge and ship spudding is required for continued operations. In these locations (identified in the design plans), capping technologies would be compromised by spudding, therefore, dredging to concentrations below RAL is the only most suitable option in these areas.

Compensatory Mitigation – The habitat impact evaluation was updated for the Pre-Final 90% RD and concluded that the overall impact and restoration to habitat conditions will be net negative. While the RD includes riverbank plantings with native vegetation to replace riprap and non-native vegetation, the extent of this habitat improvement on the riverbanks is insufficient to fully mitigate for the ecological impact anticipated by the RA. This means that compensatory mitigation will be required. An estimate for compensatory mitigation is included in the cost estimate obtained from mitigation credits available within the Alder Creek Restoration Project located on Sauvie Island. The habitat evaluation analysis completed for the Pre-Final 90% RD determined a habitat loss of -36.41 Discounted Service Acre Years (DSAYs). Mitigation credits from the Alder Creek Restoration Project are currently estimated at $62,000 per DSAY. Therefore, the mitigation cost is estimated at $2.26 million for habitat impacts. Details of the analysis and the considerations related to mitigation options are discussed in Habitat Impact Evaluation Technical Memorandum (Volume I, Appendix C).

2.2 COST CATEGORIES

Costs are grouped into three primary categories:

1. Bid costs – These are costs for tasks that a RA contractor will bid and bear responsibility for completion.
2. Additive bid costs – Unit costs for work not anticipated to be required but must be performed by the RA contractor if warranted.
3. RA Performing Party Costs – This category includes cost items that the RA Performing Party, and their designated representative, will assume responsibility and coordinate completion to provide essential oversight and monitoring. This category also includes actions that must be managed by the RA Performing Party to prevent avoidable interruptions in shoreline facility owner/operator operations.

2.3 ESTIMATED COSTS IN CURRENT DOLLARS

The costs included in this estimate are reported in current year (2025) dollars; escalation based on future value and inflation are not included. The total cost is intended to provide a platform to compare the line item elements of the total cost (and, subsequently, the design) and outline the apportionment of costs throughout RA period. As the remedial design advances into contracting development, a timeline can be determined from which cost escalation analysis can be reliably applied to the cost estimate.

2.4 SPECIFIC COST ITEM BACKGROUND AND RATIONALE

This section presents expanded rationale and background that provided the basis for the assignment of unit cost and quantities for selected line items. Table A-2 within Attachment A report the basis for items not specifically listed in this section. Additional tables include background and rationale related to unit prices, quantities, and to the probability distribution range applied to values modeled by Monte Carlo analysis.

2.4.1 Mobilization/Demobilization for Direct Construction Except Designated Structures

Mobilization costs are estimated as 10% of direct construction costs. The central work and output items that are part of mobilization costs include:

- Financial assurance and bonding;
- Development of closeout submittals and project record documents;
- Contractual overhead; and
- Work site establishment:
    - Operations facilities;
    - Fencing, lighting, security;
    - Stormwater management;
    - Pier/dock; and
    - On-site water treatment for daily decontamination during site operations related to sampling and measurement equipment.

The following categories of cost items are not included in the project-level mobilization:

- Structural implementations (mobilization is included in each of the structural costs);
- Procedural submittals;
- Remedial Action Work Plan;
- Standby times; and
- Additive and RA Performing Party Costs.

The estimated mobilization cost anticipates costs related to the establishment of upland work areas, the potential of a terminal for material import, piers or docks for ships and barges, and to potential adjustments likely to be needed to outfit a transload site to meet anticipated production rates.

A comparative basis for this proportional estimate is derived from the 2014 Passaic River project with similarly minimal access to adjacent upland areas. That project assigned 10% mobilization of construction costs to account for establishment of working areas both in the water and upland. The SIB Project Area lacks identifiable upland work area and it is anticipated that the RA Contractor will need to establish an upland area for operations, security, and possibly staging. The scope of mobilization tasks between the Passaic River project and SIB are similar and align with engineer judgement that 10% of construction costs is a reliable estimate.

Because the RA schedule predicts an annual work period of 4 months out of each year, additional mobilization costs are expected to allow for partial demobilization at the end of each construction season and then remobilization at the beginning of the next.

Mobilization costs are assumed to be apportioned among multiple construction years with more spent during the first year and less spent in subsequent years.

2.4.2 Procedural Costs and Agency Submittals

This work includes the development of RA Contractor submittals required for their Environmental Records Binder:

- Water Quality Protection Plan
- Temporary Erosion and Sediment Control Plan
- Stormwater Management Plan
- Spill Prevention, Control, and Countermeasure Plan
- Air Pollution, Noise, and Light Control Plan
- Traffic Control Plan
- Water Management Plan
- Health and Safety and Emergency Response Plans
- Green Remediation Plan

The cost for the submittals assumes 5 people x $150/hour x 8 hours x 6 months. The cost assumes additional time for stakeholder review for which uncertainty is considered high for the evolution and ultimate approval of each plan.

2.4.3 Utilities Protection and Restoration

Costs are included for performance of a specific survey of adjacent utilities infrastructure prior to the commencement of construction. Available design data to-date indicates that buried Lumen optical cable may be impacted by the RA; however, the full extent of utilities infrastructure is not fully known. The judgement of the design team is that the presence of utilities infrastructure not yet known is likely considering the extent of early development in SIB. However, such utilities are expected to require only protective measures because the project limits extend only to the top of bank throughout the basin. Therefore, it is likely that the cost for utilities protection and restoration may trend lower than the estimate. This probability was reflected in the cost model for this cost item.

2.4.4 Lagoon Wharf (New Structure)

The SIB RA cost estimate includes the cost for replacement of Lagoon Wharf (Berths 302-305). Replacement of the wharf is the largest cost item due to its size and configuration for use in large marine industrial activities. The requirement to replace the wharf is the result of two conclusions:

1) The COCs detected in riverbank soils throughout the length the wharf exceed RALs. Remedial Action Objective (RAO) 9 of the ROD requires reduction in concentration and exposure to COCs in the riverbank.
2) Geotechnical stability of the structure was determined to be insufficient to accommodate remedial methods such as capping without imposing a risk of failure to the structure.

The geotechnical analysis of the 75-year-old wharf structure assessed both the global slope stability (effecting the entire structure) and local slope stability (effecting individual sections). In assessing global stability, the structure does not satisfy design criteria for withstanding the defined seismic event and was assessed to have a Factor of Safety (FoS) of 1.0, lower than the required FoS 1.5. Underneath the structure, the ground surface is oversteep such that local static FoS is 1.0, also lower than the required FoS of 1.5.

Several alternatives were evaluated in place of structure removal; all options were insufficient in meeting structural design standards either because they were unable to achieve geotechnical stability requirements or that the installation had an unacceptable elevated risk of causing

catastrophic failure to the existing wharf structure. Therefore, to meet RAO 9 and remediate the high COC concentrations under and adjacent to this structure, the design team concluded that replacement is necessary. Further description of the analysis and conclusions are in Section 3.0 (Functionality Determination) of the Structure Design Technical Memorandum (DCR, Volume I, Appendix J); and details of the stability evaluation and alternatives assessment are discussed in the Section 10.1 (Evaluation of Overwater Structures) in Attachment C of the Structure Design Technical Memorandum (Volume I, Appendix J).

The design for the replacement of the wharf has been advanced to a conceptual stage by the structural design firm, KPFF Consulting Engineers (KPFF). Details and background are included in the design study (KPFF, 2025). The conceptual design analysis in the study identified two potential alternatives: 1) a bulkhead option, and 2) a pile-supported option. The study concluded that the bulkhead option meets design goals, would require approximately 65% of the pile-supported construction duration and cost 25% less. To evaluate a total cost for the SIB Project Area RA, the cost of the bulkhead option was used as the likely cost for replacement of the wharf.

Other technical considerations may surface as the replacement wharf design progresses that could require a re-evaluation of the alternatives such as the pile-supported option. To accommodate the possibility, the cost of the wharf is included in the cost model and assigned a “maximum extreme” distribution with a maximum value equal to 150% of the likely cost of the bulkhead option ($396M). This upper value exceeds the likely estimate for the pile-supported option ($346M). Configured for the lagoon wharf total cost, this distribution assignment establishes a probability curve (Figure 2-3) that assigns costs between $240M and $300M a greater than 50% probability. And the probability of costs more than $300M exponentially lower to the maximum possible value ($346M).

2.4.5 Outfall Rebuilds

The quantity of outfall rebuilds (small and large) includes only those outfalls that do not outlet under the Lagoon Wharf. Costs for all outfalls currently under the wharf are to be included in the design for the wharf by the third-party design team.

2.4.6 Structural Engineering Design Plan Submittals

The submittals developed for structural designs are separate from the procedural and agency plans and submittals. This separation anticipates that separate contractors are likely to complete these different sets of reports.

2.4.7 Material T2C: (Sand with 5 percent Granular Activated Carbon)

Material T2C is a sand and 5% granular activated carbon (GAC) blended mix. The “T2C” is a RD designator used to differentiate the collection of the project material imports. The following table outlines the calculations used to estimate the unit cost (per cubic yard [CY]). Because the source for GAC can have a significant effect on the final unit cost of the sand/GAC mix, the distribution variability was assigned a range of 80-140% of the cost estimate.

Cost Category	Cost	Unit	Notes
GAC (escalated):	$1.79 $3,587.44	lb ton	From EPA GAC planning worksheet (2023) for high volume purchases (>40 tons) and escalated to 2025 dollars using CWCCIS "Beach Replenishment" category.
GAC cost per ton of sand/GAC mix:	$179.37	ton	5% GAC
Sand	$80.00 $53.33	CY ton	Sand procurement cost based on 1/2 of Vigor cost of "fish mix"
Estimated Sand/GAC blend surcharge:	+0.15	%	
Total Sand/GAC mix cost (+blend)	$267.61	ton	Combined sand and GAC cost times blend surcharge
Sand/GAC mix mass/volume conversion:			
GAC density	0.5	g/cm3	Mean bulk density from typical range of 0.4 to 0.6 g/cm3
GAC	0.4215	ton/cy	Conversion using 0.843 tn/cy per g/cm3
Sand weight/volume conversion	1.5	ton/cy	
Sand/GAC(5%) mix weight/volume conversion	1.446	ton/cy	
Total Sand/GAC mix cost by volume:	**$386.99**	CY	Combined sand and GAC cost (+blend surcharge), using weight/vol conversion for sand/GAC mix

Notes:
% = percent
CY = cubic yard
GAC = granular activated carbon
lb = pound

2.4.8 Dredge/Excavation, Transload, Upland Transport, and Disposal

2.4.8.1 Description

The dredging/excavation and ultimate disposal of materials within SIB is performed by a collection of successive tasks. The bid items addressed by this section (except for the treatment of water from dredging operations which is discussed separately) include:

Cost ID	Cost Item Description
01.25.01	Required Dredging and In-Water Transportation (Open-Water) - Clamshell
01.25.02	Required Dredging and In-Water Transportation (Nearshore, below El 8 ft NAVD88) - Clamshell
01.25.03	Required Dredging and In-Water Transportation (Restricted Access) - Clamshell/Excavator
01.25.04	Free Water Decant/Treatment/Discharge from Dredging Operations
01.25.05	Riverbank excavation (above El 8ft NAVD88) and in-water transport.
01.25.09	Dredged/Excavated Material Transload
01.25.10	Dredged/Excavated Material Upland Transportation, and Disposal (Subtitle D)

Notes:
NAVD88 = North American Vertical Datum of 1988

These cost items address a collection of successive activities that are selectively grouped into cost items. The joining of tasks into singular bid items addresses two related conditions: 1) the cost source includes similar grouping (the same tasks were bid as a single item), and 2) an anticipation that bundled tasks could be performed by separate contractors. The following table includes a description of the activities and the Cost IDs that include each activity. A Cost ID is repeated when

that cost item includes multiple activities. For example, Cost ID 01.25.01 includes 1) dredging, 4) transport to transload, and 5) stabilization of material.

Activity Description (in sequence)	Associated Cost ID
1. Dredging of sediment in submerged and submersible areas	01.25.01 01.25.02 01.25.03
2. Excavation of upland areas	01.25.05
3. Treatment of dredge return water and subsequent discharge locally;	01.25.04
4. Transportation of material (following removal/treatment of free water) by barge to a transload facility located at The Dalles on the Columbia River;	01.25.01 01.25.02 01.25.03 01.25.05
5. Stabilization of material in-transit;	01.25.01 01.25.02 01.25.03 01.25.05
6. At the transload facility, relocate material from barge to trucks;	01.25.09
7. Upland transport from transload to disposal facility;	01.25.10
8. Dewatering treatment and solids disposal in EPA-approved facility.	01.25.10

2.4.8.2 Unit Cost Basis

A dredge project was completed for Vigor's Dry Dock 6 in 2015 in which the sequence of activities was analogous to those expected to be performed in SIB. The sediment removal included dredging, in-water transport to The Dalles transload location, transload, and upland transport to Waste Connections disposal facility for wastewater processing and disposal. The cost estimate for the SIB project assumes a similar sequence of activities including the use of The Dalles for transload and Waste Connection for disposal.

The contractor for the 2015 dredging project developed cost estimates prior to construction. Assuming similar activities, that dredging is to be performed on the same site and that the disposal pathway was the same, the 2015 costs were used as the basis for SIB costs, following escalation to 2025 dollars using the U. S. Army Corps of Engineers (USACE) Civil Works Construction Cost Index System (CWCCIS) Cost Escalation.

Open-water, nearshore, and restricted dredging production rates – The 2015 cost for open-water dredging was adopted directly for open-water dredging and escalated as the unit cost for open-water dredging in SIB. The table below outlines the sequential calculation for open-water dredging and in-water transport to the transload facility:

Cost basis for open-water dredge and transport		
2015 Dry Dock 6 dredge and transport cost:	$17.60	$/ton
CWCCIS escalation factor (2015 to 2025):	1.459	
Open-water dredge/transport cost 2025 dollars (* escalation):	$25.67	ton
Sediment density	1.5	ton/CY
Open-water dredge/transport cost, per CY, 2025 dollars (* sediment density)	**$38.51**	$/CY

Nearshore dredging refers to the removal of material in shallow waters. Nearshore dredging differs from open-water dredging in that different equipment and methods are anticipated. A key characteristic of nearshore dredging is that the draft of the equipment barge will limit operation within shallow waters and require equipment with an extended reach. Therefore, the production rate of nearshore dredging is estimated to be lower compared with open-water. The table below outlines the basis of cost for nearshore dredging.

Cost calculation for nearshore dredging and transport		
Open-water dredge/transport cost, per cy, 2025 dollars	$38.51	$/cy
Estimated open-water production rate	1,150	cy/day
Estimated nearshore production rate	300	cy/day
Nearshore production rate ratio (nearshore/open-water)	0.26	
Nearshore dredge/transport cost, per cy, 2025 dollars (open-water dredge/nearshore rate ratio)	**$147.62**	$/cy

Restricted dredging is nearshore dredging performed near protected infrastructure such as pilings. The equipment needed to complete this type of dredging is anticipated to be similar; however, the production rate is expected to be lower than nearshore to account for access challenges. The table below outlines the basis of cost for restricted dredging.

Cost calculation for restricted dredging and transport		
Open-water dredge/transport cost, per cy, 2025 dollars	$38.51	$/cy
Estimated open-water production rate	1,150	cy/day
Estimated restricted production rate	250	cy/day
Restricted production rate ratio (nearshore/open-water)	0.22	
Restricted dredge/transport cost, per cy, 2025 dollars (open-water dredge/restricted rate ratio)	**$177.14**	$/cy

See Table 4-1 in the Dredge Design Technical Memorandum (Volume I, Appendix H) for the basis of the estimated production rates.

2.4.9 Dredge Return Water Treatment and Discharge

This activity refers to the treatment of excess water collected during dredging operations. The cost assumes a localized system that treats dredge return water either on an in-water barge or within a landside facility and can discharge effluent directly into the Willamette River. The treatment effluent must be monitored and meet applicable State and EPA requirements for water quality parameters.

The 2015 Dry Dock 6 dredging project also required dredge return water treatment; however, excess water was pumped upland to Vigor's wastewater treatment system. Therefore, water treatment was not a component of that project's cost. The use of Vigor's wastewater system or other upland wastewater systems were concluded to not be viable for SIB dredging because 1) dredging operations are required throughout the basin, limiting access to upland inlet locations, 2) pump line infrastructure would impede marine operations, and 3) that dredge water volumes would likely exceed any of the wastewater system capacities.

The cost and method of water treatment is based on pilot systems implemented for Early Action Areas in 2013 within the Lower Duwamish Waterway. Two sites were established to implement Electrocoagulation (EC) treatment and Chitosan Enhance Sand Filtration (CESF). Like conditions at SIB, traditional dewatering systems were not viable in the Lower Duwamish River because of the presence of heavy metals and polychlorinated biphynels. Both systems achieved target water processing volume rates and produced effluent that exceeded water quality levels allowing local discharge. The details and cost from these implementations were obtained from a dredging study by L.M. Doty (Doty, L. 2015). Specifics and requirements for the implementation of a similar system for SIB are included in Specification Section 35 59 15 (Volume III Appendix V).

The reported average cost of 10M gallons from both sites was $.0395/gallon. This cost was escalated to 2025 dollars and is the basis of cost for in-water dredge return water treatment ($0.0563/gallon). Because of the uncertainty of implementing a similar system based on a 12-year old pilot implementation, the probability distribution in the cost model varied the unit cost from 85% to 170% of the estimate.

2.4.10 Environmental Compliance Monitoring (Water Quality Monitoring, Air Pollution/Noise/Light)

The following outlines the sub-elements that contribute to monthly cost estimate for this task element.

Turbidity monitoring	It is assumed these are done by multi-parameter sondes provided with the sampling vessel, 1 per vessel, plus labor costs including the sondes. For background turbidity, hardness, DO and pH two sondes at $2,000 each is estimated for duration of the project.
Analytical Costs	For COCs, 1 sample per day x 6 days per week of dredging x 4 weeks per month =24 samplings per month x 14 Samples for analyses = 336 samples for analysis. Samples are analyzed for 14 analytical sample groups. Analytical costs for these Total and Dissolved sample groups are $348,000 per month based on Monterey Labs Fee Schedule for 2025.
Sample Processing	336 analytical samples /3 per hour x $130 per hour= $14,560 per month
Sample Shipping	336 samples/4 per cooler=84 coolers x $100 per cooler=$8,400 per month.
Quality of Life Monitoring	Quality of Life monitoring is done at the dredge (Air Pollution, Noise, Odors) -estimate is $5,000 per month per dredge (labor, sampling, analysis). From Passaic River 2014 Remediation Estimate.

2.4.11 Long-Term Monitoring

The activities performed for long-term monitoring within the SIB Project Area are detailed in the Project Area Monitoring Plan (Volume II, Appendix P). This cost includes monitoring activities specific to periodic porewater and sediment sampling, sediment profile imaging, and physical observations. The monitoring program is composed of two main components: (1) a baseline dataset of post-RA conditions and (2) periodic performance sampling, sediment profile imaging, and physical observations.

Porewater sampling will include multi-depth passive sampling to collect a minimum of two intervals at each sampling port opening – one within chemical isolation layer (CIL), and one above CIL. This cost estimate includes three intervals to account for additional sampling needs.

Sediment cores will be collected from both the armor layer and deposited sediment above CIL, if available, with each core analyzed at a minimum of two depth intervals (above and below the bioturbation layer). The cost estimate includes three depth intervals per core to account for additional sampling needs.

The monitoring schedule includes three initial post-RA periodic sampling events: once within the first year and two between years 1 through 4 post-construction. After year 5, sampling events will occur once every five years for 95 years.

Table 2-1 outlines the specific calculations and subitem costs used to calculate the lump sum cost for long-term monitoring.

2.4.12 Toxicity Characteristic Leaching Procedure Metals Analysis for Waste Characterization

This is a component of pre-dredging landfill and regulatory acceptance of the sediment for disposal and will occur during the RA planning stage before dredging commences. The estimated number of samples meets standard landfill sampling frequency for waste designation and disposal. Cost components are as follows:

- Toxicity Characteristic Leaching Procedure (TCLP) metals analyses: $8,400 ($280 per sample, 30 samples)
- Vessel costs: $56,000 ($7,000 per day, 8 days)
- Field staff (3): $52,600 ($200 per hour, 10-12 hours per day, 8 days)
- Supplies/Equipment: $2,000 (rough estimate, includes miscellaneous expenses)
- Field preparation: $3,000 (creating/printing labels, field sheets, sample map, preparing supplies, preparatory meetings, etc.)
- Travel-related expenses: $6,000 (rough estimate, 3x per diem for 9 days, travel reimbursement)

2.4.13 Sampling Ports

The procurement and assembly of the sampling ports for cap monitoring is based on costs related to concrete septic tank with sizes similar to port structures in open water and those intended for revetment areas. The ¾ inch steel plates were priced at $76 per square foot (ft).

- Large sampling port: $2,000 for concrete and $1,254 for steel plate = $3,254 per port
- Smaller sampling port: $480 for the concrete and $456 for the steel plate = $938 per port

The installation of the sampling ports was based on costs to install boat moorings: $8,000 (labor and vessel with barge and crane) to install a maximum of 10 ports per day.

2.4.14 Temporary Relocation of Floating Structures

The temporary relocation costs (items 10.10.02-11) were based on the following work elements:

- Floating boom relocation
- Floating dock relocation
- Dry dock relocation

Each floating structure can require a combination of these items.

The cost centers on crew size and judgement of time required for the different work elements. Production was assigned and limited to full work shifts or half shifts for the smaller work locations. All relocations are assumed to occur within the basin and during the phased construction.

Item cost also includes specific estimated contingency, indirect costs, contractor markup.

2.4.15 Unexploded Ordinance Disposal (Additive)

The disposal of unexploded ordnance (UXO) is included as an additive line item because of the military industrial history of the SIB Project Area. Data available about debris is not sufficient to definitely exclude UXO; therefore, it is included as an additive bid item with a quantity of one (1).

The cost is estimated at $18,500 per demolition event, the minimum required for any single ordinance item (considered either Munitions and Explosives of Concern [MEC] or Material Potentially Possessing an Explosive Hazard [MPPEH]). Each event will require a minimum of 3 people (1 Senior UXO Supervisor, 1 UXO Safety Officer, and 1 UXO Technician II) who would mobilize for a single day. Each demolition event includes 16 hours of mobilization/demobilization travel, and 10 hours of time for demolition operations. If multiple UXOs are found, the cost is likely to reduce if items discovered are safe to move as part of a single event.

2.4.16 Oregon Department of State Lands Division 145 Cost Estimation

Oregon Administrative Rules Chapter 141 Division 145 governs the management of state-owned submerged and submersible lands subject to remediation and habitat restoration activities. EPA established their position with respect to potential Division 145 costs in the ROD (EPA, 2017) in response to comments from Oregon Department of Environmental Quality (DEQ):

"*Department of State Lands propriety authorizations, which include lease fees, were not included in the cost estimates. EPA acknowledges that the State Land Board through the Department of State Lands promulgated rules for granting and renewal of access authorizations, leases, and easements issued to facilitate remediation conducted pursuant to an order issued by DEQ or EPA and habitat restoration activities in, on, under or over state-owned submerged and submersible land. However, Section 104 of CERCLA, 42 U.S.C. § 9604 provides the President with broad authority to take response actions determined necessary to protect the public welfare and the environment from releases or the potential threat of a release of hazardous substances or pollutants and contaminants to the environment presenting an imminent and substantial endangerment to public health and welfare.*"

"If EPA were to perform the remedy, the United States would not be required to pay state fees. However, EPA expects most, if not all, of the remedy (cleanup actions) will be performed by PRPs and EPA anticipates that PRPs will negotiate reasonable terms and conditions of access to private and state-owned property to implement the remedy likely with landowners and Department of State Lands."

The cost analysis for the Pre-Final 90% RD includes a line item for potential Division 145 costs. As part of coordination, the Oregon Department of State Lands (DSL) provided its draft "Portland Harbor Superfund Site Oregon DSL Division 145 Remedial Design Cost Estimator" spreadsheet calculator to SIB RD team for use in the cost analysis. The calculator worksheet and parameter definitions are included in Attachment E. The calculator produces an estimated easement cost based on the anticipated temporary and long-term impacts of the remedy on public trust uses and management of state submerged or submersible lands, using inputs selected by the user. The SIB RD Team utilized the calculator to estimate Division 145 costs for the RA anticipated in the SIB Project Area, incorporating the following information that was derived from the Pre-Final 90% RD:

- Area inaccessible or only partially accessible during the active construction period
- Length of the active construction period
- Areas of buried contamination, cap, and/or other permanent in-water structures constructed as part of the remedy
- Additional areas of institutional controls

The calculator also considers the assessed value of upland properties adjacent to the state submerged or submersible lands within the SIB Project Area.

The Pre-Final 90% RD includes a total area of 79.09 acres of cap and/or other permanent structures constructed as part of the remedy. The resulting estimated cost for two consecutive 30-year easements for these aspects of the remedy is $39.3 million; with costs associated with construction estimated around $1 million and post-construction costs around $38 million. This estimated cost, included herein, was derived using the August 2025 draft calculator developed by Oregon DSL. Uncertainty around this line item is characterized by using a triangle distribution with a low value of 0.8 and a high value of 1.2 times the estimated cost. The SIB RD Team anticipates that the actual cost will be negotiated between the RA Performing Parties and Oregon DSL.

2.5 TOTAL PROJECT COST VARIABILITY

The total project cost estimate for the SIB Project Area includes potential lower and upper costs establishing a probable range produced from a probabilistic model employing a Monte Carlo simulation. The lower and upper possible costs fall within a 90% confidence level predicted by the results of the simulation. This approach to estimating costs related to inherent uncertainty was preferred instead of the deterministic method that addresses uncertainty with a single fixed contingency typically estimated as a percentage of the project total cost. The use of the model allowed varying uncertainties in specific cost item values to be represented individually and to highlight variability in unit costs and quantities that have a more significant impact on the total project cost.

The summary of project costs presented in Table 1-1 includes the potential lower and upper limits of possible project cost within a 90% certainty calculated in the Monte Carlo simulation. This total cost range is also depicted graphically in Figure 2-1.

2.5.1 Addressing Uncertainties with Probabilistic Modeling

To account for uncertainty of costs, the probabilistic model was employed to capture the uncertainty in each item and represent the relative effect of each item on the total cost. Microsoft Excel-based Crystal Ball software, developed by Oracle®, was selected to perform the probabilistic modeling. Crystal Ball is designed to model uncertainty based on variability within the input variables during randomized trials using the Monte Carlo method.

The model simulation performed 10,000 trials wherein a range of values are randomly generated for probability assumptions assigned to each unit cost and quantity value having an inherent uncertainty. At model completion, the total cost is forecasted using the full range of possible outcomes from the contribution of individual cost items and their relative uncertainty.

The uncertainty in unit costs and quantities is represented as a range of potential values from a probable minimum value to a probable maximum value. The range in values is typically assigned using a factor applied to the estimated cost or quantity. The factors used to calculate possible minimum and maximum values in the model are listed in Table A-4 within Attachment A. A larger variability (relative to the initial value) reflects a higher uncertainty while a narrow range would imply more certainty in the value.

Values in the cost model were assigned the following probability distributions:

1. ***Triangle probability distribution*** – The triangle distribution is the most common assumption for value variability. The probability of a value selected during the cost simulation increases linearly from both the possible minimum and maximum values, where the probability at these extents are near zero, to the likely value, a near 100% probability. The minimum and maximum values are set from assigned factors of the initial value estimate (for example, a factor of 1.2 will establish a model value maximum that is 120% of the initial estimate value). The following outlines the range of possible values used to assign the lower and upper values in the triangle distribution (the factor is multiplied with the line item unit cost).
    - Unit costs from 5+ year sources: -20% – +50%.
        - Unit costs derived from Vigor, Lower Passaic, Stratford (discussed in Section2.6) align well with the line items; however, they are 10-year-old costs; therefore the maximum factor variability is expected to be high.
    - Typical unit costs: -15% – +30%.
        - A review of Oregon Department of Transportation bid data shows costs show a variability of 30% around an average. It is applied to most unit cost values. The variability leans upward (the low value factor being 0.85) considering the costs are in 2025 dollars for estimated construction start 8-10 years in the future.

- Low certainty values: -30% – +50%.
    - For values (unit costs or quantities) from which an applicable background is insufficient to provide a higher confidence estimate value.
- Custom variability
    - Values may be assigned a custom variability range to reflect judgement about inherent uncertainty specific to that item (and value) and documented in the unit cost or quantity rationale.

2. ***Gamma distribution*** – The gamma distribution was assigned to the following structure costs:

    - Berth 306 (new structure)
    - Berth 307 (new structure)
    - U.S. Coast Guard (toe wall, pile sleeves)
    - The Marine Consortium, Inc. Pier (mid-slope pinning walls)
    - Berth 311 (seismic restraint)
    - Port of Portland Dredge Base structural modifications

    The gamma distribution (illustrated in an example chart shown in Figure 2-2) is a continuous probability distribution with a probability density function with shape and scale parameters that allow for flexible skewing of values. Using a scale of 20 and 4% of the maximum/minimum cost difference, this distribution skews the probability that the structure cost is at, or above, the initial estimated cost.

    The estimated structure cost contains contractor direct costs and anticipated known, and design, contingencies. The possible maximum cost accounts for an estimation of unknown contingency. The gamma distribution was selected because it more appropriately represents the higher probability of a structure cost to include a partial, or all, of the unknown contingency and that a structure cost not requiring any unknown contingency is much less probable.

3. ***Maximum extreme distribution*** – This distribution was assigned only to the Lagoon Wharf. The maximum extreme probability distribution is commonly used for breaking strengths of materials, loads and tolerances. This distribution favors values in the upper range, but the probability of extreme values drops exponentially. Applied to the conceptual-level costs for the Lagoon Wharf, a higher probability is assigned to costs exceeding the likely cost. This probability assignment configuration captures the possibility that the wharf replacement could require a higher cost alternative such as the pile-supported option. However, this distribution also assigns a rapidly lower probability that the more expensive option will be required.

    Encompassed within the probabilistic cost range is that the likely cost estimate additionally includes contingency, meaning that the probabilistic assumption varies the cost, with contingency. In the model, the contingency is assumed to be generic, and that the probability is elevated that the structure cost will require most of the stated contingency. However, assigned the maximum extreme distribution, the probability that unknown costs will be required will exponentially lower at the more extreme cost values.

All remaining values that are known to not deviate are assigned a static value that is unchanged in the model. This would include, for example, values of '1' for lump sum items or for quantities that are calculated and are wholly dependent on other values.

2.6 SOURCES OF UNIT COSTS

The following lists the sources used as a basis for the unit costs included in the SIB Project Area cost estimate. The source abbreviation appears in the column "Unit Cost Source" in the cost estimate workbook (Attachment A).

Source Abbreviation	Source Year	Source Description
Terminal 1	2024	Bids for Port of Vancouver Terminal 1 bulkhead project. Key related items included pile removal, slope excavation, and material acquisition.
Vigor Dredge	2016	Vigor dry dock dredge project. The Vigor dredge project established the viability of dredge material transport, transload (to the Dalles), and disposal.
Passaic	2014	Lower Eight Miles of the Lower Passaic River Study Area of the Diamond Alkali Superfund Site The Passaic River project was a similar large-volume project exceeding SIB volumes wherein Passaic required dredging 10 million CY of sediment and placement of 1.8 million cubic yards of capping. Costs obtained from this project were evaluated as part of a Focused Feasibility Study (FFS) of dredging and capping, including long term monitoring and operation and maintenance. The FFS estimate was done by Louis Berger Engineers in 2014.
Stratford	2018	Stratford Army Engine Plant Superfund This site is a former aircraft manufacturing facility. After closure the facility was investigated and found to contain shoreline sediments contaminated with polychlorinated biphenyls, metals and polycyclic aromatic hydrocarbons. The Connecticut Department of Energy and Environmental Protection has required cleanup of over 170,000 cy of sediment and placement of over 111,000 cy of clean backfill. J. Lally Associates performed a Focused Feasibility Study (FFS) and cost estimate evaluating remedial alternatives for the sediment cleanup from which costs related to SIB were derived. The Stratford FFS was done in 2018 for the USACE New England District who is responsible for the cleanup.
LDW	2023	100% Final Design Report, Appendix O, Lower Duwamish Waterway (LDW) Group.
Doty	2015	Electrocoagulation and Chitosan Enhanced Sand Filtration treatment study in LDW. This study by L.M. Doty included pilot implementations of in-barge free water treatment methods that could be adopted for SIB Project Area.
Monterey	2025	Monterey Labs Fee Schedule for sample analysis
Vendor	2025	Vendor quote specific to the product item listed.
Alder Creek	2025	Alder Creek Mitigation Bank Alder Creek is the source for mitigation cost to address habitat impacts and is based on communication with Wildlands that included cost estimates for to purchase DSAY mitigation credits.
ODOT	2024	Oregon State Department of Transportation (ODOT) bid item database
WSDOT	2024	Washington State Department of Transportation (WSDOT) bid item database

Source Abbreviation	Source Year	Source Description
EPJ	2025	Engineer professional judgement.
PH RI/FS	2016	Portland Harbor (PH) Remedial Investigation/Feasibility Study (RI/FS), Appendix G – Update, Detailed Analysis Cost Estimate, November 16, 2016, EPA Team; Present Value Analysis and Detailed Cost Estimate Summary, Alternative F Modified; Table CS-F (MOD) Detailed Cost Estimate Summary, pp 19-22 (alt. sub-memo pp 2-5)

2.6.1 Escalation of Earlier Cost Sources

Unit costs derived from earlier sources were escalated to current 2025 dollars in the State of Oregon using the U.S. Army Corps of Engineers Civil Works Construction Cost Index System (CWCCIS), with index tables updated September 2024.

A key element of using the CWCCIS is the selection of the Civil Works Breakdown Structure (CWWBS) feature codes. The 20 codes included in the CWCCIS are broad categories requiring interpretation of the codes that are applicable to a particular SIB Project Area cost item. The following feature codes were the basis of most cost escalations:

CWWBS Feature Codes	Unit Cost Item Applications
18 - Cultural Resource Preservation	Administrative, community coordination, easements
20 - Channels and Canals	Dredging, excavation, and debris removal activities
20 - Permanent Operating Equipment	Transload, Transport, Disposal

2.7 GUIDANCE

The cost analysis was completed following guidance outlined in *Appendix G - Methodology and Organization of Selected Remedy Cost Estimate* (EPA, 2016) and in *A Guide to Developing and Documenting Cost Estimates During the Feasibility Study* (EPA, 2000). Initial cost data was referenced in *Appendix IV Updated FS Information and Supplemental Information for Alternative F Modified* (EPA, 2017).

3.0 RISK REGISTER

Attachment D includes a register of potential project risks that have a low probability of occurring but could have a substantive effect on the total project cost. The attached register documents the conditions under which each risk element would occur, the potential range of cost impact, and mitigation measures to minimize the potential for the risk to be realized.

While the register of risks could be feasibly included in the probabilistic cost model, the conditions that would trigger the risk items are improbable and the scope of possible cost effect is too varied to assign a meaningful probability distribution in a similar way compared to the probabilities assigned to other cost element values. Therefore, the risk items listed on the register of risks were not included in the probabilistic model but instead listed as remote, but possible, risks to the project. The utility of the register of risks therefore focuses on establishing awareness and motivating mitigation of low-probability risks that could affect the RA cost.

4.0 COST ASSUMPTIONS

The cost estimate assumes the following:

No tax – Tax is not included in any costs. This is concluded to be a reasonable assumption at this stage because the project is performed in Oregon which does not charge sales tax. However, some elements of the project are likely to be performed or purchased within other states and tax assessed. This cost is dependent on the RA Contractor and methods chosen; therefore, potential tax is assumed to be within the range of uncertainty.

10-year construction period – The Pre-Final 90% RD cost estimate includes an annual budget derived from assumptions in the proposed RA schedule. All line-item costs are apportioned throughout the RA period based on the RA schedule.

5.0 COST ANALYSIS SUMMARY

Table 1-1 summarizes the cost estimate including the primary cost categories, the most probable projected cost, and the range of possible total costs within a 90% certainty as forecast by the cost model. The most probable cost projected by the probabilistic cost model is $930,308,019. The 90% certainty range has a low value of $874,607,352 and a high value of $997,611,332.

The following sections discuss the major divisions of the cost estimate, overview of the cost range reported by the model, and an overview of cost item sensitivity.

5.1 MAJOR DIVISIONS OF THE COST ESTIMATE

Table 1-1 shows the major divisions of the cost estimate organized by bid costs and RA Performing Party Costs. Bid costs are further subdivided into direct construction costs and indirect construction costs. Direct construction costs include the following major categories:

- Mobilization/demobilization
- Site preparation
- Surveys
- Structural
- Dredging, excavation, transportation and disposal
- Material procurement
- Material placement
- Riverbank habitat installation

Indirect construction costs include management, technical support and compliance monitoring, and site administration costs.

RA Performing Party Costs include agency oversight, operations and management, long-term monitoring costs, and structure relocations. RA Performing Party Costs are included in the Pre-Final 90% RD cost analysis as integrated components of the RA cost. It is recommended to consider extracting the RA Performing Party Costs from the RA construction cost based on the fact that the construction duration is approximately 10 years while the RA Performing Party Costs extend out to 100 years post construction.

5.2 COST RANGE REPORTED BY THE MODEL

The cost range reported by the model represents the 90% certainty range accounting for variability in unit costs and quantities. Each unit cost was assigned a range of variability to account for changes in price driven by economic conditions including changes in supply and demand for materials and services. Similarly, each unit quantity derived from the Pre-Final 90% RD was assigned a variability to account for uncertainty related to potential changes in site conditions between design and construction and uncertainties related to the spatial resolution of the site characterization data set on which the RD is based. The 90% certain range reported by the model shows a range of approximately -5.99% to +6.75% from the probable cost.

The probabilistic cost modeling approach projects a "most probable cost" in the context of a continuous probability distribution of potential costs. The probability distribution of costs informs risk-based planning decisions about cost contingency. The 90% certainty range reported on Table 1-1 and shown on Figure 2-1 indicates that there is a 90% certainty that the RA cost will be less than $997,611,332. The corollary to this is that there is a 10% certainty that the RA cost could exceed that value. The probabilistic cost estimate does not specify a contingency as an assumed percentage of total project cost. Instead, it provides the basis for cost managers to plan a cost contingency based on risk tolerance. If a 10% chance of cost exceedance is determined by cost managers to be an acceptable risk, then cost planning would establish a budget based on the 90% certainty range. The effective contingency in this example would be +6.75% of the most probable cost value.

5.3 COST ITEM SENSITIVITY

Figure 5-1 is a cost sensitivity chart of the top 10 cost items with the highest contribution to cost variance. Replacement of the Lagoon Wharf is shown as the largest contributor to potential variance of the overall RA cost. The second highest driver of potential cost variability relates to transport and disposal of dredged/excavated material. The cost sensitivity data support analysis of potential ways to reduce RA costs. For example, the cost effects of the Lagoon Wharf replacement motivated a focused analysis during design development of the Pre-Final 90% RD to evaluate alternative approaches to the remedy around the structure as well as alternative ways to replace the structure. As another example, the cost of transport and disposal of contaminated soil and sediment is magnified by the distance to the nearest available transload facilities and upland disposal sites. This highlights the potential for savings should a closer transload facility and/or disposal option become available between RD completion and RA construction.

10.10.10	Temporary Relocation of Floating Structures - Floating Dock, City Boat Ramp	27,000	LS	1	$27,000
10.10.11	Temporary Relocation of Floating Structures - US Navy Pier	9,600	LS	1	$9,600

(Subtotal) Subtotal - Structure Relocations: $1,071,800

(Subtotal) Subtotal - RA Performing Party Cost: $64,082,795

Total Estimated Project Cost: $876,741,086

Table A-2: Line Item Sources and Rationale Notes

Cost ID	Cost Item Description	Unit Cost Source	Unit Cost Notes
01	Direct Construction Costs (Bid)		
05	Mobilization / Demobilization		
01.05.01	Mobilization/Demobilization for Direct Construction Except Designated Structures	Passaic, EPJ	Estimated 10% of construction costs with procedural items listed separately. Apportioned mobilization for multiple construction years; more spent first year, less subsequent years. Uncertainty elevated because project will require annual mob/demob. Includes financial assurance and bonding, contractual overhead, development of closeout submittals, project record docs, bonds and insurance. This mobilization is based on construction costs that exclude stucture costs because each structure cost includes moblization individually. 10% of construction aligns with Passaic River. Notes below contain activities similar to those likely to be needed in SIB to characterize areas that mobilization cost may be needed.
01.05.01 (s1)	Pre-construction support facility		Pre-construction to include support facility-job trailers,sampling facility, equipment storage, employee parking. Est $10,000 per month.
01.05.01 (s2)	Upland Support Facility with Water Access		Estimated: Upland Support Facility with Water Access 5 acres-$510,000 per acre, escalated from 2014
01.05.01 (s3)	Fencing, Exterior Lighting, Security. Buildings		10,000 sf @$100 per sf, escalated from 2014
01.05.01 (s4)	Amenities		Amenities-lab , shower , locker rooms-$125,000;Guard shack, truck wash,sewer,water,electric-$110,000, escalated from 2014
01.05.01 (s5)	Stormwater Mgt. ,Paving, Pier/Dock		Stormwater Mgt. ,Paving, Pier/Dock@15,000 sf $2,740,000, escalated from 2014
01.05.01 (s6)	Water treatment for Decon Water		
01.05.02	Procedural Costs and Agency Submittals	Passaic	Incidental reports and procedural costs. RAWP and related plans, and structural submissions not included. Aligns with approach adopted in Passaic River project. Cost basis: 3 people working 6 months at contract start (3*$150/hr*8hrs*6mos (workdays)) Small comparative cost for indiv submissions; but retain as lump sum to account for stakeholder review process during development; has high uncertainty (elevated upper cost).
01.05.02 (s1)	Water Quality Monitoring Plan (WQMP)		
01.05.02 (s2)	Data Management Plan (DMP)		
01.05.02 (s3)	Temporary Erosion and Sediment Control Plan		
01.05.02 (s4)	Stormwater Management Plan		

Cost ID	Cost Item Description	Unit Cost Source	Unit Cost Notes
01.05.02 (s5)	Spill Prevention, Control, and Countermeasure Plan (SPCC)		
01.05.02 (s6)	Air Pollution, Noise, and Light Monitoring Plan (ANLMP)		
01.05.02 (s7)	Archaeological and Inadvertent Discovery Plan (AIDP)		
01.05.02 (s8)	Traffic Control Plan		
01.05.02 (s9)	Operations and Maintenance Plan		
01.05.02 (s10)	Water Management Plan		
01.05.02 (s11)	Health and Safety and Emergency Response Plans		
01.05.02 (s12)	Other ancillary plans		
01.05.03	Remedial Action Work Plan	Passaic	The development of all subordinate plans that comprise the Remedial Action Work Plan assume 60 hours of total development time for each report with a $40 hourly rate and 3.0 multiplier. Uncertainty of RAWP assembly remains elevated due to considerations regarding access, transload and disposal locations, work area establishment; all of which much be determined and documented in the Work Plan.
10	Site Preparation		
01.10.04	Utilities protection and restoration	EPJ	Limited utility survey data. Currently known utilities potentially within project site boundaries: Lumen optical. Variability in cost is high to account for uncertainties but weighed to lower cost due to available data suggesting limited utilities within project limits.
01.10.05	Site restoration	EPJ	Upland restoration such as asphalt, curbs, fences, etc. Because majority of work will be performed from the water, upland restoration requirements may trend lower; probability distribution weighs to lower cost.
(Subtotal)			
15	Surveys		
01.15.01	Initial Site Survey and Establish Controls	EPJ	Survey cost =$500 /acre Estimate 30 Riverbank Certification Units (RCUs) for the land part of the site. The water survey is part of pre dredging surveys. 30 RCUs x 0.48 acres per RCU ave. x $500 per acre =$7,200. Add $2,000 for survey plans. The definition and location of RCUs are specified in the Cap Design Technical Memorandum.
01.15.02	Preconstruction structural condition survey	EPJ	Divers to inspect underwater, engineer inspection by boat, and visual inspection of Pier decks + preparation of report. Direct Costs + Contingencies (therefore not included in probabilistic model) + Contractor Costs
01.15.03	Existing utilities survey	EPJ	Visual inspection/ GPR survey as required/EML survey as required + report and adjustment of baseline utilities as required

Cost ID	Cost Item Description	Unit Cost Source	Unit Cost Notes
			Direct Costs + Contingencies (therefore not included in probabilistic model)+ Contractor Costs
01.15.04	Progress and dredge/cap certification surveys	Passaic	Estimate 20 days per month (pre dredge, post dredge, post cap surveys) x $11,152 (escalated cost, per day)
01.15.07	As-Built Survey	EPJ	CCUs 1.32 river miles x 2 for coverage x 1 rm per day x $8,200 per day= 21648 > Escalated: 28116.12 RCUs 30 RCUs x 0.48 acres per RCU x $1,000 per acre = $ 14, 400 Reporting 40 Hours x 2 people x $150 per hour =$12,000 Total for As Built survey = $54,515.12
(Subtotal)			
20	Structural		
01.20.03	Limit Load and Temporary Support/Shoring of Existing Structures	EPJ	Temporary support/shoring/bracing or removal of existing bracing for access underneath existing structures. Structural steel piled structures will require little temporary work under this item. Timber structures will require removal of existing bracing and possible temporary bracing while the existing member is removed temporarily. Includes allowance to replace existing bracing with new due to deterioration.
01.20.05	Outfall Rebuild, large	EPJ	5% mobilization included
01.20.06	Outfall Rebuild, small	EPJ	5% mobilization included
01.20.07	Lagoon wharf (new structure)	EPJ	The unit cost was obtained from the 2025 KPFF estimate for the wharf that includes contractor direct costs and contingency.
01.20.08	Berth 306 (new structure)	EPJ	Direct Costs + Contingencies + Contractor Costs
01.20.09	Berth 307 (new structure)	EPJ	Direct Costs + Contingencies + Contractor Costs
01.20.10	USCG (toe wall, pile sleeves)	EPJ	Direct Costs + Contingencies + Contractor Costs
01.20.11	MC Pier (mid-slope pinning walls)	EPJ	Direct Costs + Contingencies + Contractor Costs
01.20.12	Berth 311 (breasting dolphin)	EPJ	Direct Costs + Contingencies + Contractor Costs
01.20.13	Berth 306 removal	EPJ	Berth 306 + 2 EA Walkways + 5 EA Dolphins Direct Costs + Contingencies + Contractor Costs
01.20.14	Berth 307 removal	EPJ	Berth 307 + 1 EA Walkway + 4 EA Dolphins Direct Costs + Contingencies + Contractor Costs
01.20.15	Berth 308 removal	EPJ	Berth 308 + 4 EA Dolphins Direct Costs + Contingencies + Contractor Costs
01.20.18	PoP dredge Base structural modifications	EPJ	Direct Costs + Contingencies + Contractor Costs
01.20.19	Structure &Upland monitoring	EPJ	Active monitoring of structures; settlement monitoring Direct Costs + Contingencies + Contractor Costs
01.20.20	Structural engineering design plan submittals	EPJ	Estimate: 5 people*$190/hr*8hrs*1yr (workdays) Hourly rate confirmed with Brain Maxwell 2025-08-22 Model range elevated to account for potential of additional geotechnical and civil engineering design elements.
(Subtotal)			

Cost ID	Cost Item Description	Unit Cost Source	Unit Cost Notes
25	Dredging, Excavation, Transportation &Disposal		
01.25.01	Required Dredging and In-Water Transportation (Open-Water) - Clamshell	VigorDredge	Estimate based on escalated 2015 Vigor dredging base cost which includes transport to Dalles but does not include free water processing (free water was pumped upland into Vigor drainage water treatment). Incidental: debris boom, silt curtain, related equipent. Assumes production rate of 1,150 cy/day.
01.25.02	Required Dredging and In-Water Transportation (Nearshore, below El 8 ft NAVD88) - Clamshell	VigorDredge	Based on open-water unit price then scaled to account for slower production rate (300 cy/day). Rate increase factor: 1150/300 cy/day = 3.8). Cost assumes that necessary water management controls will be included.
01.25.03	Required Dredging and In-Water Transportation (Restricted Access) - Clamshell/Excavator	VigorDredge	Dredging under structures Based on open-water unit price then scaled to account for slower production rate (250 cy/day). Rate increase factor: 1150/250 cy/day = 4.6) Cost assumes that necessary water management controls will be included.
01.25.04	Dredge Return Water Treatment and Discharge	Doty	Basis: avg cost from Electrocoagulation (EC) and Chitosan Enhanced Sand Filtration (CESF) pilot dredging in the Lower Duwamish Waterway, 2015. Average $/GAL escalated to 2025 using CWCCIS. Cost variability increased (0.85 - 1.7) to account for cost derived from 2015 pilot study.
01.25.05	Riverbank excavation (above El 8ft NAVD88) and in-water transport.	ODOT	Riverbank ex from ToB to El 13' (MLW). Covers both excavation using above-water earthwork machines placed on riverbank slopes, nearshore dredging during optimal tidal periods, and excavated material loading on barge via derrick. Majority of excavation work will be upland with above-water earthwork; therefore, the unit cost is based on ODOT common bank excavation bids. Unit cost obtained from average of large volume bids in 2025 ODOT data.
01.25.06	Water quality and turbidty control	VigorDredge	Estimate of 30 implementations of turbidity control measures at $120K per 1,000 lf at each typical implementation. Basis of typical cost derived from 2015 VigorDredge bid. Uncertainty of extent of required water quality control management remains elevated; assigned wider probability distribution.
01.25.07	TESC of upper riverbank excavation	EPJ	Coarse estimate of application of appropriate BMPs during riverbank excavation.
01.25.09	Dredged/Excavated Material Transload	VigorDredge	
01.25.10	Dredged/Excavated Material Upland Transportation, and Disposal (Subtitle D)	VigorDredge	Price combines 2015 costs for upland transport &disposal ($37.88/tn), and water removal and disposal ($122/tn on 20% of incoming material and escalated to 2025 dollars.
01.25.11	Identified Debris Removal (Subtitle D)	Stratford	
01.25.12	Identified Debris Upland Transportation and Disposal (Subtitle D) - Allowance	Stratford	
01.25.13	Contingency Re-Dredging - Allowance	VigorDredge	Same as open-water cost.
01.25.14	Standby Time - Allowance	LDW 90%	Allowance for situations in which the contractor is directed not to work.
01.25.15	Removal derelict Timber Piles, Incl. Dolphins & Groins	Terminal 1	Terminal 1 bids: $700 and $900 each. However, other sources suggest high variability; higher range of variability assigned to probability distribution.
(Subtotal)			

Cost ID	Cost Item Description	Unit Cost Source	Unit Cost Notes
30	Material Procurement		
01.30.01	Procure &Deliver Material T1C: <2.5" rounded gravel)	Terminal 1	Cost is based on Terminal 1 bid for granular "Fish Mix" which includes the combined tasks of procurement, delivery, and placement. The granular material price was based on quarry sourcing. The unit price for procurement and delivery is assumed to be approximately 1/2 of combined cost with the balance covering the cost of placement.
01.30.02	Procure &Deliver Material T2C: (Sand with GAC, 5%)	EPJ	(Addressed in Specific Cost Item Bases section)
01.30.03	Procure &Deliver Material T3: (unamended sand)	Terminal 1	Cost is based on Terminal 1 bid for granular "Fish Mix" which includes the combined tasks of procurement, delivery, and placement. The granular material price was based on quarry sourcing; however, it is anticipated that potential sand sources may expand at RAstart. The unit price for procurement and delivery is assumed to be approximately 1/2 of combined cost with the balance covering the cost of placement.
01.30.04	Procure &Deliver Material T4CB (ODOT 3" angular rock)	Terminal 1	Cost is based on Terminal 1 bid for granular "Fish Mix" which includes the combined tasks of procurement, delivery, and placement. The granular material price was based on quarry sourcing. The unit price for procurement and delivery is assumed to be approximately 1/2 of combined cost with the balance covering the cost of placement.
01.30.06	Procure &Deliver Material T6C (ODOT Class 50 Riprap)	Terminal 1	Cost is based on Terminal 1 bid for "Riprap" which includes the combined tasks of procurement, delivery, and placement. The combined price is then escalated 18% to 2025 dollars following an assessment of ODOT bid data. The unit price for procurement and delivery is assumed to be approximately 1/2 of combined cost with the balance covering the cost of placement.
01.30.07	Procure &Deliver Material T7A (ODOT Class 100 Riprap)	Terminal 1	Cost is based on Terminal 1 bid for "Riprap" which includes the combined tasks of procurement, delivery, and placement. The combined price is then escalated 18% to 2025 dollars following an assessment of ODOT bid data. The unit price for procurement and delivery is assumed to be approximately 1/2 of combined cost with the balance covering the cost of placement.
01.30.08	Procure &Deliver Material T8A (ODOT Class 200 Riprap)	Terminal 1	Cost is based on Terminal 1 bid for "Riprap" which includes the combined tasks of procurement, delivery, and placement. The combined price is then escalated 18% to 2025 dollars following an assessment of ODOT bid data. The unit price for procurement and delivery is assumed to be approximately 1/2 of combined cost with the balance covering the cost of placement.
01.30.10	Procure &Deliver Material T10R, ODOT 1.5" Dense Graded Aggregate	ODOT	ODOT Average 2024 Bids, large volume
01.30.11	Procure &Deliver Planting Soil P1 (silt loam, 2% organic)	LDW 100%	100% LDW estimates $36.25/ton. Converted to CY and escalated to 2025 using inflation rate (3.5%).
01.30.12	Procure &Deliver Compost P2 (silt loam, 10% organic)	EPJ	Estimated 20% increase of LDW unit cost for 2% organic silt loam (Planting Soil P1). 10% organic silt loam derived from mix of standard silt loam mixes, 1) 2% organic silt loam (75%), 2) 30% organic silt loam (25%).
01.30.13	Procure &Deliver GAC geotextile	Huesker	Tektoseal AC being assigned to explicit CCU's (Tea data). Scaled +8% to account for higher GAC loading that will be needed above the type in Huesker's estimate.
01.30.14	Procure &Deliver slope reinforcement bag lift materials	Vendor	Each bag is filled 1.25 cf of 70-80% granular sand/ 20-30 shredded topsoil mix. Unit price includes material procurement, delivery, and installation.

Cost ID	Cost Item Description	Unit Cost Source	Unit Cost Notes
01.30.15	Procure &Deliver slope reinforcement Envirolock bags	Vendor	Vendor (Envirolok) quote received 2025-08-01 for bulk unit purchase >5400 units.
01.30.16	Procure &Deliver ODOT00510.13 Granular Structure Backfill	ODOT	ODOT Average 2024 Bids, large volume, Portland region.
01.30.17	Procure &Deliver Geofabric Material	ODOT	ODOT2024 Bid data
01.30.18	Procure &Deliver jute netting	ODOT	ODOT2024 Bid data
01.30.19	Procure/Deliver Mulch	ODOT	ODOT2024 Bid data
01.30.20	Procure Sampling Port Boxes, large for open water	EPJ	Large Ports -$3254 per port x 105 CCUs=$341,670 Small Ports for Revetment areas -11 CCUs x$988=$10,868 Installation of Ports =$8,000 per day for 10 ports =116/10 =$92,800.
01.30.22	Procure &Deliver Planting Soil P3 (2% organic silt loam amended with 3% biochar)	EPJ	[LDW Topsoil ($54/cy)]+[Biochar ($70/cy) vendor quote]*1.15 factor for blending surcharge.
(Subtotal)			
40	Material Placement		
01.40.01	Place Material T1C: <2.5" rounded gravel)	Terminal 1	Cost is based on Terminal 1 bids for procure, deliver, and placement of small grain material wherein 1/2 of cost is estimated for placement only.
01.40.03	Place Material T2C: (Sand with GAC, 5%)	Terminal 1	Cost is based on Terminal 1 bids for procure, deliver, and placement of small grain material wherein 1/2 of cost is estimated for placement only.
01.40.05	Procure &Deliver Material T3: (unamended sand)	Terminal 1	Cost is based on Terminal 1 bids for procure, deliver, and placement of small grain material wherein 1/2 of cost is estimated for placement only.
01.40.07	Place Material T4CB (ODOT 3" angular rock)	Terminal 1	Cost is based on Terminal 1 bids for procure, deliver, and placement of small grain material wherein 1/2 of cost is estimated for placement only.
01.40.09	Place Material T6C (ODOT Class 50 Riprap)	Terminal 1	Cost is based on Terminal 1 bids for procure, deliver, and placement of riprap wherein 1/2 of cost is estimated for placement only. Cost escalated 18% following assessment of ODOT2024 bid data.
01.40.11	Place Material T7A (ODOT Class 100 Riprap)	Terminal 1	Cost is based on Terminal 1 bids for procure, deliver, and placement of riprap wherein 1/2 of cost is estimated for placement only. Cost escalated 18% following assessment of ODOT2024 bid data.
01.40.11	Place Material T8A (ODOT Class 200 Riprap)	Terminal 1	Cost is based on Terminal 1 bids for procure, deliver, and placement of riprap wherein 1/2 of cost is estimated for placement only. Cost escalated 18% following assessment of ODOT2024 bid data.
01.40.13	Place Granular Structure Backfill	Terminal 1	Cost is based on Terminal 1 bids for procure, deliver, and placement of small grain material wherein 1/2 of cost is estimated for placement only.
01.40.14	Place GAC geotextile	RSMeans	Placement estimate: 12 sy/hour, $320/hr for machine, operator, and two laborers.
01.40.25	PoP dredge base boat ramp aggregate placement	Terminal 1	Based on Terminal 1 bids and an estimated lower production rate anticipated for material on the boat ramp.
01.40.30	Place Sampling Port Boxes		Installation of Ports =$8,000 per day (similar to cost of mooring placement) for max of 10 ports/day for 36 ports in 18 performance units. Installation of sampling port similar is not a direct match to mooring placement; therefore, probability distribution spread is elevated.
(Subtotal)			

Cost ID	Cost Item Description	Unit Cost Source	Unit Cost Notes
50	Riverbank Habitat Installation		
01.50.01	Install slope reinforcement wrapped soil lifts	EPJ	Average of SF of installation face provided by Envirolok vendor.
01.50.02	Place Planting Soil P1 (silt loam, 2% organic)	EPJ	Estimated T&M unit cost equal to land-based placement of small-grained granular material ($80/cy)
01.50.03	Place Compost P2 (silt loam, 30% organic)	EPJ	Estimated T&M unit cost equal to land-based placement of small-grained granular material ($80/cy)
01.50.05	Place Planting Soil P3 (2% organic silt loam amended with 3% biochar)	EPJ	Cost is estimated to increase 50% to accommodate higher organic requirement.
01.50.08	Place Geofabric for Riverbanks	EPJ	Typical installed cost estimated to be 50% of material procurement and delivery
01.50.15	Procure/Deliver/Place Plants	ODOT	Average container installation of groundcover, shrub, and trees from ODOT bid data.
01.50.20	Riverbank vegetation irrigation	EPJ	Estimated 50,000 equivalent plant units (4 clumps of 4 emergent equated to 1 shrub or tree) at ~$15 (2025 $ for hand water via trucks – most costly) per plant = $750,000 (2025); 5 years (2025 $) is $3.75 million for irrigation

02	Indirect Construction Costs (Bid)		
01	Management, Technical Support and Compliance Monitoring		
02.01.01	Project Management	Passaic	PM $204,000 per year Three Operations Leaders- Dredging, Transload, Capping $131,000 per year x 3=$393,000 Quality Control Lead-$204,000 Support Staff -3 at $80,000 per year Costs include 40 % for Benefits Cost = $65,000 per month (before inflation)
02.01.03.10	Independent Quality Assurance Team	Passaic	IQAT-3 People 160 hours per month-CQA officer, Field Team Lead and H&S Officer $64,800 per month. 3.0 multiplier on raw labor $ per hour.
02.01.06	Environmental Compliance Monitoring (Water Quality Monitoring, Air/Noise/Light, and Inadvertent Discovery)	Monterey, Passaic	Basis-Monthly Cost Reference Document -SIB WQMP-Appendix to SIB CQA/QCP March 2025 During Dredging-Turbidity, Hardness, DO, pH with one year of Table 1-2 parameters for background via sondes. For turbidity measure one hour before active dredging starts, then 1 every 2 hours , including background For COCs Table 1-3 or "Focused list" -Assume Table 1-3 analytes , Total and Dissolved one sample per day during active dredging. Two water quality vessels one upstream, one downstream for turbidity measurements 6 days per week of active dredging, 4 weeks per month

Cost ID	Cost Item Description	Unit Cost Source	Unit Cost Notes
			Assume reporting of Compliance Sampling is done as part of weekly and monthly constriction reporting
02.01.06 (s1)	Turbidity monitoring	Passaic	Assume these are done by multi-parameter sondes that are provided with the sampling vessel 1 per vessel plus labor costs including the sondes. For Background Turbidity, hardness, DO and pH purchase two sondes at $2,000 each =$4,000 for duration of the project
02.01.06 (s2)	Analytical Costs	Monterey	For COCs 1 sample per day x 6 days per week of dredging x 4 weeks per month =24 samplings per month x 14 Samples for analyses = 336 samples for analysis Samples are analyzed for PAHs,metals,phthalates,VOCs, SVOCs,PCBs,Dioxins/Furans,Pesticides, Petro Hydrocarbons, 5 others per Table 1-3 WQMP (14 analytical sample groups) Analytical costs for these Total and Dissolved sample groups are $348,000 per month based on Monterey Labs Fee Schedule for 2025
02.01.06 (s3)	Sample Processing	Passaic	Sample processing costs-336 analytical samples /3 per hour x $130 per hour= $14,560 per month
02.01.06 (s4)	Sample Shipping	Passaic	336 samples/4 per cooler=84 coolers x $100 per cooler=$8,400 per month.
02.01.06 (s5)	Quality of Life Monitoring	Passaic	Quality of Life monitoring is done at the dredge (Air, Noise, Odors) -estimate is $5,000 per month per dredge (labor, sampling, analysis). From Passaic River 2014 Remediation Estimate.
02.01.10	TCLP metals analysis for Waste Characterization	EPJ	This is a component of pre-dredging landfill and regulatory acceptance of the sediment for disposal. Occurs during the RAplanning stage before dredging commences. The number of samples is standard landfill sampling frequency for waste designation and disposal. Vessel costs: $56,000 ($7,000 per day, 8 days) Field staff x3: $52,600 ($200 per hour, 10-12 hours per day, 8 days) Supplies/Equipment: $2,000 Field prep: $3,000 (creating/printing labels, field sheets, sample map, preparing supplies, prep meetings, etc) Travel &expenses: $6,000 (rough estimate, 3x per diem for 9 days, travel reimbursement) TCLP metals analysis of samples collected (30 samples * $280/sample) Total cost estimated $200K

Table A-4 Annual Expenditure Summary

Construction Year	Estimated Expenditure (2025 dollars)	Portion of Project Cost Total
2032	4,241,317	0.5%
2033	48,277,067	5.5%
2034	48,801,866	5.6%
2035	108,491,723	12.4%
2036	127,049,637	14.5%
2037	137,461,256	15.7%
2038	121,388,326	13.8%
2039	118,423,358	13.5%
2040	42,652,999	4.9%
2041	34,359,197	3.9%
2042	33,834,603	3.9%
2043	2,424,113	0.3%

Table A-5: Cost Model Variability Assignment

The following table includes the factors assigned to individual line item values and the upper and lower values calculated from the initial estimate that were then assigned to the probability distribution for each value. Select structure costs were assigned alternative probability distributions. The lagoon wharf (highlighted in yellow) was assigned a maximum extreme distribution and structures highlighted in blue were assigned gamma distributions. With All remaining values assigned lower and upper limits were assigned a triangle probability distribution that ranged between the low value and the upper value with the unit cost or quantity assigned as the most probable. Values lacking a minimum or maximum factor are fixed and unchanged in the model.

Cost ID	Cost Item Description	Lower Unit Cost Factor	Lower Unit Cost (by factor)	Unit Cost 90% RD	Units	Upper Unit Cost Factor	Upper Unit Cost (by factor)	Qty Min Factor	Qty, Min	Qty 90% RD	Qty Max Factor	Qty, Max

ENGINEER'S OPINION OF PROBABLE CONSTRUCTION COST - CONCEPT DESIGN

Vigor Portland Berth 302 to 305 Wharf Replacement - Bulkhead Option

By: Elie Hasso, Marty Gomez, Kelvin Kong

9/3/2025

Item Number	Description of Item	Quantity	Unit of Measurement	Unit Price	EXTENDED PRICE (QTY. x UNIT PRICE)	Notes
1	Mobilization / Demobilization	1	LS	$17,790,000	$17,800,000	1, 8
2	Existing Pier Demolition	1	LS	$5,300,000	$5,300,000	
3	Bulkhead Wall and Anchorage	1	LS	$93,100,000	$93,100,000	
4	Crane Rail Support Structure	1	LS	$3,300,000	$3,300,000	
5	Fender System	1	LS	$4,700,000	$4,700,000	
6	Temporary Shoring	1	LS	$3,500,000	$3,500,000	2
7	Ground Improvements	183,000	CY	$265	$48,500,000	7
8	Structural Infill	10,000	CY	$50	$500,000	
9	Earthwork	1	LS	$3,400,000	$3,400,000	3
10	Utilities	1	LS	$7,000,000	$7,000,000	5, 6
11	Electrical Utilities	1	LS	$5,200,000	$5,200,000	5, 6
12	Flexible Pavement	16,000	TON	$150	$2,400,000	4
13	Base Course	19,000	TON	$55	$1,000,000	4
				CONTRACTOR SUBTOTAL	**$195,700,000**	
				CONTINGENCY 35%	$68,500,000	
				OREGON STATE SALES TAX ON SUBTOTAL 0.00%	$0	
				ANTICIPATED CONSTRUCTION TOTAL IN 2025 US DOLLARS	**$264,000,000**	

Notes:

1 Mob / De-Mob Assumed ~10% of subtotal (assumes coverage for extended phasing duration of 6 in water work windows). Cost savings to mob / demob / management & yearly escalation (not captured) can be seen if an accelerated construction schedule is executed.

2 Temporary shoring is assumed to be purchased and not borrowed. Cost based on appx 2200ft of shoring length.

It is assumed that the majority of infill will be achieved using existing onsite materials, quarry spall to provide a working surface for

3 equipment, and ground improvements spoils. Additional fill required is captured in line item 8.

4 Pavement section assumes a 9 inch asphalt section over 12 inches base course

5 Includes Utilities Demolition.

6 Utility costs have been developed based on existing utility linear footages and analogous project unit costs.

7 Ground improvement consists of 100ft of DSM ($230/CY) and 20ft of Jet Grout ($500/CY). Weighted Avg ($265 / CY)

8 The costs presented in this estimate represent the baseline schedule which includes 6 in water work windows.

				ANTICIPATED CONSTRUCTION TOTAL IN 2025 US DOLLARS	**$346,000,000**	

Notes:

1 Mob / De-Mob Assumed ~12% of subtotal (assumes coverage for extended phasing duration of 9 in water work windows). Cost savings to mob / demob / management & yearly escalation (not captured) can be seen if an accelerated construction schedule is executed.

2 Temporary shoring is assumed to be purchased and not borrowed. Cost based on appx 2200ft of shoring length.

3 Unit cost assumes mix of disposal subtitle D and conventional facilities.

4 It is assumed that the majority of infill will be achieved using existing onsite materials, quarry spall to provide a working surface for equipment, and ground improvements spoils. Export is captured in line item 8.

5 Pavement section assumes a 9 inch asphalt section over 12 inches base course

6 Includes Utilities Demolition.

7 Utility costs have been developed based on existing utility linear footages and analogous project unit costs.

8 Ground improvement consists of 100ft of DSM ($230/CY) and 20ft of Jet Grout ($500/CY). Weighted Avg ($275 / CY)

9 The costs presented in this estimate represent the baseline schedule which includes 9 in water work windows.

Attachment C – Structure Cost Detail

The tables included in this attachment detail the cost items for the following structures:

Cost Line Item #	Structure Description
01.20.08	Berth 306 (new structure)
01.20.09	Berth 307 (new structure)
01.20.12	Berth 311 (seismic restraint)
01.20.18	PoP dredge Base structural modifications
01.20.11	MC Pier (mid-slope pinning walls)
01.20.10	USCG (toe wall, pile sleeves)

Berth 306 (new structure)				
Item Description	Quantity	Unit	Unit Rate	Cost
Mob/Demob	1	LS	$ 162,700.00	$162,700
Earthworks	-			
Abutment Excavation	1,235	CY	$ 100.00	$123,500
Abutment Backfill	1,094	CY	$ 115.00	$125,810
Pier Construction	-			
Supply Steel Pipe Piles - 30" Dia x 1" Wall	497,263	LBS	$ 1.50	$745,894
Supply & Install Shear Rings	599	LBS	$ 10.00	$5,986
Install Steel Pipe Piles - 30" Dia	16	EA	$ 14,275.00	$228,400
Pile Load Test	1	EA	$ 20,000.00	$20,000
Pile Concrete (Rebar/Pour)	30	CY	$ 1,800.00	$54,000
Abutment Wall /Wingwall Concrete (Form/Rebar/Pour)	58	CY	$ 2,500.00	$145,000
Abutment Approach Slab Concrete (Form/Rebar/Pour)	5	CY	$ 2,000.00	$10,000
Abutment Bearing Strip	16	LF	$ 150.00	$2,400
Deck Concrete Form/Rebar/Pour	254	CY	$ 3,000.00	$762,000
Ladders (L=35 LF)	2	EA	$ 11,150.00	$22,300
Bull Rail - 6" Dia Sch. 40 Pipe (36 ea connection points)	365	LF	$ 239.32	$87,350
Dolphin Construction	-			
Supply Steel Pipe Piles - 24" Dia x 1" Wall	1,293,472	LBS	$ 1.50	$1,940,207
Supply Steel Pipe Piles - 24" Dia x 3/4" Wall	0	LBS	$ 1.50	$0
Install Steel Pipe Piles - 24" Dia Battered	30	EA	$ 27,891.80	$836,754
Pile Load Test	1	EA	$ 20,000.00	$20,000
Pile Concrete (Rebar/Pour)	31	CY	$ 1,800.00	$55,800
Supply H Piles - 12" x 12" (Fender Piles)	59,200	LBS	$ 1.60	$94,720
Install H Piles (Fender Piles)	10	EA	$ 6,200.00	$62,000
Deck Concrete Form/Rebar/Pour	187	CY	$ 3,000.00	$561,000
Ladders (L=35 LF)	5	EA	$ 11,150.00	$55,750
Bull Rail - 6" Dia Sch. 40 Pipe (10 ea connection points per Dolphin)	195	LF	$ 318.21	$62,050
1150 SCK Cell Fender @ Mounting Accessories	5	EA	$ 12,500.00	$62,500
Structural Steel Steel Fender Frame	40,000	LBS	$ 7.50	$300,000
UHMW Pads for Fender	1,206	SF	$ 250.00	$301,600
Double Bitt Bollard	5	EA	$ 25,000.00	$125,000
Access Gangway Construction	-			
Supply Steel Pipe Piles - 24" Dia x 3/4" Wall	74,564	LBS	$ 1.50	$111,846

Berth 306 (new structure)				
Item Description	Quantity	Unit	Unit Rate	Cost
Install Steel Pipe Piles - 24" Dia	4	EA	$ 11,890.00	$47,560
Supply Helical Anchor Pile (Assume 18" Dia)	26	LF	$ 85.00	$2,210
Install Helical Anchor Pile (Assume 18" Dia)	4	EA	$ 750.00	$3,000
Intermediate Pier Structural Steel Cap	4,840	LBS	$ 7.50	$36,300
Abutment Footing & Approach Slab Concrete (Form/Rebar/Pour)	8	CY	$ 2,000.00	$16,000
Aluminum Prefabricated Gangway - 4' Wide	244	LF	$ 1,500.00	$366,000
SEE NEXT SHEET				
Upland Mooring Point Construction	-			
Supply Steel Pipe Piles - 36" Dia x 1" Wall	149,662	LBS	$ 1.50	$224,493
Install Steel Pipe Piles - 36" Dia	4	EA	$ 18,200.00	$72,800
Pile Load Test	1	EA	$ 20,000.00	$20,000
Pile Concrete (Rebar/Pour)	18	CY	$ 1,800.00	$32,400
Double Bitt Bollard	4	EA	$ 25,000.00	$100,000
Pier Utilities	-			
Potable Water				
6" Water Pipe c/w Hangers Under Pier Deck	140	LF	$ 500.00	$70,000
6" Water Pipe Buried	20	LF	$ 300.00	$6,000
Water Inlet Cabinet	1	EA	$ 20,000.00	$20,000
Water Connection Valves	2	EA	$ 5,000.00	$10,000
Water Inspection Chamber c/w Equipment	1	EA	$ 15,000.00	$15,000
Compressed Air	-			
2" Line Attached to Underside of Deck	140	LF	$ 200.00	$28,000
2" Line Buried	20	LF	$ 100.00	$2,000
Standpipe & Connections @ Deck	1	EA	$ 7,500.00	$7,500
Valve	1	EA	$ 3,500.00	$3,500
Electrical	-			
Conduit & Wire Attached to Underside of Deck	280	LF	$ 300.00	$84,000
Electrical Ductbank Burried	20	LF	$ 500.00	$10,000
Light Pole & Luminaire	1	EA	$ 7,500.00	$7,500
Shorepower Connection Cabinet	1	EA	$ 30,000.00	$30,000
Subtotal - Direct Costs				**$8,298,830**
Contingencies	-

Attachment D – Risk Register and Status

ID	Risk Category / Name	Description	Status	Risk Quantification			Notes/ Assumptions	Mitigation/Avoidance Measures
				Cost Impact ($MM)	Schedule Impact (months)	Likelihood		
Design Phase Risks								
	EPA/State Regulatory Approvals/Licenses	1. Final approved remedy (dredging vs capping) 2. Extended periods required to obtain and comply with approvals, permits or licenses for land access and operations	Queued	2-10	6-12	Low		1. Determine regulators' preferred approach to streamline permits, licenses and/or approvals to meet project timelines
	Contracting Strategy	Sub-optimal contracting strategy, contractor selection and ongoing management of activities, costs, and time	Queued	1-5	3-12	Moderate		Identify optimal strategy for contractor selection, contracting and management based on experience of designer and owners, noting any downside risks and fallback strategies
	Sediment Removal	1. Higher volume associated with selected remedial approach 2. Latent conditions associated with removal of the sediment	Partially complete	10-50	12-24	Low	50% RD includes a combined dredge/cap strategy that will either remove to clean sediment or sufficiently cap to isolate CoCs. This strategy has significantly reduced removal quantities compared with early estimates.	1. Designer to evaluate a range of possible approaches and propose a preferred approach to optimize removal volumes to meet requirements at lowest cost and/or highest effectivity of operations 2. Complete thorough on-site characterization of sediment to reduce risk of unknown latent conditions
	Capping	1. Larger capping area associated with selected remedial approach 2. Configuration/thickness of cap(s)	Partially complete	10-50	12-24	Low		Designer to evaluate a range of possible approaches and propose a preferred capping area and cap thickness design to meet requirements at lowest cost and/or highest effectivity of operations
	Shoreline Remediation	1. Larger extent of remediation required 2. Complex configuration of backfill/cap	In process	2-10	12-24	Low	Most of the shoreline is to be remediated with a beach mix cap up to a rock revetment to stabilize from slope failure and wave dissipation.	1. Site assessment shall fully characterize limits of required shoreline contamination. 2. Designer shall evaluate how to optimize tradeoff between excavation and capping to meet remediation requirements.

ID	Risk Category / Name	Description	Status	Risk Quantification			Notes/ Assumptions	Mitigation/Avoidance Measures
				Cost Impact ($MM)	Schedule Impact (months)	Likelihood		
	Contractor Management	Poor Contractor(s) selection or ongoing HSEC management	Queued	1-10	12-24	Moderate	Project special provisions will include language to qualify potential contractors.	1. Performance record qualifications and references shall be clearly identified in solicitation documents and verified during bid review. Contractors shall be disqualified for not meeting bid requirements. 2. Contractor performance requirements shall be fully spelled out in contract documents with financial penalties and/or rationale for dismissal for non-performance. Performance shall be reviewed monthly with reporting and discussion with Contractor for any non-performance issues and ramifications for continued non-compliance.
Construction Phase Risks – Intrinsic		*Risks that are potentially within the control of the design team or the RA contractor to minimize.*						
Internal Risks								
	Procurement	Unable to source sufficient quantities of equipment, construction materials or consumables (dredges, barges, transportation, etc.)	90% RD	1-20	12-24	High		In specs, require Contractor to designate a Procurement Lead responsible for developing a procurement plan for all major materials, equipment, and consumables using early-finish scheduling approach with monthly reporting on acquisition and stockpile status. Establish a required minimum lead time for critical elements during design phase and include as part of contract documents.
	Staging	Insufficient area for staging and/or storage	90% RD	1-2	6-12	Moderate	The project team is pursuing the use of City property at the south end of the lagoon for staging and ex-situ processing.	Alternative locations adjacent to SIB will be investigated.
	Dredging Operations	Failure to undertake dredging of contaminated sediment in an effective and timely manner	Queued	5-20	12-36	Low	Specs will include viable performance specifications that must be met.	Require Contractor to submit dredging schedule as a part of the operations plan and include daily penalties for inability to meet schedule.

ID	Risk Category / Name	Description	Status	Risk Quantification			Notes/ Assumptions	Mitigation/Avoidance Measures
				Cost Impact ($MM)	Schedule Impact (months)	Likelihood		
	Dredging Operations	Unexploded ordnance (UXO) is identified among debris to be removed.	Queued				Specs to include requirements to identify and dispose.	
	Sediment Processing	Process facility unavailable or method fails to meet treatment requirements	90% RD	10-50	12-36	Moderate	90% RD will consider dedicated processing site.	Define performance requirements within design documents with Contractor daily penalties for inability to meet performance requirements.
	Disposal Facilities	Insufficient capacity or failure of disposal facility during period of remediation	90% RD	10-50	12-48	Low	Consider secondary sites, potential reserved with retainer.	Ensure design identifies disposal facility with volumetric capacity and daily operational characteristics in excess of anticipated need.
	Transload	Insufficient capacity of transload site either from limited volume rate for the SIB project, but also that production rate may be further limited if the transload site is shared by other sites concurrently active within PHSS.	Queued	50-200	36-60	High		Transload sites will be investigated for compliance and capacity. Additionally, the creation of a new transload site will be evaluated.
	Disposal Facilities	Unknown contaminants in disposal material that preclude previously viable disposal facilities and/or require additional pre-disposal processing not included in design and cost.	Queued	10-200	36-60	Moderate		An expansion of selective sampling will be evaluated prior to RA to determine likelihood.
	Transportation	Insufficient capability or effective means to transport sediment to the processing and/or disposal facility	In process	10-200	36-60	Low	The cost estimate attempts to capture the economic risk of this requirement. It further highlights weight this risk imparts on the project. 90% RD will include an expanded exploration of transportation options.	Require Contractor to provide transportation plan sufficient to transport all materials to processing / disposal site with daily penalties for inability to meet performance requirements.

ID	Risk Category / Name	Description	Status	Risk Quantification			Notes/ Assumptions	Mitigation/Avoidance Measures
				Cost Impact ($MM)	Schedule Impact (months)	Likelihood		
	Existing Shoreline Structures Integrity	Damage/Failure of the existing shoreline structures	In process	10-250	24-60	Low		Identify during the design phase all sensitive shoreline structures with construction setback limits that are protective of structures and include daily checks by construction inspection staff to confirm setbacks are being honored. Include penalties for Contractor activities which encroach within setback limits and/or damage shoreline structures.
	Loss of Containment	Unacceptable or excessive in-situ movement, spillage or leakage of material during sediment removal or treatment operations	Queued	1-10	12-24	Moderate		Designer to identify containment requirements in design documents. Require Contractor to develop a containment plan which is inspected on a daily basis during construction, with weekly reporting.
	Construction Safety	Safety-related events arising from construction of project establishment, infrastructure facilities, and key treatment & disposal facilities	In process	0.5-1	6-12	Low		Require Contractor to develop and maintain a site safety plan that meets or exceeds OSHA requirements, with daily reporting of safety events.
	Occupational Health & Hygiene	Exposure to contaminant's during all operations	In process	0.2-0.5	3-6	Low		Require Contractor to develop and maintain a site safety plan that meets or exceeds OSHA requirements, with daily reporting of safety events.
	Emergency Response	Inadequacy of response to a major river or land based HSEC event	In process	1-20	6-12	Low		Require Contractor to develop and maintain an emergency response plan, with at least weekly confirmation of readiness of response materials by construction inspector.
	Demobilization & Disposal	Construction materials are not removed from site in a timely manner and/or improperly disposed	90% RD	0.1-0.5	3-6	Low		Require Contractor to develop a materials disposal plan identifying the materials to be disposed with allowable on-site quantities and an approved off-site disposal facility for each type of material to be disposed of off-site.

ID	Risk Category / Name	Description	Status	Risk Quantification			Notes/ Assumptions	Mitigation/Avoidance Measures
				Cost Impact ($MM)	Schedule Impact (months)	Likelihood		
	Compensatory Habitat	Compensatory habitat fails to meet regulatory requirements	90% RD	1-10	12-24	Moderate		Require Contractor to submit all materials, means and methods for creation, establishment and maintenance of the mitigation measures. Inspect at specified intervals to ensure compliance.
		Expanded utilities protection, relocate and/or restoration required.						Utilities survey at start of RA discovers presence of utilities outside of design estimate that would be impacted by construction activities requiring protection and/or restoration.
	Floating structure staging	Rental of storage space for floating structures that are temporarily relocated	90% RD	0.2-1	0	Moderate	This will occur if the operator of the structure needing relocation has no option for temporary placement.	The expectation is that all operators around the basin will impose preferential handling of any structures and that the cost of doing so is included in the estimated cost for the specific relocation.
Community Risks								
	Site Security	Incident or accident arising from unauthorized access to land or river operations	90% RD	0.1-0.3	3-6	Low		Require Contractor to develop a site security plan which includes onsite security personnel and video monitoring prior to start of construction and re-visit effectivity at least monthly during construction
	Owner-Operator Business Interruption	An owner/operator reports an interruption in business operations that was unanticipated in design conditions.	90% RD	5-10	1-3	High	(Added 2025-06-24)	In project specifications, insert contractor performance requirement to establish a real estate specialist as a liaison to communicate construction activity and coordinate potential impact business operations.
	River Operations	Accident between vessels, vessel and shore structure, or vessel and services	In process	0.2-2	3-6	Low		Require Contractor to develop a river operations safety plan
	Dust and/or Odor	Sub-optimal management of off-site dust or odor-related impacts arising from construction activities	90% RD	0.1-0.3	1-3	Low		Perform pre-construction baseline air quality monitoring and continuous monitoring during construction to provide early detection and control of possible exceedances

ID	Risk Category / Name	Description	Status	Risk Quantification			Notes/ Assumptions	Mitigation/Avoidance Measures
				Cost Impact ($MM)	Schedule Impact (months)	Likelihood		
	Transportation	Safety-related accident or environmental incident arising from offsite transportation of materials between sites and/or to disposal facility	90% RD	0.1-0.3	1-3	Low		Require Contractor's transportation safety plan to incorporate all possible interactions with offsite vehicles and/or community members
	Community/3rd Party Stakeholders	Disruption to and/or loss of amenity for the local community and/or loss of trust/reputation	90% RD	0.1-0.3	1-3	Low		Identify all possible amenity loss/disruptions during design phase and public outreach process and develop requirements for Contractor to pro-actively manage and limit activities which could cause possible loss / disruption
Construction Phase Risks – Extrinsic		*Risks that are outside the control of the RA contractor.*						
	Major Utilities Outage	Disruption in supply of power and/or water	90% RD	1-3	3-12	Low	Storm and/or offsite activities severs utilities feed(s) to site	Prepare contingency plan to supply utilities to critical site operations in case of outage
	Archaeological find	Encounter archaeological materials during streambank excavation	90% RD	0.1-0.5	1-3	Low	Need to pause excavation – relocate crew to next sequential excavation area	Archaeological analysis complete and reviewed by stakeholders > 6 months prior to excavation. Have archaeologist on site during excavation in high-risk areas. Have two or more work areas prepped at excavation start.
	Diesel fuel cost increase	Disruption in national supply causes >20% increase in cost of diesel fuel	90% RD	1-5	3-12	Low	Cost impact only significant during peak construction	Identify peak construction period, identify alternate suppliers and/or obtain fuel supply in advance via negotiated fixed price or create stockpile
	Heavy summer downpour	2-week long heavy rainstorm during summer construction	90% RD	0.1-0.3	1-3	High	Heavy long rainstorm will shut down upland excavation activities and slow in-water dredging due to complications in managing dredge materials	Investigate opportunities to perform dredge materials management in facility that is not impacted by rain, consider how upland excavation can be sequenced and/or erosion control options to allow excavation to move forth in heavy rain
	Undetonated Explosives	Discovery of historical explosives/ undetonated explosives	Active	0.1-0.3	1-3	Low	Pause local excavation, relocate equipment to safe work area	Survey site for unexploded ordinance ahead of contractor mobilization

ID	Risk Category / Name	Description	Status	Risk Quantification			Notes/ Assumptions	Mitigation/Avoidance Measures
				Cost Impact ($MM)	Schedule Impact (months)	Likelihood		
	Smoke Delay	Hazardous air quality due to wildfire smoke	Active	0.1-0.2	1-3	Low	Need to issue masks, shut down if extreme heat and/or low visibility	Monitor weather, fire index and air quality
	Public Process	Public opposition/ litigation	Active	0.2-0.4	3-12	Low	Possible shut-down of cleanup activities if public process identifies lack of sufficient/correct public process per EPA protocol	Ensure thorough public process is completed prior to advertisement of Remedial Action documents

OREGON DEPARTMENT OF STATE LANDS
DIVISION 145 REMEDIAL DESIGN COST

This page was intentionally left blank.

Attachment E – Oregon Division of State Lands Division 145 Remedial Design Cost

The following includes the completed calculator worksheet supplied by Division of State Lands used to estimate the DSL 145 cost. The parameters and definitions of inaccessible areas and land values follow the worksheet.

DSL 145 Calculator Worksheet

Project Area Name	SWAN ISLAND BASIN PROJECT AREA, CERCLA DOCKET NO. 10-2021-001 PORTLAND HARBOR SUPERFUND SITE PORTLAND, MULTNOMAH COUNTY, OREGON
Easement period (years)	60
Flat Rate (per sq ft)	0.7559
AV for land area in question (see adjacent land values table)	$13.11
Total days of construction (=active + inactive construction days)	3359
Area accessible during inactive construction period	399,158

Cost Formula = [(AV*Area*SDI)/30]*years authorized

This tool was developed solely to facilitate estimation of D145 costs during Portland Harbor remedial design. It does not establish or guarantee those costs, which will be based on the specifics of the final remedial design and actual use for which a D145 authorization is sought.

Color Key		These cells require project-specific inputs (see ReadMe tab for details). All orange cells have to be filled to get an accurate total cost for Division 145 costs.
		These cells represent fixed values for use in remedial design level estimates (see ReadMe tab for details)
		These cells represent results that are calculated based on the relevant inputs (see ReadMe tab for details)

Construction cost: first 30-year easement

	Area (sq ft)	SDI	Length of period (days)	Subtotal
Area inaccessible during active construction period	399,158	1	1220	$582,694.16

Area inaccessible during inactive construction period	0	1	2139	$0
Area accessible during inactive construction period	399,158	0.5	2139	$512,215

$1,094,909.34	Construction cost total: first 30-year easement

Post-construction cost: first 30-year easement

	Area (sq ft)	SDI	Years post construction	Subtotal
Buried contamination, cap, and/or other permanent in-water structures constructed as part of the remedy	3,445,355	0.5	20.78	$15,640,640.58
Additional area to which restrictions would apply	0	0.01	20.78	$0

$15,640,640.58	Post-construction cost: first 30-year easement total

Post-construction cost: second 30-year easement

	Area (sq ft)	SDI	Years post construction	Subtotal
Buried contamination, cap and/or other permanent in-water structures constructed as part of the remedy (sq ft)	3,445,355	0.5	30	$22,583,538.92
Additional area to which restrictions would apply (sq ft)	0	0.01	30	$0

$22,583,538.92	Post-construction cost: second 30 year easement total

Total Cost		
Construction cost (total days construction)	$1,094,909.34	
Post-construction cost (remainder of first 30-year easement period)	$15,640,640.58	
Post-construction cost (second 30-year easement period)	$22,583,538.92	
Total Cost	$39,319,088.84	

Adjacent Land Values for Assessed Value (AV) Calculation			
Tax Lot	Size (sq ft)	Land Value ($)	Cost per sq ft
R315695	301,000	$4,728,320	$16
R315697	484,387	$5,725,080	$12
R315704	185,566	$3,808,870	$21
R315705	126,324	$1,532,080	$12
R315711	151,589	$2,272,050	$15
R315626	193,406	$4,104,040	$21
R315728	223,463	$4,195,070	$19
R673573	18,295	$258,220	$14
R592199	312,761	$3,452,510	$11
R238891	172,498	$2,587,470	$15
R315949	65,340	$980,850	$15
R543792	28,733	$541,420	$19
R731034	2,806,135	$32,272,880	$12
TOTALS	5,069,497		

Rationale for Calculator Inputs

Construction Cost: First 30-Year Easement

Area Inaccessible During Active Construction Period

- The area that will be inaccessible during the active construction period is 399,158 square feet, calculated by dividing the total construction area (Cap Certification Units, Riverbank Certification Units, and Dredge Certification Units) into ten equal parts, with one tenth constructed each year over ten construction seasons.
- Areas were calculated using GIS and relying on the boundaries of Oregon State Submerged lands within the SIB Project Area, the area of Dredge Certification Units, the area of cap certification units, and the area of Riverbank Certification Units.
- Construction period is based on the RA construction schedule in the Pre-Final 90% RD as published in the Design Criteria Report (DCR), Figure 3-1 RA Schedule.
- The duration of inaccessibility is 1,220 days, which is calculated as 122 days per construction season over 10 construction seasons (July 1 – October 31, 2033 through 2042 inclusive).

Area Inaccessible During Inactive Construction Period

- The area that will be inaccessible during the inactive construction period is zero. The analysis assumes that in-water construction equipment will demobilize at the end of each in-water construction window and the SIB Project Area will remain accessible during the interim periods (Nov 1 through June 30).
- The duration of the inactive construction period is 2,139 days, which is the total construction period (3,359 days from July 1, 2033 – September 11, 2042) minus the active construction period total (1,220 days).

Area Accessible During Inactive Construction Period

- The area that will be accessible during the inactive construction period is calculated as the total parcel area minus the inaccessible areas.
- The duration of this condition is 2,139 days, which is determined as the total construction duration minus the cumulative duration of active construction (i.e., ten in-water work windows).

Post-Construction Cost: First 30-Year Easement

Buried Contamination, Cap, and/or Other Permanent In-Water Structures

- The affected area is 3,445,335 sq ft, which is based on GIS analysis of Cap Certification Units (77.696 acres) and Riverbank Certification Units (1.397 acres) located within the SIB Project Area and located on Oregon State Submerged Lands.
- The number of years after construction is calculated as the portion of a 30-year lease left after the construction period is complete. The calculator automatically determines this duration – value in this analysis is 20.78 years post construction.

Additional Area to Which Restrictions Would Apply

- The additional area to which restrictions would apply is assumed to be zero.

Adjacent Land Values for Assessed Value (AV) Calculation

- The tax lot information was obtained from *portlandmaps.com*.
- The parcel size was obtained in acres from portlandmaps.com and then converted to square feet using the standard conversion factor of 43,560 square feet per acre.
- The land value in dollars was obtained from the "Land Assessment" section on portlandmaps.com.
- The cost per square foot was calculated as the fair market value per square foot, weighted by the lot size across all adjacent riparian parcels.
- The basis of this calculation is unimproved land value only, with no site improvements considered.

Address	Property	Area (acres)	Area (sq ft)	Value (2024)
6767 N Basin Ave	R315695	6.91	300999.6	$4,728,320.00
6735 N Basin Ave	R315697	11.12	484387.2	$5,725,080.00
6211 N Ensign St	R315704	4.26	185565.6	$3,808,870.00
6208 N Ensign St	R315705	2.9	126324	$1,532,080.00
6208 S/ N Ensign St	R315711	3.48	151588.8	$2,272,050.00
6147 N Basin Ave	R315626	4.44	193406.4	$4,104,040.00
6135 N Basin Ave	R315728	5.13	223462.8	$4,195,070.00
5949 E/ N Basin Ave	R673573	0.42	18295.2	$258,220.00
3737 N Emerson St	R592199	7.18	312760.8	$3,452,510.00
5036 N Lagoon Ave	R238891	3.96	172497.6	$2,587,470.00
5160 N Lagoon Ave	R315949	1.5	65340	$980,850.00
5555 N Channel Ave	R731034	64.42	2806135.2	$32,272,880.00

Value Improvement Proposals 10
Considerations for Development of Value Engineering Proposals 10
Structures – Protection/ Demolition of Structures 11
Proposal #Structures 1 – Ensure the specs allow for use of small-scale spreader or conveyor approaches for placement of capping materials and armor/habitat stone beneath and around structures. 11
Riverbanks – Riverbank stabilization, remediation and restoration 12
Proposal #Riverbanks 1 – Establish an On-Site or Near-Site Combined Materials Staging and Processing Facility for Receipt, Processing, and Distribution of Materials for both Riverbanks and Capping 12
Dredging – Debris and sediment material dredging and management 13
Proposal #Dredging 1 – Modify the Specs to clarify that contingency dredging requirements only apply to Dredge to RAL DCUs. 13
Proposal #Dredging 2 – Pursue Site-Wide Consortium for Transloading and Transport of Dredged Sediments for Disposal 14
Proposal #Dredging 3 – Require consideration of Redundancy for critical pieces of equipment in all materials handling operations. 14
Capping – Engineered capping material procurement and placement 15
Proposal #Capping 1 – Modify the Cap Placement Tolerances for the CIL cap layer and apply all tolerances on an area-wide basis for Performance Monitoring Units 15
Proposal #Capping-2 – Modify the Specifications to allow for use of large-scale spreaders for placement of capping materials. 17

Proposal #Capping 3 – Modify the Specifications to allow for Use of Compartmented Bottom Dump Barges or other alternative spreading approaches for placement of armor stone or Habitat stone..... 17

Proposal #Capping 4 – Optimize Multi-Purpose Monitoring Stations for Cap Performance Assessment..... 18

General Proposals 19

Proposal #General 1 – Clarify the general sequencing of work. 19

Proposal #General 2 – Advocate for increase in the in-water work window or outright elimination of the window restrictions based on a cost comparison plus suggested mitigation and enhancement incentives. 20

Proposal #General 3 – Source Control issues should be resolved by convening an outside expert panel to assess 1) the findings of the SAR as compared to the EPA and State of Oregon comments on the SAR, and 2) the risk of recontamination of the SIB from existing sources. Based on the findings of such a panel, any needed source controls should be implemented and confirmed to be effective prior to initiating any RA in the SIB..... 21

EXECUTIVE SUMMARY

This Value Engineering Study provides proposed Value Improvement Proposals for the Swan Island Basin Project Area (SIB) of the Portland Harbor Superfund Site.

The study effort focused on the following aspects of the design:

- Structures - A general review of the approach to protection or demolition of structures.
- Riverbanks - Riverbank stabilization, remediation and restoration.
- Dredging - Debris and sediment material dredging and management; and,
- Capping - Engineered capping material procurement and placement.

A total of 12 Value Improvement Proposals are described in the study. The proposals were developed based on the review and analysis of the Draft 50% Design and several updated deliverables for the Pre-Final 90% Design for the project.

The site conditions for the SIB are complex, and the design effort was tailored to match specific remedy approaches to the varied conditions across the site. The resulting Proposals were both specific to each of the above design components and of a more general nature related to the overall remedy.

Introduction

Background

The Swan Island Basin Project Area (SIB) of the Portland Harbor Superfund Site is an industrialized lagoon located between river miles 8.1 to 9.2 of the Willamette River. The SIB was developed and industrialized over many decades and is now considered an "active navigable industrial waterway". In-water structures, developed riverbanks, and varied water depths are found within the site. Contaminants of concern are present in the SIB sediments to include dioxins/furans, TPH-Dx, PAHs, PCBs, metals, and tributyltin (HGL 2025c).

EPA Region 10 issued a Record of Decision (ROD) for the Portland Harbor Superfund Site in January 2017 (EPA 2017). The selected remedy for the overall site calls for combinations of dredging/excavation, capping, in-situ/ex-situ treatment, enhanced and/or monitored natural recovery, and institutional controls. Certain riverbanks would be remediated by a combination of soil excavation, chemical isolation in place, stabilization, and restoration. A portion of the Swan Island riverbanks will be addressed through the reconstruction of the Lagoon Wharf.

The Remedial Design (RD) for the SIB project is currently being conducted by HydroGeoLogic, Inc. (HGL). The draft 50% RD for SIB calls for a combination of dredging, capping, natural recovery, and riverbank restoration, consistent with the overall ROD-selected remedy approach.

HGL engaged Mike Palermo Consulting, Inc. to conduct this Value Engineering (VE) study for the SIB as part of the ongoing RD effort. I was engaged as a Value Engineering Consultant, solely responsible for conduct of the study. My credentials are summarized in Appendix A. Please note that all first-person language used in this report refers to Dr. Michael R. Palermo, the sole employee of Mike Palermo Consulting, Inc.

This report documents the results of the VE Study to include considerations in developing proposals for potential cost savings and descriptions of those proposals.

VE Process and Participants

The parameters for conducting a VE Study are documented in EPA memoranda and documents (EPA 1995 and EPA 2005). In accordance with these documents, HGL conducted a VE Screening for the 50% RD effort in March 2025 (HGL 2025b). Based on the relatively high cost of several components of the design, the VE Screening report established the need for this formal VE Study.

The VE Screening effort and the Scope of Work for this VE study identified the following design components as the focus of the study:

- Structures - A general review of the approach to protection or demolition of structures;
- Riverbanks - Riverbank stabilization, remediation and restoration;
- Dredging - Debris and sediment material dredging and management; and,
- Capping - Engineered capping material procurement and placement.

The development of the dredging prism for SIB was also evaluated in the VE Screening effort but was not recommended as an area of evaluation in this VE Study.

The Scope of Work for the VE study originally defined by HGL called for a timeline of 7 weeks for the study. Materials initially provided to me for review and analysis was the Draft 50% Design. Additional products of the on-going 90% design effort were in development concurrent with the VE study, and the timeline was extended as additional products were made available.

Preliminary Value Improvement Proposals were sent to HGL at the beginning of week 4 of the study and discussed in a mid-point virtual meeting in week 5 of the study. Several 90% design products were provided to me following the mid-point meeting, and those products were considered in updating the VE proposals as the study progressed. Therefore, some aspects of the design addressed in the Preliminary Proposals were undergoing modifications in the 90% design work. Any updates of the proposals resulting from these 90% inputs are appropriately noted in the Proposals.

Throughout the study, HGL staff interacted with me to resolve questions and details on issues as needed.

Documents Reviewed and Summary of Key Design Elements

Documents Reviewed

This study required review and analysis of a number of documents. The sheer volume of information needed for the design was huge, with several thousands of pages of text, data tables, figures, drawings, etc. Obviously, I did not review and analyze all the information and data in detail. But that type of extensive review was not needed for this VE study. I focused my effort on those design components identified by the VE Screening, and for these components, further focused on the details I saw as needed to identify proposals. The process of review and analysis of the documents continued throughout the study timeframe as proposals were identified and described, additional documents were made available, and the report prepared and finalized.

Documents reviewed and analyzed for the study are listed as follows:

- Value Engineering Study Documents:
    - Value Engineering Screening (HGL 2025b)

  - EPA Guidance on VE Studies (EPA 1995 and EPA 2005)

- Pre-50% Documents:
  - Record of Decision (ROD) (EPA 2017)
  - Final Sufficiency Assessment Report (SAR) Revision 1 (HGL 2025a)
  - EPA and State of Oregon comments regarding the SAR (EPA 2025 and State of Oregon 2025).

- 50% Design Documents:
  - 50% Design Criteria Report Volume 1 (HGL 2025c)
  - Plans Volume II (HGL 2025d)
  - Preliminary Specifications and Drawings Volume III (HGL 2025e)

- Pre-Final 90% RD Documents:
  - 90% Design Criteria Report (HGL 2025f)
  - Cap Design Technical Memorandum (Volume I, Appendix E [formerly D])
  - Riverbank Design Technical Memorandum (Volume I, Appendix D)
  - Dredging Design Technical Memorandum (Volume I, Appendix H [formerly G])
  - Geotechnical Design Technical Memorandum (Volume I, Appendix I [formerly H])
  - Structural Design Technical Memorandum (Volume I, Appendix J [formerly I])
  - 90% Specifications and Drawings

The full citations for the above documents are listed in the References section of this report.

Key Design Elements

The 50% Design documents initially provided for review and analysis for this report included Text, Figures, Plans, Drawings and Specifications. The Design Criteria Report (DCR) with Appendices (HGL 2025c) is the main document describing the various components of the design. As would be expected, some specifics were not fully developed in the Draft 50% Design documents. Key documents developed as part of the Pre-Final 90% Design were also provided for review and analysis after the mid-point of the VE study. These included updated Technical Memoranda for Dredging and Capping and the Technical Memorandum for Riverbanks.

The scale of the SIB and the variability of site conditions dictated an extensive design effort. My focus was on the four design components identified in the VE Screening, and the key design elements for these design components are summarized below.

Structural Design

The Structural Design is concerned with implementing the remedy in areas adjacent to and in some cases underneath existing structures within the SIB. The Structural Design Technical Memo in Appendix J of the DCR states that structural design utilizes a Performance-Based

Design approach. Appendix J of the DCR contains the results of an evaluation of each of the 23 structures within the SIB, including details of the solutions for each structure and drawings for each structure. Four of the structures are slated for demolition, including the Lagoon Wharf. Slope stability considerations remain an issue, since some of these structures are at the limit of acceptable factors of safety.

An important issue is the potential for damage to the structures during the implementation of the remedy in areas around and beneath the structures. The design did not include any specifics regarding the potential risk of such damage, but local damage, slope stability, and capping integrity are concerns due to the confined spaces between and under the structures. The responsibility to implement the RD without damaging the existing structures is placed on the contractor and the final design that they will develop.

Riverbanks Design

The Riverbanks design component was described in the Riverbank Design Technical Memo prepared as part of the Pre-Final 90% Design documents (HGL 2025h). This memo lays out an essentially prescriptive design component for restoration of the 2.3 miles of riverbanks surrounding SIB. The riverbanks are defined as extending from the top of bank (at various elevations) to the mean high water level at +13 feet datum. The riverbanks are presently armored with stone or covered in vegetation, and the underlying soils are contaminated similar to the sediments. The ROD requires the remediation of the riverbanks to protect the in-water remedy of the sediments in the SIB.

The remedy for the riverbanks consists of a conventional approach to remove contaminated armor stone and surface soils and replace with clean materials. Some areas will require flattening the slopes due to seismic stability concerns.

The requirements for excavation and grading are straightforward and would require conventional equipment. This is all work “in the dry”, so this remedy component consists of excavation of contaminated soils and subsequent placement of a new chemical isolation layers for seepage-based migration to include chemical barriers of topsoil amended with biochar where vegetation is planted. Where no vegetation is planted (i.e. where erosional or structural concerns prevent vegetative cover), reactive core mat will be used on slopes steeper than 3H:1V up to a maximum design slope of 2.15H:1V. The VE Screening identified construction access, materials management, and work sequencing as areas of concern for implementation of this remedy component.

Dredging Design

The Draft 50% Dredging Design Technical Memo is Appendix G of the DCR. That memo was updated as part of the Pre-Final 90% RD. Key elements of the Dredging Design include the definition of the dredging prism, the determination of a preferred dredging method, the methodology for selection of the remedy option for specific areas within the SIB, and the

logistics of transloading and transport of dredged sediments for landfill disposal. The design calls for disposal in approved landfills, which will be at distance from Portland Harbor.

The dredging design defined the dredging depths across the SIB, essentially the dredging prism. But the equipment and approaches for dredging, transload, transport and disposal will be left to the Contractor.

The dredging prism was defined across the SIB in 10 ft by 10 ft grid cells. Three options for a remedy approach were considered for each grid cell, Dredge to RAL, Dredge and Cap, and Cap only. For the Draft 50% design, the Dredge to RAL option was removed from consideration due to deeper required depths near structures, resulting irregularity in required depths and requirements for transition, and time required for confirmation sampling and testing. For the 90% design, the Dredge to RAL option was restored, but only to specified areas subject to disturbance by spudding.

The concentrations of contaminants and depth of contamination vary across the grid cells, so a decision-tree approach was defined and used for selection of the remedy for each of the grid cells. As would be expected, the selected remedy approach by grid cell resulted in a tight-knit patchwork for remedy approach across the site, that would be difficult to apply to the dredging and capping operations. So, the tight-knit map was converted to larger Dredging Certification Units (DCUs) for the Dredge to RAL and Capping Certification Units (CCUs) for the Dredge and Cap and Cap Only remedy approaches.

Large debris will be identified and removed prior to dredging. Mechanical dredging was the recommended sediment dredging approach. I fully agree that this is the best dredging approach, especially considering the requirement for landfill disposal. Hydraulic dredging would require removal of additional small debris prior to dredging, would require dredging pipelines within the basin with potential obstruction to navigation, and would require significant dewatering requirements associated with landfill disposal.

The VE screening identified the materials management aspect of the dredging design component as a key element. The requirement for landfill disposal presents challenges due to the lack of nearby landfill facilities with the capacity needed for the SIB project and/or the overall PHSS. Also, there are no existing transloading facilities within or near the PHSS with adequate throughput for such a large project.

Capping Design

The Draft 50% Capping Design Technical Memo was updated as part of the Pre-Final 90% RD (HGL 2025f). The Capping Design is understandably the most complex design component. Capping is the principal mode of achieving the remedial goals and is applied to the majority of the SIB site area. EPA and USACE guidance on capping design requires evaluation of multiple aspects of the design to include defining design objectives, selecting capping materials, defining

required cap materials and thicknesses for chemical isolation and physical stability, and more. These were appropriately evaluated in this cap design.

The CAPSIM software was the tool applied for determining the chemical isolation requirements for the caps, and was applied to specific Cap Certification Units (CCUs) defined as subareas of the overall site. CAPSIM is perhaps the most developed cap design tool available for evaluating the chemical isolation aspect of cap design. This application was the most detailed I have seen, and required an extensive number of simulations to address the size of the SIB and variability of the contaminant concentrations.

The design for physical stability of the caps included evaluation of several drivers for potential erosion of the cap to include currents, wind waves, prop wash, dry dock activities, and outfalls. These drivers were mapped for the SIB area to determine the requirements for the armor layer of the cap. The resulting design called for application of cap designs applied to the specific conditions across the site.

A total of 5 alternative cap designs were developed to meet the various needs for chemical isolation and physical stability and were assigned to the respective CCUs and RCUs. But, as with the Dredging component, the equipment and approaches for placement of the caps will be left to the Contractor.

The VE Screening identified material availability, quarry production of cap material, and competition for transloading capacity as issues of concern. These are concerns related to importing needed materials for the caps, and these concerns are the mirror image of those concerns for taking dredged sediments off site for disposal in the Dredging component.

Value Improvement Proposals

Considerations for Development of Value Engineering Proposals

Several considerations influenced the identification of VE Proposals and the level of detail describing the proposals:

- **Complexity of the Design and Implementation** - The RD effort included quite complex design efforts (especially for capping) as well as more straightforward design elements. The complex design effort yielded a surprisingly straightforward design for the capping and dredging RD components. Overall, I found the design to be soundly based in accepted approaches and tools we see in agency guidance and the state of the practice. However, the implementation, essentially how to build it, will again be quite complex and presents significant logistical issues. So, the identified Proposals mostly pertain to the implementation of the RA.

- **Design vs. Construction** – The design lays out the dredging prism and the cap components in detail. The means and methods for construction are largely left to the contactor. So, the lion's share of the specific equipment and approaches for construction will be left to the RA Contractor, with plans to be submitted in the RAWP process. This limits the opportunities in the VE study to identify specific recommendations for improvements in effectiveness and/or reductions in cost for many of the construction specifics, at least at this point. Also, a close review of the Specifications was useful to identify possible changes that would result in saving of time and costs related primarily to the construction. For me, the draft Specifications were the most fertile ground for identifying possible cost savings.
- **VE Study Consultant Role** – My prior experiences with formal VE studies each involved a VE study panel with several participants with diverse technical backgrounds. For this VE Study, I was engaged as a Value Engineering Consultant, solely responsible for the study. This limited the level of detail and precluded specific estimations of potential cost savings for the Value Savings Proposals that were identified. For example, I am not a cost estimator, so my experience with costing is limited to a more general knowledge of cost drivers. These limitations of working solo were to a degree mitigated by prompt feedback from the HGL team to answer questions and provide requested information.

The Value Improvement Proposals that follow include those specific to each of the above design components followed by proposals of a more general nature. These general proposals focus on both potential cost savings and the overall success of the RA.

Several of these proposals were developed as preliminary proposals based on review and analysis of the 50% design documents available at the start of the VE Study. After the mid-point meeting in week 4 of the study, HGL provided additional deliverables for the 90% Design. In these instances, the Proposals were updated to reflect the 90% design information.

Structures – Protection/ Demolition of Structures

Proposal #Structures 1 – Ensure the specs allow for use of small-scale spreader or conveyor approaches for placement of capping materials and armor/habitat stone beneath and around structures.

The 90% Specifications require that Contractor means and methods for placing materials under existing structures should be selected such that damage to any portion of the existing structures should be prevented. The Specs do not include any further details on how this could be accomplished.

The work around and beneath the structures is going to be tedious and slow-going compared to the work on more open riverbanks. Use of conventional earth moving equipment may not be possible in some cases. And, use of such equipment may present higher risk of damage in some cases. Some hand-labor work may be required.

The use of spreader or conveyor approaches for material placement may provide added protection to structural components and allow for material placement at lower cost as compared to direct bucket placement. For placement in tight areas, smaller versions of these spreaders could be sized to operate from Flexifloats. For some areas under structures, placement using a rainbowing approach may be feasible. Illustrations of several types of small scale spreaders, both mechanical and hydraulic, are shown in Appendix B, Figures 1 through 4. See also Proposal #Capping 2 to follow that includes a brief description of several spreading equipment types and how they operate.

For placement of larger armor/habitat stone around structures, use of Flexifloats with small front-end loaders for spreading may achieve similar savings and lower risks to structures as compared to direct placement from larger mechanical equipment.

Once selected, the Contractor should provide details in the RAWP describing how the reconstruction of the slopes and placement of the caps will be performed without potentially damaging the structures.

Riverbanks – Riverbank stabilization, remediation and restoration

Proposal #Riverbanks 1 – Establish an On-Site or Near-Site Combined Materials Staging and Processing Facility for Receipt, Processing, and Distribution of Materials for both Riverbanks and Capping

Note that this proposal in some aspects may apply to both the Riverbanks and Capping design components, since both of these components require large volumes of clean materials imported to the site for use in restoration of the riverbanks and for cap placement. The possible means of transport of such large volumes include by water, barging the materials directly to the SIB, and by land by trucking or rail. The selection of a transport mode will depend on the means of placement, which will differ for the riverbank work as compared to the sediment capping work. This proposal is focused on a potential land-based facility located at SIB and used only for incoming clean materials, primarily those needed for the land-based river bank restoration work.

Sand, GAC, armor stone, and habitat stone are materials that will be sourced from locations at distance from the site and in large quantities. The materials handling requirements for the Riverbank work and the Capping components are similar. Importation of materials for Riverbank restoration, and perhaps for sediment capping, could be transported to a staging facility at SIB by rail or by truck, depending on the source and quantities. Materials could be stockpiled, blended, and distributed from one central facility on site at or nearby SIB. A combined materials facility would reduce duplication and potential interference between the two components of Riverbanks and Capping.

The use of such a facility for the Capping component would be efficient if a shore-based supply of capping material could be distributed hydraulically from shore to the on-water capping

placement equipment. If not, the capping material would likely be directly transported by barge directly to the placement equipment.

In future years, a centrally located facility at the SIB could also be utilized for the wider Portland Harbor site, with other Performing Parties potentially reaping some cost savings by not requiring construction of other similar facilities for multiple projects. And, the SIB parties could possibly reap cost savings in the form of income from use of the facility by the other projects.

This proposal also mirrors the Consortium concept described in Proposal #Dredging 2. That proposal pertains to contaminated materials going out from the SIB to transloading and subsequent transport to landfills for disposal.

Dredging – Debris and sediment material dredging and management

Proposal #Dredging 1 – Modify the Specs to clarify that contingency dredging requirements only apply to Dredge to RAL DCUs.

Note that this proposal was initially developed based on review and analysis of the 50% design documents available at the start of the VE Study. The Draft 50% Design called for dredging portions of the SIB, followed by capping of these dredged areas. Other areas would be capped with no prior dredging. The caps to be placed over the entire site are isolation caps, not merely post-dredging residuals caps. If the caps are effective for CCUs, the caps would be effective as well in DCUs post dredging. Therefore, I saw no technical basis for requiring a contingency Re-Dredging step for any CCUs that were dredged and then capped based on the 50% design and 50% specifications.

Re-dredging for a DCU as defined in the specs would require more than 2 weeks of time to sample and analyze plus the time required to actually accomplish the re-dredging. Limiting this re-dredging requirement would save significant time and costs. Therefore, I had recommended that the Specifications should be revised to clarify that contingency dredging requirements would apply only to Dredge to RAL DCUs.

At the mid-point meeting in week 4 of this VE study, HGL indicated that the ROD-selected remedy had been updated in the Pre-Final 90% RD to reflect that even though the ROD selected remedy for SIB was predominantly a Dredge and Cap approach, there will be some DCUs that will be Dredged to RAL. Subsequently, the 90% Dredging Technical Memorandum identified specific DCUs that would be Dredge-to-RAL. The contingency dredging requirement would therefore be appropriate for those DCUs only, and would not be applied for the majority of the DCUs within the SIB. Based on these changes, this proposal can be considered as adopted.

Proposal #Dredging 2 – Pursue Site-Wide Consortium for Transloading and Transport of Dredged Sediments for Disposal

The Dredging design now calls for Contractor identification of an off-site facility for transloading and transport of contaminated sediments removed by the dredging from the SIB. This facility would be intended to receive contaminated materials from the SIB for transport to a designated and approved landfill.

There is no design per se for the transloading and transport to landfill requirements for the SIB unit. The selection of landfills, transloading, and transport requirements are left to the contractor.

The SIB Project Area is the first in line for the PHSS. The cost estimate at this point references a timeline of 4 years from completion of the RD to bidding, an additional year for preparations post-award, and 8 years for open water construction. This is potentially a 13 year or greater timeframe to completion. The SIB contractor is tasked to identify facilities and landfills from those now existing, but there are multiple Project Areas in the Portland Harbor site. All the Performing Parties associated with these units will face the same needs with respect to transloading and transport. But assuming the Contractor selection approach for each unit of the Portland Harbor site seems inefficient.

This proposal is a suggestion to potentially save time and costs for both the SIB Project Area and the other such units to come. If the RPs for all Portland Harbor units would or could work together, forming a Consortium of sorts to forge cooperative arrangements, more efficient use of facilities, staging, materials, etc. could be pursued. With more RPs working together, the costs for these remedy components could be reduced over time, based on economy of scale, considering the huge increase in material volumes to come in future years. Cost participation in such a venture could be settled within the framework of the Cost Allocation Process.

The timeframe for SIB may not allow for the Consortium process to address the needs in the early phases of SIB work, but savings could be realized for the later phases for SIB. HGL has indicated that there are no orders currently in place for any other Areas of the Site, so the Performing Parties are still in the early stages of "working together". But this could change if significant cost savings could be gained by all parties.

Proposal #Dredging 3 – Require consideration of Redundancy for critical pieces of equipment in all materials handling operations.

Redundancy for critical pieces of equipment or components for the materials transloading and transport is crucial. If a dredge is idled due to a breakdown somewhere in the chain of operations, the cost is significant. I refer here to off-loading equipment such as cranes, front loaders, numbers of barges, towboats, etc. This is not a direct cost savings item. Rather it is an

important cost avoidance item. Hard lessons related to this topic were learned for the Hudson River site regarding redundancy for off-loading. This proposal applies to both the transloading and transport of dredged sediment and debris from the site as well as capping materials to the site for placement. The inclusion of redundancy provisions of this nature could be included in the specifications or could be included as a proposal requirement in the bidding process.

Capping – Engineered capping material procurement and placement

Proposal #Capping 1 – Modify the Cap Placement Tolerances for the CIL cap layer and apply all tolerances on an area-wide basis for Performance Monitoring Units

The Preliminary 50% Specifications and 90% Snapshot Specifications included a table of cap placement tolerances for both CIL and EPL components for the caps. When I first reviewed those specifications, my initial impression was that the +3/-0 inches tolerance for the CIL cap layer was "tight". These specs also stated that "Placement tolerances will be measured using analysis of high-resolution multibeam hydrographic survey data…" These multibeam data would be processed to produce a grid with 3x3 foot grid cells. The specs also state that "the Contractor shall correct placement deficiencies and conduct additional associated Placement Post-Construction Surveys to the satisfaction of the Project Representative and at no extra cost …"

In my subsequent review of the 90% Specifications, I saw that the same table of tolerances and the same language was included for measurement and addressing deficiencies. After again considering the "tight" tolerance of +3/-0 inches for the CIL, and the method of determining the results by small grid cells, I now believe that these tolerances are overly constraining, and that it would be very difficult to efficiently and economically construct these caps on the scale required for the SIB.

The -0 inches tolerance as now described in the specs means that the CIL layer thickness must meet the 12-inch thickness with no tolerance for under-placement. If the 12 inch thickness is not met, additional material would be required. The +3 inches tolerance would allow for a maximum of 3-inches overplacement for payment, with a 6-inch allowable overplacement. If the overplacement exceeds 6 inches, the material would require removal. The specs are defined such that these tolerances must be met for every 3x3 foot grid cell.

I have two recommended modifications regarding these tolerances, one being a direct change of the tolerance for the CIL layer, and the second being a change in the approach to confirm successful cap placement.

First, modify the cap placement tolerances for the CIL layer to +3/-3 inches.

With a -0 inch tolerance requirement, the contractor is incentivized to place more cap material to meet the 12-inch thickness or greater 100% of the time. This means there will be a significant net surplus of cap material placed overall. This equates to more time spent to accomplish the

placement. More cap material is a good thing with respect to cap performance. But more time equates to more cost to the contractor. The basis of payment for this part of the work is paid by the area capped, not the volume of cap material placed. So, the contractor bears a higher cost for the time spent to do the work plus the higher cost of the additional volume of cap material the contractor must purchase and transport to do the work. Also, the tendency to place additional material to meet the minimum required thickness can result in a higher risk to the contractor to place material at thickness above the maximum allowed overplacement. This would require remedial work at high cost to the contractor. I believe these multiple factors would result in higher bids.

Second, evaluate compliance with the tolerances on an area wide basis for each Performance Monitoring Unit (PMU).

In the most recent 90% documents, the concept of CCUs for capping certification has been altered to aggregating the 130 CCUs into 18 Performance Monitoring Units (PMUs) for the purpose of monitoring cap performance.

Each PMU would be comprised of a large number of the 3x3 foot grid cells. As the specs are written now, if the tolerances are not met in a given grid cell, remedial work is required to correct that specific grid cell. It would be very expensive to re-mobilize equipment to add material or remove material over small surface areas. This approach would lead to higher bids.

With an area wide approach, the survey results for each grid cell would be evaluated as a group for the entire area of the PMU. A benchmark level of success would dictate success or failure for the entire PMU. Other large scale sediment sites, the most notable being the Hudson River, have used 90% of the area within the tolerances as the benchmark required for a "pass" with no requirement for remedial work. If more than 10% of the area did not meet the benchmark, remedial work would be required for that PMU. This area-wide approach is recommended for all the cap layers, both CIL and EPL.

This proposal is made assuming that an efficient method of placement of the capping materials is used as discussed in proposal #Capping 2. Specialized spreading equipment has been utilized at several large capping sites for spreading of cap layers in an acceptably efficient rate of progress and at acceptably consistent layer thicknesses. Examples of these equipment types are described in Proposal #Capping 2.

If the tolerances remain as "tight" as they are now, I believe bidders will substantially increase their bids due to the potential slow down of the work and the higher potential need for remedial actions, and/or there will be fewer bidders submitting bids for the project.

Proposal #Capping-2 – Modify the Specifications to allow for use of large-scale spreaders for placement of capping materials.

This proposal is similar to Proposal #Structures1. Both the 50% and 90% Specifications as written imply bucket placement as the approach for placement of the isolation cap layers (mixtures of sand and GAC and bedding stone). Cap placement by the bucket load will be a slow process with higher costs. With the exception of tight areas such as around structures, large scale spreading equipment would be efficient in spreading the materials at a much faster rate over most of the large open water area of the SIB, with potentially large cost savings.

Such spreaders include both mechanical spreaders that employ gravity release of material through manifold arrangements or direct hydraulic feed to spreaders for placement of sand/GAC cap layers. Such spreaders have been very effective for capping large areas at sites such as Fox River WI, Onondaga Lake NY, and Gowanus Canal NY. The nature of these equipment types also allows for real-time monitoring of cap layer thicknesses directly from the floating plant, providing a more consistent placement of layer thickness. Also, some of these spreaders allow for direct hydraulic feed of the cap material to the spreader from the shore, eliminating the need for barges to shuttle material to the spreaders as would be required for bucket placement.

Depending on the size requirements for the bedding stone component of the caps, the manifold equipment type may be a possibility for the bedding stone placement. The bedding stone is characterized as a 2 to 3 inches diameter stone, and larger scale manifold equipment could be efficient for spreading this layer.

Examples of large-scale spreaders are shown in this Report's Appendix B, Figures 5 through 7.

This proposal would also involve reconsideration of the requirement for a Verification Placement above water to demonstrate the equipment is effective. Such a practice placement demo above water would be impractical for large equipment spreaders as described in this proposal. These spreaders have a proven track record, but an in-water demo could be conducted.

Proposal #Capping 3 – Modify the Specifications to allow for Use of Compartmented Bottom Dump Barges or other alternative spreading approaches for placement of armor stone or Habitat stone

There are significant requirements for armor stone placement in the project. Both the 50% and 90% Specifications implied the use of bucket placement for the stone. Barge-based placement of armor stone has been done for placement of large armor stone. These barges are compartmented such that the compartments can be uniformly loaded and simultaneously opened such that a larger surface area, on the order of 20 by 60 feet can be covered with a single load. Applications of such equipment should be allowed in the Specifications. A requirement for a demonstration of their effectiveness should be considered, as is now mentioned in the 50% Specifications.

Figure 8 in Appendix B is a photo of one type of compartmented bottom-dump barge.

Proposal #Capping 4 – Optimize Multi-Purpose Monitoring Stations for Cap Performance Assessment

Appendix N of the DCR deals with the Project Area Monitoring Plan (PAMP), and the PAMP at this 50% Design stage was focused for the most part on the Cap Performance Assessment. The topics for that assessment include porewater sampling, depositional sediment monitoring and physical integrity of the armor and habitat cap layers.

The PAMP calls for collection of pore water samples, sediment surface samples, and elevation surveys to determine cap integrity. Passive samplers are recommended for the pore water data. In the 50% documents, these pore water data would be collected for every CCU located in an upwelling area. So, the numbers of stations would have been significant.

This Proposal was included in the first draft of this report submitted in week 5 of this VE study. That draft proposal dealt with the concept of using multi-purpose monitoring stations for collection of the required data for pore water and cap integrity. Using a multi-purpose station will save time and cost by meeting multiple requirements with the same monitoring event.

In my original proposal, the settling plates would be composed of a plate with a marked vertical riser. The plate would be set on the sediment surface prior to cap material placement. They would need to be heavy to avoid damage during armor stone placement. It is important to monitor consolidation with the settlement plates to distinguish between consolidation of the underlying sediment versus the erosion or movement of the overlying capping layers. These same stations could be used to observe and sample any surface sediment accumulation by adding a sediment trap to the station.

In week 7 of the study, the 90% Pre-Final Specifications (HGL 2025i) and 90% drawings (HGL 2025j) were made available for my review. The 90% specs provided a description of a more robust concept for cap monitoring "ports", essentially large cast concrete frames with steel "lids", each about 10 feet square and each with 12 openings for housing the peepers. Each peeper would be analyzed at 3 depth intervals in the CIL. Figure 126 of the 90% drawings shows the configuration of the ports. The specs call for three of these ports to be placed in each of 130 CCUs. The sampling data would be collected in year 1 following the remedy construction and in 5 year intervals thereafter for 15 years.

The scope of the monitoring effort as laid out in the 90% specs can be summarized as:
130 CCUs x 3 ports x 12 openings x 3 sampling intervals at depth = 14,040 samples.

The concept seems workable, but would be expensive to construct and place properly. In my view, the scope of the effort as originally described is unnecessarily excessive. I propose that the scope of this effort be optimized and should focus on a lesser number of port locations, concentrating on those locations with the higher underlying concentrations of COCs and with the higher upwelling rates. I would recommend the scope be reduced to perhaps 20 to 30 ports.

The scope would then be summarized as:
Between 20 to 30 ports x 12 openings x 3 sampling intervals at depth = Between 720 to 1080 samples.

Fewer ports would reduce the construction and installation cost substantially. And, reducing the number of samples for analysis would reduce the analytical costs substantially. I would note that even with this reduction in scope, the SIB program would be the largest scope of cap performance monitoring ever undertaken, at least to my knowledge.

I believe the location/configuration of the PMUs and the specific locations and numbers of ports in the PMUs should be clearly defined in the drawings, essentially as part of the design. These locations should not be left to the Contractor. As mentioned above, these locations and numbers of ports should be defined considering areas of higher underlying concentrations of COCs and with the higher upwelling rates.

Also, note that such heavy ports will likely induce localized consolidation due to their weight, unlike a lighter settling plate arrangement. So, the ports may not provide a good base from which to evaluate consolidation.

General Proposals

Proposal #General 1 – Clarify the general sequencing of work.

The Draft 50% RD Specifications contain a sequencing section in Part 2, but this section covers only a general sequence of work. This proposal addresses the need to clarify the sequence of work that would be allowed on a site wide basis, considering the size of the site and the scheme of DCUs, CCUs and RCUs.

HGL indicated there is a 300 ft buffer to be maintained between dredging while capping is on-going. But this raises the question as to how many locations within the SIB could be active with dredged and/or capping activity. It is a large site and different schemes could be considered with respect to sequencing dredging and capping concurrently in multiple CCUs/DCUs.

The simple rule of thumb, dredging from upstream to downstream, applies to unidirectional flow conditions (as for the main stem river), and may have application within DCUs depending on the size of the DCU. But this rule of thumb has limited application for SIB at large, which is a dead end offshoot of the river channel. The capping rule of thumb is to cap from downslope to upslope. This would apply for work within any of the CCUs.

Clarification is needed on sequencing to address these related questions:

- That dredging could occur in multiple DCUs concurrently;
- That structural work be completed prior to riverbank restoration in a given RCU;

- That riverbanks can be worked concurrently with adjacent dredging DCUs;
- That any set of DCUs must be done prior to any capping within or adjacent;
- That capping could occur in multiple CCUs concurrently; and,
- That it is possible to identify a sequence of DCUs and CCUs area wide most favorable for reducing impacts.

Proposal #General 2 – Advocate for increase in the in-water work window or outright elimination of the window restrictions based on a cost comparison plus suggested mitigation and enhancement incentives.

Fish Windows are a major influence on the cost of this remedy as proposed in the 50% design. I know protection of resources is a concern for both the tribes and communities at large. However, I would advocate for further discussion on that issue with all the stakeholders, focusing on an additional cost estimate comparing the window parameters now being considered with expansion and/or elimination of the window restrictions. Considering we are now looking at a 13-year or longer project overall, a generous increase in the work window or an outright elimination of the restriction would equate to large cost savings, based on inflation considerations alone. Increasing work windows would also result in direct cost savings on reduced mob/demob. With an extension, the total time of exposure of resources to in-water work across the total span of the remedy would be the same, just compressed into a reduced overall timeline. With outright elimination of the restrictions, the timeline for completion of the remedy could possibly be cut in half, with the environmental benefits of the completed remedy gained over an additional 5 years or more.

Consideration of changes in the window restrictions should include supporting issues and/or arguments that should be added to discussions or negotiations. The work windows are normally applied to in-water construction activities that support commercial or governmental requirements to support navigation improvements or harbor development and maintenance. In the case of Portland Harbor Superfund, the in-water activities at issue here are based on the improvement of the environment of the site. If restrictions are eased, Portland Harbor would benefit from years of restored environmental quality, coming to fruition in a few years as compared to the lengthy timeline of 13 years with the restrictions.

In addition to the environmental quality benefits, other mitigation measures or enhancements could be considered. Habitat creation or improvements in upstream reaches either within the overall PHSS or upstream from the site would be a possibility. Considering that the overall cost for the full Portland Harbor site may be on the order of several billion dollars, an enhancement related to public outreach and education would be appropriate for such an immensely large environmental project. One possibility is a publicly accessible visitor center and environmental outreach center for education of the public (especially young people) on how the restoration was accomplished and what the restoration means to the Portland community.

Proposal #General 3 – Source Control issues should be resolved by convening an outside expert panel to assess 1) the findings of the SAR as compared to the EPA and State of Oregon comments on the SAR, and 2) the risk of recontamination of the SIB from existing sources. Based on the findings of such a panel, any needed source controls should be implemented and confirmed to be effective prior to initiating any RA in the SIB.

This proposal is not linked to any direct cost savings for the RA. Rather, the proposal is in direct response to a critical issue related to the overall integrity of the RA.

The principle "Control Sources Early" is stated clearly in the EPA Superfund Sediment Guidance (see P 2-21 of EPA 2005) and in EPA OSWER Directive 928.6-08, Appendix A of that same EPA 2005 document.

HGL conducted a *Final Sufficiency Assessment Report* (SAR) in January of 2025 (HGL 2025a). This SAR report was conducted by HGL as required by the Administrative Settlement Agreement on Consent (ASAOC) between the U.S. Environmental Protection Agency (EPA) and the Performing Parties. The SAR is an extensive study, at over 2000 pages, of contaminant sources and the potential of those sources compromising and RA in the SIB and other areas of the overall Portland Harbor site.

The Executive Summary of the SAR states:

> This SAR identifies the presence of a substantial risk of post-RA recontamination attributable to a combination of sources. The dominant risk of recontamination is the downriver transport of sediments containing contaminants of concern (COC) into the SIB with a notable but much less significant secondary contribution from ongoing stormwater discharges to the SIB. These recontamination risks support the need for EPA and the Oregon Department of Environmental Quality to pursue characterization of uncontrolled sources associated with the identified potential risk of recontamination pathways followed by implementation of additional source control measures before proceeding with RA.

EPA and the State of Oregon presented detailed comments on the SAR to support the position that Source Controls now in place were adequate and that RD should not be delayed based on source control issues (EPA 2025 and Oregon DEQ 2025).

This proposal is to further evaluate this issue by convening an outside expert panel to review the information from both sides and provide recommendations. There is time to do this, and the issue is of such importance that we cannot leave this hanging with a disagreement on the facts of the matter.

Appendix A: Qualifications for Dr. Michael R. Palermo

I am a consulting engineer with experience in Dredged Material Management and Contaminated Sediment Remediation since 1974, serving both private sector and government clients. I was employed as a civilian with the U.S. Army Corps of Engineers (USACE) from 1967 to 2003. While with USACE, I served as a Research Civil Engineer and Director of the Center for Contaminated Sediments at the Engineer Research and Development Center (ERDC) at the Waterways Experiment Station (WES), where I managed and conducted both research and applied studies for the USACE, EPA, Department of Justice (DOJ), National Oceanic and Atmospheric Administration (NOAA), U.S. Navy, and others. I also managed the WES/ERDC research focus area for contaminated sediments. Since entering private practice in 2003, I have provided design services, technical review and oversight for clients, both in the U.S. and abroad, on a wide range of sediment remediation and navigation projects.

I received my Bachelor of Science (BS) and Master of Science (MS) degrees in Civil Engineering from Mississippi State University and a PhD degree in Environmental and Water Resources Engineering from Vanderbilt University. I am a Registered Professional Engineer (Mississippi and North Carolina) and a member of the Western Dredging Association (WEDA) and the American Society of Civil Engineers (ASCE). I have served as an adjunct professor at Texas A&M University and Mississippi State University. I also serve as Associate Editor for the Journal of Dredging Engineering, a peer-review publication of WEDA.

I have authored or co-authored well over 200 publications in the area of dredging and dredged material disposal technology and remediation of contaminated sediments. These include the USACE 1987 Engineer Manual Confined Disposal of Dredged Material, USEPA 1998 Guidance for In-Situ Subaqueous Capping of Contaminated Sediment, USACE 1998 Guidance for Subaqueous Dredged Material Capping, USEPA 2005 Contaminated Sediment Remediation Guidance for Hazardous Waste Sites, commonly known as the “Superfund Sediment Guidance”, USACE/USEPA 2008 Technical Guidelines for Environmental Dredging of Contaminated Sediments and USACE 2015 Engineer Manual Dredging and Dredged Material Management.

I have participated in a number of Value Engineering Studies in past years to include Grand Calumet River 201; Boeing Plant 2 Duwamish River 2012; Waukegan Harbor 2016; and Spirit Lake MN 2018.

I have had prior experience related to the Portland Harbor Superfund Site, acting as a consultant for the Port of Portland during the Feasibility Study stage 2016-2017 and later as an expert for the Port during the Design Cost Allocation Process in 2024.

CONSTRUCTABILITY ASSESSMENT TECHNICAL MEMORANDUM

This page was intentionally left blank.

CONSTRUCTABILITY ASSESSMENT TECHNICAL MEMORANDUM
PRE-FINAL 90% REMEDIAL DESIGN
SWAN ISLAND BASIN PROJECT AREA
PORTLAND HARBOR SUPERFUND SITE
PORTLAND, MULTNOMAH COUNTY, OREGON

The Constructability Assessment Technical Memorandum presents a summary of constructability assessment efforts for the Pre-Final 90% Remedial Design (RD) for the Swan Island Basin (SIB) Project Area within the Portland Harbor Superfund Site (PHSS) in Portland, Multnomah County, Oregon. The HydroGeoLogic, Inc. (HGL) team (RD Team) performed the work on behalf of the SIB RD Group based on the requirements of the PHSS Record of Decision (ROD) (EPA, 2017a) and the Administrative Settlement Agreement and Order on Consent (EPA, 2021a). This memorandum includes references to the previously published Basis of Design Report (BODR) (HGL, 2024a) that was approved by EPA in December 2024. References are also made to the previously published Pre-Design Investigation (PDI) Evaluation Report (ER), (HGL, 2024b) which was approved by the U.S. Environmental Protection Agency (EPA) in January 2025.

This memorandum follows the work completed in Section 6.0 Remediation Implementability Assessment of the BODR (HGL, 2024b). This assessment identified and evaluated factors that were important to consider for the timely, cost effective and successful conclusion of this remediation project. These factors informed the Draft 50% RD and prompted the constructability review as part of the progression to the Pre-Final 90% RD to produce a constructable design.

Section 1.0 presents the process for the constructability review of the RD. Section 2.0 describes the constructability considerations for technology assignments outlined in Section 6.1.1 of the BODR (HGL, 2024a) that were made in the Pre-Final 90% RD. Section 3.0 summarized construction activity considerations that have informed elements of the RD, along with resulting particulars outlined in the specifications.

1.0 CONSTRUCTABILITY REVIEW

A constructability review of the Draft 50% RD was completed as an important design quality assurance milestone. Led by the contractor specialists, the review focused on providing a design that could be built efficiently, safely, and in accordance with regulatory and environmental standards. It prompted targeted updates to the Pre-Final 90% RD that enhanced buildability without compromising the complex technical decisions that informed the original Draft 50% RD development.

Table 1-1 summarizes the key tasks completed during the constructability review for the Pre-Final 90% RD, along with a general description of the review and the specific design deliverables where the outcome of the review is detailed.

Corporate Headquarters
11107 Sunset Hills Road, Suite 400
Reston, Virginia 20190
703-478-5186

Table 1-1 Constructability Review Tasks Summary

Constructability Review Task	Description	Deliverable Informed
Review of Draft 50% RD Documents	Identified constructability issues in specifications and drawings.	90% RD Drawings and Specifications
Evaluation of Dredging and Material Handling	Informed TODP; addressed equipment, access, sediment removal, and logistics.	TODP (Volume II, Appendix O), Specifications 35 24 20, 35 24 20.01
Construction Sequencing and Scheduling	Structured to minimize rework and environmental impacts; informed RA schedule.	90% RA Schedule (Volume I – Design Criteria Report, Figure 3-1), RAWP (to be prepared by RA Contractor)
Technology Assignment Consideration Review	Reassessed the considerations made in BODR (HGL, 2024a) Section 6.1.1; confirmed feasibility in the Pre-Final 90% RD.	90% RD Drawings and Specifications
Debris and Structure Considerations	Integrated debris removal and structural access limitations into design.	Drawings, Specification Section 35 24 20, Structural Design TM (Volume I, Appendix J)
Waterway Use Authorizations and Remedial Use Authorizations	Addressed Oregon DSL waterways use authorizations modifications and remedial activity authorizations (OAR 141-145).	90% Cost Estimate, Specification Sections 0135 43, 01 41 00, 01 41 26
Habitat and Riverbank Restoration	Incorporated restoration to meet RAO 9; ensured constructability of excavation, fill, and planting of riverbanks.	Riverbank Design TM (Volume I, Appendix D), 90% RD Drawings and Specifications
Construction Equipment and Facilities	Identified required equipment (e.g., dredges, barges, cranes) and support infrastructure (e.g., field offices, docks).	Specification Sections 01 52 00, 35 24 20
Material Procurement and Handling	Aligned specs with ODOT standards; planned for specialty materials and transloading logistics.	TODP and Material Specifications including Sections 31 00 00, 31 05 19, 31 34 19, 31 37 00, 31 62 10 31 62 16.19, 32 90 00, 33 05 25, 35 37 10.
Logistics and Constraints	Considered in-water work periods, utilities, environmental protection, and facility operations; emphasized Facility Owner/Operator coordination.	90% RA Schedule and Specification Sections 01 14 00, 01 31 00, 01 35 43, 01 41 00
Facility Owner/Operator Engagement	Integrated feedback from facility owners/operators; recommended approach for continued engagement with Facility Owner/Operators.	90% RA Schedule and RAWP
Dredging Productivity and Equipment Availability	Estimated production rates by equipment and site conditions; evaluated availability of barges, cranes, and haul trucks.	Dredging Design TM (Volume I, Appendix H), 90% RA Schedule
Risk Identification and Mitigation	Identified risks and developed mitigation strategies.	Risk Register (Volume I, Appendix K), 90% RD Drawings and Specifications

Notes:
DSL = Department of State Lands
OAR = Oregon Administrative Rules
ODOT = Oregon Department of Transportation
RA = Remedial Action
RAO = Remedial Action Objective
RAWP = Remedial Action Work Plan
TM = Technical Memorandum
TODP = Transportation and Off-Site Disposal Plan

Discussion of review tasks and their impact on deliverables is summarized in the following sections.

2.0 TECHNOLOGY ASSIGNMENT CONSIDERATIONS

All technology assignment considerations identified in Section 6.1.1 of the BODR (HGL, 2024a) were thoroughly evaluated during the development of the Draft 50% RD. As the design progressed to the Pre-Final 90%, those technology assignment considerations that remained relevant following the 50% constructability review have been further addressed and are discussed in the section below. The Pre-Final 90% RD includes measures to support a constructable design in relation to the following technology assignment considerations and none of the following items are considered obstacles to executing the remedy as designed.

2.1 DEBRIS

Classification and identification of the debris has been described in the BODR (HGL, 2024a) and the PDI ER (HGL, 2024b). Known items of debris have been noted in the Debris Removal and Demolition series in the drawings; however, the RA Contractor will be responsible for confirming debris during the RA.

The RA Contractor is responsible for debris removal, as specified in Section 35 24 20 – Remedial Dredging, Barge Dewatering, and In-Water Transportation. Dredge productivity analysis has indicated that performing a separate, pre-dredge debris-removal effort would be an inefficient overall approach to the work. The RA Contractor will equip sediment barges with ecology block debris bins to sort and contain debris larger than 6 feet (ft), to meet the bid item specified in Specification Section 35 24 20*,* that pays by the ton for debris larger than 6 ft. While a full-scale pre-dredge debris removal effort would not efficient, certain large debris items identified during the PDI, such as potential vessels, may require a specific removal operation prior to dredging. It is anticipated that this removal effort for large, isolated items will occur prior to the production dredging of a specific grid prism. Removal of debris prior to placement of cap material will be required in areas where no dredging is planned.

Informed by selections made during the 90% RD, the debris removal is not expected to pose an impediment to successful RA construction.

2.2 WORK AROUND STRUCTURES

A structure-by-structure review has been performed, summarized in the Structural Design Technical Memorandum, (Volume I, Appendix J), and consideration given to the physical constraints and challenges the RA Contractor would face when attempting to dredge underneath each structure. To the extent feasible, only capping is proposed under structures in the Pre-Final 90% RD. These design elements also consider the geotechnical considerations made throughout the RD, summarized in the Geotechnical Design Technical Memorandum, (Volume I, Appendix I).

Constructability of capping and erosion protection was addressed in terms of RA Contractor access and equipment limitations. Capping material size has also been reviewed and adapted, generally resulting in smaller material size; this supports multiple placement methods that may be required due to restricted access, such as excavator buckets, conveyor systems, stand shooters, or if

necessary, placement by hand. No concerns regarding general revetment constructability were noted within the review except for within pile fields under structures. Revetment construction under structures is unavoidable in some of the more energetic areas; therefore, alternative placement methods (e.g., conveyor systems) and less efficient construction are anticipated.

2.3 WATERWAYS USE AUTHORIZATIONS AND REMEDIAL USE AUTHORIZATION REQUIREMENTS

The Oregon Department of State Lands (DSL) requires waterway use authorizations for most docks and other structures in or over Oregon state-owned lands. These include most docks, floats, and other structures 2,500 square ft and larger that are not in wharf use. Change of ownership requires an assignment of the waterway use authorization.

The RD Team has engaged with shoreline facility owner/operators at several stages throughout the RD process to obtain information on their structures for assessing impacts from excavation, dredging, and capping beneath and adjacent to the in-and-over water structures. Impacts to structures or related uses caused by implementation of RA, including structure removal, modification or replacement, may result in modification of a DSL waterway use authorization.

Remediation conducted under an EPA administrative order and subsequent associated habitat restoration require remedial activity authorization in accordance with Oregon Administrative Rules (OAR) Chapter 141, Division 145. The proposed RA includes environmental dredging, capping, and habitat restoration activities that are subject to the requirements of OAR 141-145. Although, standing alone, different types of remedial activity might qualify for different types of OAR 141-145 remedial authorizations, DSL will generally evaluate the proposed RA as a whole and may use the form of authorization that accommodates the longer-term use. For example, these rules consider soil and sediment caps to be permanent structures. Permanent structures require an Easement. Obtaining the necessary remedial activity authorizations required by OAR 141-145 will be the responsibility of the RA Performing Parties.

2.4 HABITAT CONSIDERATIONS

Riverbanks in the SIB Project Area include riparian and aquatic habitat. Contamination within riverbanks must be controlled to achieve the goals of Remedial Action Objective (RAO) 9 which is to “reduce migration of contaminants of concern (COCs) in riverbanks to sediment and surface water such that levels are acceptable for human health and ecological exposures” (EPA, 2017a).

Soil excavation and dredging is required to regrade riverbanks for structural purposes, to stabilize over water and shoreline structures, and to prevent erosion of shoreline surface and subsurface soils to achieve RAO 9. Excavation along the riverbanks will also remove existing vegetation. Following the excavation and dredging, fill, capping materials, and shoreline protection materials will be placed to complete the RA.

The design of the fill, capping, and shoreline protection includes replacing and creating habitat. Riverbank habitat restoration will be the last step in completing the SIB Project Area RA construction and can be completed with standard landscaping equipment and procedures for planting on riverbank slopes. See the Riverbank Design Technical Memorandum, Appendix D of the DCR.

3.0 CONSTRUCTION ACTIVITY CONSIDERATIONS

Construction equipment for the RA will, at a minimum, consist of floating plant, excavators, material barges, a hydrographic survey boat, and tugboat. The RA Contractor will need to use multiple floating plants that will be tasked with different operations that will vary from season to season. This work will include deep water dredging, shallow dredging, support of bank excavation and material removal, placement of cap materials (of various depths and design functions) and backfill, demolition activities, and structural improvements.

Outside of the immediate Project Area, the RA Contractor will require access to sediment and debris transload facility(ies) and a separate location for transloading fill, riverbank habitat substrate, and capping material to load barges. Specific information regarding the transload facility and its requirements (including permits) are summarized in the Transportation and Off-Site Disposal Plan (Volume II, Appendix O) and Specification Section 35 24 20 – Remedial Dredging, Barge Dewatering, and In-Water Transportation and Section 35 24 20.01 – Transloading, Upland Transportation, and Disposal.

The RA Contractor will require space for a field office and access to a floating dock to moor work skiffs, hydrographic survey vessel(s), and full-time tugboat. The field office will need to have parking for personnel and an adequate laydown area to operate equipment for delivery offloads, and storage of miscellaneous construction supplies. All permits applicable to the RA Contractor's upland activities would need to be obtained. Refer to Specification Section 01 52 00 – Construction Facilities.

3.1 CONSTRUCTION MATERIAL

The RD for the SIB Project Area includes a significant quantity of backfill, rock, habitat substrate, and erosion protection/chemical isolation material. These materials will be used to construct the cap erosion protection layer (EPL) and chemical isolation layer (CIL), shoreline revetments, vegetated soil covers on riverbanks, and outfall scour protection systems. Allowing for timely material procurement and supply of erosion protection materials has been a key consideration for the RD Team. To help alleviate this concern, where feasible, materials have been conformed to Oregon Department of Transportation (ODOT) standard material specifications. This is expected to broaden the number of suppliers with material readily available, reduce the cost of producing the materials, and reduce supply and delivery times. In addition, if suppliers are requested to produce large amounts of materials in anticipation of each In-Water Work Period, they will also have more confidence that the materials could be sold to others/elsewhere if the project cannot utilize the material or requires less material than anticipated.

Habitat mix materials (rounded gravel), which are required to be placed as cap EPL/leave surface material in shallow water, will be a specialty item for suppliers that will need to be produced for SIB Project Area RA and other RA projects in PHSS. Use of this specialty material cannot be avoided. However, the required volume of habitat mix for the SIB Project Area is relatively low and rounded gravel is available in the region. Advanced warning should be given to the suppliers so that sufficient supply can be generated prior to the In-Water Work Period.

Material sourcing, and the sequential handling of this material, will be a critical activity for the success of the project. Outlined below are key considerations for the RA Contractor in both procurement and handling of construction material required for the RA:

- Finalizing required quantities and estimated delivery schedule.
- Coordinating with suppliers on the estimated delivery schedule to identify if suppliers need to begin producing and stockpiling materials prior to the start of each In-Water Work Period.
- Understanding materials needed to complete work and need for potential third party transloading or stockpiling facility, to allow material to be barged directly to Project Area.
- Understanding how many suppliers are required to meet the project requirements.
- Understanding each supplier's stockpile and trucking/hauling capability and willingness.
    - Number of dump trucks and haul trucks available
    - Haul routes and possible cycle times
- Identifying a location to transload materials to a barge and subsequent coordination with the facility operator.
- Understanding how the transload facility receives and loads barges, onsite stockpiling capabilities, other project commitments and how these factors may impact barge loading schedules.
- Identifying where in the loading sequence amendment mixtures will be mixed in and developing a plan to execute.
- Evaluating where amendments will be added and mixed.
    - Quarry, transload facility, or material replacement barge
    - Wherever mixed, the RA Contractor will need to demonstrate that they will be able to mix the added material satisfactorily

3.2 CONSTRUCTION EQUIPMENT

The selected RA Contractor will determine many of the means and methods used on the project. Multiple floating plants will be required to accomplish the RA. It is anticipated that at least one dredge crane will be required for the deep-water dredging. Additional dredge plant(s) may either use crane(s) or excavator(s).

The placement of cap materials is expected to be completed with either a crane barge or excavator barge. A crane barge may be more efficient due to its larger bucket and swing radius. For some In-Water Work Periods, the RA Contractor may elect to have a third or fourth floating plant depending on schedule and work requirements. It is common in industry for these floating plants to be made up of a modular system such as “flexi floats.” Once assembled the RA Contractor would walk either a crane or excavator onto the barge. These modular barge systems can be assembled to use either spuds or anchors.

It is anticipated that the RA Contractor will have a separate, additional floating crane plant that can be used for capping, pile driving, demolition work and other related work. It is standard working procedure for cranes to be rented and walked onto a work barge. If a crane is used, a key requirement is to confirm the use of an appropriate crane chart for working on water. This applies to both rented and owned cranes.

Material barge needs will be high for SIB Project Area and PHSS overall. It is uncertain if the rental market in the region will be able to meet the demand, particularly if other projects are underway. The RA Contractor may have to source barges from outside the local market area. If the barges are leased and require mobilization along the coast to reach the Project Area, then the leased barges will need to be load-line American Bureau of Shipping (ABS) barges. Typically, these types of barges have a higher lease rate. It should be noted that modular barges are not typically used as material barges due to the configuration.

It is expected that many of the ancillary equipment items will be available for rent and purchase as needed. Ancillary equipment items anticipated to be needed for the project include excavators, environmental buckets, hydraulic buckets for excavators, work skiffs, and survey boats and equipment.

Depending on the other projects occurring at the same time in the PHSS, dump trucks and haul trucks may be at a premium. Haul routes and cycle times will influence the number of trucks needed. If other projects are underway, there is a risk that securing on-road haul trucks will be difficult and could make trucking a critical path activity.

Risk factors associated with equipment availability are influenced by market conditions. These risks, and mitigations, are summarized in the Current Risk Register and Status in Attachment D of the Cost Analysis Technical Memorandum (Volume I, Appendix K).

3.3 LOGISTICS AND CONSTRAINTS

Logistics for the successful execution of the SIB Project Area RA will require involvement and flexibility from all parties including but not limited to; the RA Contractor, shoreline facility owners/operators, material suppliers, equipment suppliers, other parties working in other areas of PHSS, transload facilities, and disposal facilities. The RA Contractor will develop an overall project schedule that shows the planned work sequence for the project, broken down by work periods. Shoreline facility owner/operators will need to share their critical operation information and schedules at the start of the project so the RA Contractor can incorporate it into the project schedule, where feasible.

Along with logistical requirements, the successful delivery of the RA must account for several constraints. These constraints include, but are not limited to:

- Design criteria for work operation separation and sequencing in order to minimize cross contamination, as required within the following plans (and reference specification sections):
    - Temporary Erosion and Sediment Control Plan (31 25 00 – Erosion and Sedimentation Control)
    - Dredging and Excavation Plan (35 24 20 – Remedial Dredging, Barge Dewatering, and In-water Transportation)
- Constraints associated with the protection of property and structures (01 19 50 – Protection and Maintenance of Property and Work);

- Water quality requirements, (addressed by the Water Quality Monitoring Plan [WQMP] and RA Contractors Water Quality Protection Plan within the Environmental Records Binder [ERB], 01 35 43 – Environmental Protection Procedures);
- Existing utilities (both in-water and riverbank) that may restrict/impact work operations (presented in the Drawings);
- Coordination with Oregon DSL for state-owned submerged or submersible lands that may or may not have waterway use authorizations in place (described in 01 31 00 – Project Management and Coordination);
- Shoreline facility owners/operators operational constraints (described in 01 31 00 – Project Management and Coordination); and
- In-Water Work Periods (01 14 00 – Work Restrictions).

The design constraints will need to be addressed in the RA Contractor's project schedule and RA Work Plan (RAWP) submittals. The project schedule will need to sequence and organize work in such an order to comply and satisfy all design constraints, including separating operations by a physical distance to minimize cross contamination risks or sequencing the work to accomplish structural improvements/changes required prior to the RA work. The RA Contractor will also need to address these design constraints in their RAWP to demonstrate their understanding of the contract documents and permit-equivalency requirements. The RAWP will also communicate the RA Contractor's plans for coordination with Oregon DSL, the City of Portland and other entities, as necessary, when restricting vessel movement through the Project Area.

See Specification Sections 01 31 00 for Project Management and Coordination (including Vessel Management Plan requirements); 01 32 00 for Construction Progress Documentation Requirements, 01 35 43 Environmental Protection Procedures; 01 41 00 Environmental Regulatory Requirements; and 01 41 26 Permits, Easements, and Right-of-Entry Requirements.

3.3.1 Impact of Vessel Traffic and Facility Operations

The SIB is an active waterway with multiple business facilities and varieties of operations. All of these will be impacted by RA implementation. Active and early communication between the RA Contractor and facility operators will be crucial to minimize this impact. Developing the overall project schedule will allow all parties to plan for operation to occur when RA work is not occurring at their property. Communication of any changes to the planned construction activities, facility operations, or the vessel schedule (both operational and construction), will also be critical to minimize impacts.

The RA Contractor will need to provide vessel notification as required by the U.S. Coast Guard, issue a Notice to Mariners, and provide the notification required by Oregon DSL. These notifications will state the names of the vessels that will be operating within the SIB, that the vessels are not self-propelled, and which marine channel is being monitored for communication.

Table 3-1 provides the RA Contractor with information to help plan and schedule the RA in the vicinity of each business. This information was obtained from surveys sent to each shoreline facility owner/operator in 2022, as described in the PDI ER (HGL, 2024b), and periodic follow up discussions during the RD.

Table 3-1 Shoreline and Overwater Structure Summary

Property/Facility/Status	Operations	Impacts Mitigation
Shipyard Commerce Center • Existing berths 306, 307 to be removed and replaced • Lagoon Wharf structure to be replaced, design by other party. • Dry dock has permanent anchor for security fence	Active year round	• Coordinate all RA activities with owner/operators. • RA needs to be completed prior to new pier construction.
Port of Portland • Existing dolphins and upslope mooring points removed • New permanent mooring piles • Berth 308 to be removed	• Base for Operating Dredge (Ocean) • Dredge deployed July-November	• Coordinate RA around dredge deployment • Temporary relocation of historic vessel.
Daimler Truck North America LLC Wind Tunnel supported by 4 steel pilings on shoreline	Year-round wind tunnel testing	Maintain 150-ft clearance on both sides of the facility during operations.
Anchor Park LLC	Upland Operations	Minimal Impacts
Swan Island Boat Ramp • City property, currently for sale • City Boat Ramp	Currently closed	Coordinate with the City of Portland's Harbor Master and Bureau of Environmental Services
Swan Island Dock Co. New breasting dolphin at Berth 311	Active marine terminal for barge deliveries, most active May to October	With coordination, potentially willing to support RA needs.
ATC Leasing No water access	Upland vehicle storage	No impacts if parking area is not impacted.
The Marine Consortium, Inc. • Marine response vessels • New mid-slope pinning walls constructed through existing pier	Full-time moorage and water access needed.	• Temporary relocation during RA work. • Coordinate partial demolition of pier with owner/operators. Incremental demolition/reconstruction could be accommodated
U.S. Navy Existing pier, may be removed in future	No waterfront operations	Access may be available with coordination.
U.S. Coast Guard • Pier and dock • Removal and replacement of existing fender piles • New toe wall • Mooring areas need dredging	Marine Safety Unit full-time moorage and access needed	• Temporary mooring relocation during RA • Shoreline access may be available with coordination.

3.3.2 Transloading

The logistics with the sediment/debris transload facility is another key element to the success of the project. The logistical considerations have been summarized in the Transportation and Off-Site Disposal Plan, Volume II, Appendix O.

3.4 DREDGING PRODUCTIVITY

Dredging production rates were estimated in the Dredging Design Technical Memorandum (DDTM) for a range of bucket sizes, equipment types (excavator and crane), and for different areas

of SIB with different accessibility. Dredging in open water has higher production rates, whereas dredging in shallow water areas, bank excavation, and work around structures have lower production rates. Refer to the DDTM (Volume I, Appendix H) for more information regarding production rates.

3.5 SEQUENCING OF REMEDIAL ACTION

The sequencing of the RA will be a critical item that will require coordination between all parties involved. Parties include, but are not limited to the RA Contractor, shoreline facility owners/operators, transload site operators, entity receiving treated water (if applicable), testing laboratories, material suppliers, and disposal sites. Coordination between parties performing concurrent remediation activities in the PHSS could help reduce potential conflicts and competition for resources. As mentioned in Section 3.3.1, the RA schedule aims to incorporate feedback from the shoreline facility owners/operators regarding times of year that will cause the least impact, when feasible. Constructability considerations that informed this review were also considered when refining the RA Schedule from Draft 50% to Pre-Final 90%.

The 90% RA Schedule has been developed to consider the sequencing of the RA and can be found in Figure 3-1 of the DCR.
